customary aperture in the boiler, its height being determined by the temperature of the steam. Assuming the working pressure of the engine 50 lb. on the cubic inch, that number is marked at the base of the tube; and assuming that an explosion is almost certain at a pressure of 150 lbs., that number is marked 6 in. higher on the tube, the range of the scale terminating at that measurement. The wire is loosely attached to the valve at, say 4 in. The customary safety valve is finally placed within the tube, a stud being attached and adjusted thereto, being under control. It is obvious that, as soon as the stud is raised upwards 4 in. in the tube, the wire must be detached therefrom; the weight being then let loose descends the inclined plane. The lid being thus relieved of its great weight must be raised upwards by the pressure of the steam, by which it will be also removed. *Patent abandoned.*

1479. T. BLINKHORN. *Improvements in the construction of steam boilers and engines.* Dated July 1, 1858.

This relates, 1, to increasing the heating surfaces of tubular steam boilers. This is effected by enlarging the diameter of the tubular flues, and placing therein water pipes which extend from the water space at one end of the boiler to the water space at the other end of the boiler. 2. To the flues and water pipes of tubular boilers, with the view to economise the fuel. Instead of allowing any of the gases to pass off by the chimney after they have traversed the length of the boiler he arranges a system of return flues, and places the smoke box and chimney at the fire-box end of the boiler. By this means he doubles the distances the gases travel through the flues, before they make their final exit into the chimney. The flues also contain water pipes which connect together the water spaces at the opposite end of the boiler. 3. To rendering agricultural engines compact, and simplifying their construction. To this end he places the steam cylinder within the shell of the boiler, and sets the same in a vertical position. A strong saddle piece, which serves to carry the bearings for the crank shaft, rests on the top of the boiler, and is firmly bolted thereto. Affixed to this saddle piece is the steam cylinder, which projects down into the boiler, and is therefore always kept at an equable temperature.

1480. T. RIDDELL. *Improvements in the construction of omnibuses, and in breaks to be applied to such and other wheel-carriages.* Dated July 1, 1858.

The object here is to provide accommodation for first and second class inside passengers. The body of the carriage is formed of two octagonal compartments, separated by a vertical partition. To the hinder compartment access is gained by a door at the back; but for the front compartment a side door is provided in one of the angles formed by the two octagonal figures. In the opposite angle are fixed steps for reaching the roof. It also relates to means of stopping omnibuses, &c., which are not described apart from the drawings. *Patent completed.*

1481. W. H. WIMSHURST. *Improvements in manufacturing sheet metal.* Dated July 1, 1858.

According to this invention either a cylinder or block of the metal to be formed into sheets is first cast in a mould, and then acted upon by a knife. When the cylindrical form is adopted the detail may be somewhat as follows:—A spindle or shaft of iron or other metal is provided, the ends of which are turned to fit truly into bearings. The centre of this spindle is fluted or turned to allow of perfect combination between it and the metal to be cut into sheets. This spindle is placed in a cylindrical mould, and the metal cast round it to the desired length and diameter. The spindle with the metal thereon is then placed in its bearings in a machine somewhat similar to a turning lathe, and made to revolve by steam or other power. A knife the length of the cylinder of metal is gradually brought near to the cylinder by means of wheel work or some other method (the cutter being supported on a sliding frame) and a continuous shaving or sheet of the metal thereby taken from the cylinder until the whole (or nearly so) is removed from the shaft or spindle. *Patent completed.*

1482. W. T. SMITH. *Improvements in and the combination of certain machinery or apparatus for winnowing, washing, sifting, and separating grain, ballast, sand, shot, minerals, and other materials.* Dated July 2, 1858.

This consists in attaching to a hollow perforated vertical shaft, one or more sieves or screens one above the other, which sieves or screens have outlets or mouths for discharging the completed material into compartments or fixed hoppers or shoots for simultaneously loading carts, &c. The upper sieve or screen is supplied with material by a self-regulating hopper. On the machine being set in motion the larger portions of the material pass out of the mouths of the upper sieve or screen, and are washed by water supplied to the hollow perforated vertical shaft and the self-regulating hopper, the smaller gravel or other material falling through upon the next sieve or screen, and so on until completed. The perforated shaft works in a collar or ring at top, and on a step or bearing at bottom. *Patent completed.*

1483. C. F. VASSEROT. *An improved wire-conductor for electro-magnetic machines.* (A communication.) Dated July 2, 1858.

This consists in using a cord made either of hemp, cotton, wool, flax, horse-hair, cloth, cane, or other material capable of being twisted, plaited, or rolled, and offering at the same time resistance and suppleness, and in surrounding the said cord with a wire of conducting metal. *Patent abandoned.*

1484. J. MORRIS. *An improved construction, or improvements in the construction, of copper rollers or cylinders for printing fabrics.* Dated July 2, 1858.

This consists in constructing such rollers, &c., so that when finished, portions of the interior bore will be enlarged, the metal removed from the enlarged parts of the bore reducing the weight, while the parts remaining of the smaller bore will give the required strength. The inventor first bores out the roller, &c., to fit the usual size of mandrill, and then enlarging the bore at each end, leaves a part of the middle untouched, and fixes at each end a copper ring (bored to fit the mandrill) which is inserted by pressure, and secured by closing over a portion of the end of the roller, &c. It relates also to copper rings in thin rollers, &c., for printing fabrics, and consists in forcing such rings in their places by pressure at the time such rollers, &c., are expanded by heat. After the rings are fixed the rollers, &c., may be placed in the machine to cut rings to the exact bore required to fit the mandrill, and to form the "rib" or part which fits in the groove formed in the mandrill. *Patent abandoned.*

1485. F. RICHMOND and H. CHANDLER. *Improvements in machines for cutting hay, straw, and other vegetable substances.* Dated July 2, 1858.

This invention was described and illustrated at p. 125, No. 8, of the MECHANICS' MAGAZINE (NEW SERIES.)

1486. E. LORD. *Improvements in looms for weaving, parts of which are applicable to other machines, and in machinery for making the crank shafts of looms and other machines.* Dated July 2, 1858.

This consists, 1, in the application of improved shaped friction wheels and palls to the letting-off motion of looms and to other machines, and in the machinery employed therewith. 2. In moistening the warp in its passage from the warp beam to the healds. 3. In supporting one or more of the lease rods on adjustable brackets. 4. In the application of friction wheels and palls of improved shapes to the taking-up motion of looms and other machines, the said friction wheels and palls being used in lieu of the ordinary ratchet wheels and clicks. 5. In an improved combination of parts applicable to the taking-up motion of looms for regulating the motion of the taking-up roller according to the increasing diameter of the cloth. 6. In the application of a locking apparatus to the vibrator for holding the warp tight when the lay or reed is beating the weft up into the fabric. 7. In making the circumference of brake wheels with a V-shaped groove or with a bevelled run, and the brake of a corresponding shape. Lastly, in the application of suitable machinery to bend rods or bars of iron into cranks to make the crank shafts of looms or other machines. This invention is not fully described apart from the drawings. *Patent completed.*

1487. P. R. HODGE and G. SPENCER. *Improvements in the means of preventing or regulating the recoil of springs used in railway engines, carriages, and station buffers.* Dated July 2, 1858.

This consists of an apparatus composed of cylinders provided with a piston working in a fluid contained in such cylinders. The fluid is, by compression, forced from one cylinder to the other through a channel connecting the two cylinders, in which channel there are valves to regulate the motion of the fluid. *Patent completed.*

1488. A. V. NEWTON. *Certain improvements in lamps.* (A communication.) Dated July 2, 1858.

The patentee claims: 1st. The use of a tube and burner arranged with a lamp or fountain, so that the flame which is fed direct from the burning material within the fountain, may serve as a gas generator to supply the illuminating flame that issues from the burner, and this he claims irrespective of any particular means which may be employed for supplying the illuminating flame with oxygen. 2, A case attached to the lamp or fountain, and provided with a cap, arranged substantially as shown in the patentee's drawings, that the illuminating flame may be supplied with the necessary amount of oxygen to produce a proper or perfect combustion. *Patent completed.*

1489. W. SELLERS. *Improvements in machinery for turning metal shafting or bars and cylindrical rings and cutting screws.* Dated July 2, 1858.

This consists in providing a revolving cutter head or chuck adapted to receive suitable tools or cutters and revolved by competent power. This cutter head has an opening in its centre through which the shaft to be turned, or the cylindrical ring or screw to be cut, is passed, and the said cutter head is caused to pass along the said shaft as it revolves, or the shaft is forced through the cutter head so that the revolving cutters shall remove the metal in the desired manner. The motion thus given endways of the shaft is communicated by screws acting on a slide rest or mandrill head. To support the shaft and prevent vibration between the cutter head and end of shaft double clamps are used, which hold the said bar centrally of the cutter head, and travel in a slide or rest. To sustain the parts of the bar, shaft, or ring that has been operated on by the cutters in the revolving head the patentee makes use of pairs of grooved rollers contained in head blocks set in cross slides and acting on opposite sides of the shaft, bar, or ring, to hold it central, and these head blocks are drawn together to clamp and hold the shaft (by said rollers) by a lever acting on a shaft with connecting rods to the head blocks. A blank shaft with a centre point is used between the rollers to guide the end of the shaft, bar, or ring to be turned. *Patent completed.*

1490. T. MELLODEW, J. DUXBURY, and E. LAYFIELD. *Improvements in machinery or apparatus for spinning and doubling or twining cotton and other fibrous materials.* Dated July 2, 1858.

This refers to the winding-on motion of mules, and consists in a method of governing the action of the regulating screw ordinarily used. The patentees cause a part projecting from the carriage to give rotary motion to a scroll or scrolls, or conical pullies, which being thus caused to rotate communicate a variable motion to the screw by a band or chain and suitable gearing; this arrangement is adapted both to hand and self-acting mules. The scroll in the former case, if caused to travel with the screw, is turned by apparatus fixed to the framing or other ordinary part. *Patent completed.*

1491. J. L. CLARK. *An improvement in electric telegraph cables or ropes.* Dated July 2, 1858.

To distinguish one wire from another when coated with gutta-percha, &c., a projecting rib or ribs, or groove or grooves, are formed longitudinally on or in the coating. By these means, when such coated wires are made up into telegraph ropes, the wires have each their distinguishing marks. *Patent completed.*

1492. D. LE SOUEF. *An improved shaft bearer or tug, and an improved manner of affixing the same to the harness.* (A communication.) Dated July 2, 1858.

This consists of a band of metal, the lower half of which supports the shaft, whilst the upper half is moveable on hinges, and, being intended to secure the shaft in its place, can be locked by a spring catch or pin. *Patent completed.*

1493. T. SCOTT. *Improvements in dressing, separating, and cleaning seeds, and in apparatus for these purposes.* Dated July 3, 1858.

This invention was described and illustrated at page 58, No. 4, of the MECHANICS' MAGAZINE (NEW SERIES). *Patent completed.*

1494. J. BIELING. *Improvements in fire-places or stoves.* Dated July 3, 1858.

This consists in conducting a supply of air from the exterior of the room to the fire by a passage in the wall or floor. The patentee causes this passage to communicate with an aperture on one side of the fire-place, and conducts a pipe or passage over or round the fire-place to another aperture on the other side of the fire-place. These apertures supply the air to the fire and to the room. The apertures have valves or regulators, and may be adjusted to direct the air so as to counteract accidental draughts in the room. *Patent completed.*

1495. S. LEES and J. JAQUES. *Improvements in the means for generating steam and economising fuel.* Dated July 3, 1858.

This consists in causing atmospheric air and the smoke or gases to be deflected on to each other so as to meet, the air being internal and deflected at the front of the fire-box, and the smoke or gases being reverberated and deflected at the back of the fire-box by apparatus arranged for the purpose. The invention is not described apart from the drawings. *Patent completed.*

1496. C. BURRING. *Improvements in apparatus for filtering liquids and other fluids containing impurities.* Dated July 3, 1858.

This relates to filtering liquids from the surface, and consists in employing a charcoal porous stone arranged to float upon the liquid. The inventor employs a pump or syphon for drawing the liquid up through the filtering medium. *Patent abandoned.*

1497. T. RESTELL. *Improvements in breech-loading fire-arms and ordnance, and in ammunition to be used in breech-loading arms.* Dated July 3, 1858.

This invention is not described in detail apart from the drawings. *Patent completed.*

1498. W. BOND and T. STANDING. *Improvements in apparatus for churning, mixing, and stirring cream, milk, and other liquids.* Dated July 3, 1858.

This apparatus consists of a vessel for containing the liquid, to the upper edge of which is fitted a bar or frame carrying a horizontal driving shaft which is furnished with a fly wheel and winch handle. Near the middle of this shaft is keyed a bevel wheel or pinion, which gives motion to a corresponding bevel wheel fast on the upper end of a vertical shaft working in the centre of the vessel, and supported in a footstep bearing placed on the bottom thereof. To the opposite ends of this central vertical shaft is keyed a series of radial arms, which form the bearings of a set of agitating shafts, fitted with agitators or open revolving frames. On the under side of the cross bar or frame, which is secured to the top of the vessel, is fixed a spur wheel which remains stationary, and into the teeth of which gear a series of spur wheels or pinions fitted one on to the upper end of each of the agitating shafts. These small wheels or pinions may either gear directly with the stationary wheel, or through the intervention of an intermediate wheel. On imparting rotatory motion to the central vertical shaft, by turning the winch handle, the radial arms, with their agitating shafts and agitators, will revolve round the central shaft, and through the intervention of the wheels on the agitator shafts will, at the same time, rotate round their own axis, the combined motion being the well-known sun and planet motion. *Patent completed.*

1499. J. CHISHOLM. *A method of disinfecting and deodorizing or treating sewage and other matters and structures and places.* Dated July 3, 1858.

This consists in the application of electric or galvanic agency to sewage, &c., whereby the foul gases are decomposed, noxious air or matters purified, and the products turned to useful account. *Patent completed.*

1500. J. G. JENNINGS and T. CULPIN. *Improvements in apparatus for measuring, regulating, and preventing waste when supplying fluids.* Dated July 3, 1858.

Here a cylindrical vessel is mounted on axes, on one of which is mounted the plug of the supply cock, which is so formed that the inclining of the vessel first in one direction and then in the other, causes the direction of the flow of water to be reversed, and the plug or valve is so formed that it will not quite close the passage, by which there will be a constant flow, even when the vessel is changing its direction of motion. Within the vessel there is a weighted piston moving fluid-tight by the aid of cupped leathers. The weighted piston moves on a piston rod which works fluid-tight through the ends of the vessel. The piston rod is of such length that when one end is protruding the other end is flush with the end of the vessel, and there are projections fixed near the ends of the piston rod, by which, when the piston comes against the collar at either end, it moves the piston rod and causes it to be withdrawn from the other end, and protruded at the end nearest that where the weighted piston has arrived, by which the opposite end of the rod is withdrawn from a catch or detent when the vessel completes its motion. To prevent waste a cylinder or barrel is used; the supply is introduced at one end, which is covered with a valve, and the outlet passage is beyond such valve, and to the valve stem is affixed a piston with a cupped leather. In the cylinder is a bucket on a rod. The valve rod spindle is formed with a narrow passage, which has a piece of wire passing through, but not filling the passage, the end of the wire is fixed on the end of the bucket rod; by this means the passage through the valve spindle is constantly kept open and clear as the valve spindle in its movement slides on the wire, and the movement of the bucket rod also moves the wire through the spindle. Between the upper and lower end of the cylinder or barrel is a tube by which the water which passes through the bucket in its descent is forced back into the main

Digitized by Google

When the bucket rod is moved, the pressure of the water supply will move the valve, and the water will flow to the outlet, till, by the passage of water or fluid through the valve spindle the space between the piston and bucket becomes full, when the pressure between the piston and bucket will close the valve. *Patent completed.*

1501. O. SABONY. *Improvements in treating and colouring photographic pictures.* Dated July 3, 1858.

The object here is to give the artist's work upon paper the softness, delicacy, and transparency which the same work would present upon ivory. This effect is produced by submitting the picture to the action of a hot metal plate, and covering the back of the picture by means of a brush with melted bees'-wax. *Patent completed.*

1502. J. G. JENNINGS. *Improvements in air-bricks, and in bricks for bonding hollow walls.* Dated July 3, 1858.

This consists in manufacturing air-bricks of clay and earth, by expressing the clay, &c., through dies. Numerous air passages are made through each brick horizontally, and arranged to any desired device. There are several modifications included. *Patent completed.*

1503. A. V. NEWTON. *Improvements in soldering irons.* (A communication.) Dated July 3, 1858.

This consists in the construction of hollow soldering irons for containing the solder and giving it out as required. *Patent completed.*

1504. J. G. JENNINGS and J. LOVEGROVE. *Improvements in water-closets, and in apparatus used in ventilating house drains or sewers.* Dated July 3, 1858.

This consists in constructing the basin with a conical outlet in the side or bottom, in which is fitted a hollow plug of metal, &c., made water-tight by a flexible ring. This hollow plug is made of such a length as to retain the water in the basin at a proper level, and any addition of water flows off through the hollow plug. The plug is fitted with an ordinary closet handle, and when lifted liberates the contents of the pan into the ordinary syphon trap. At other times the plug is to remain in position during any determined time, the object being to save water from sinks, waste-pipes, or other sources where the supply of water may be limited. To ventilate house drains and sewers, the patentees combine an air valve with the ordinary syphon trap and outlet valve, the valve being metal faced; the agent of ventilation being the variation in the temperature of the atmosphere and the water discharged into the drains. *Patent completed.*

1505. E. HAEFFELY. *Improvements in recovering oxides of manganese from products arising out of the manufacture of chlorine, and in raising commercial manganese to higher oxides.* Dated July 3, 1858.

This consists in recovering oxides of manganese by treating products arising from the manufacture of chlorine with lime or barytes, and so that there shall be an excess of such alkaline earth. The substance so treated is submitted to a temperature of 212° Fahrenheit. The lime is subsequently extracted by an acid. *Patent completed.*

1506. E. SIMONS. *Improvements in castors for furniture.* Dated July 5, 1858.

This relates principally to castors in which a sphere of metal is employed. The sphere is enclosed in a hemispherical cup, and prevented falling out of the cup by a ring screwing into the mouth of the cup, or by the mouth of the hemispherical cup being turned inwards. *Patent completed.*

1507. R. A. BROOMAN. *Improvements in the manufacture of cast steel.* (A communication.) Dated July 5, 1858.

The object here is to produce cast steel from iron in one operation, and the invention consists in cementing in a crucible fragments of iron of any description by a mixture composed of oxide of iron or of manganese, carbon, and potash, soda, lime, alumina, &c. To produce the required reactions between these substances it is necessary to mix them intimately by a suitable solvent, and to spread them as uniformly as possible among the fragments of iron. *Patent completed.*

1508. G. J. NEWBERY. *Improvements in the manufacture or production of coverings for floors, applicable also to the manufacture of table mats and other articles or coverings.* Dated July 5, 1858.

According to one mode of construction, this fabric is composed of threads, tapes, yarns, bobbins, twines, flexible gums, or compositions such as threads of india-rubber, gutta-percha, kamptulicon, &c., woven or interlaced together. These threads (when of fibrous material) are to be saturated and covered with any elastic gum, siccative oils, varnishes, or albumen, as a vehicle combined with pigment colours before being made into a fabric, after which such fabric may be pressed by passing through rollers slightly heated. There are various modifications included. *Patent completed.*

1509. J. HODGKINSON. *Certain improved machinery or apparatus for kneading dough in the manufacture of bread.* Dated July 5, 1858.

This consists in providing each end of the kneading trough with one or more pairs of crooked or bent arms or blades secured upon a short central shaft, only passing through the ends of the trough sufficiently to support the arms inside the trough; the shafts and arms are caused to rotate in opposite directions by spur gearing, or otherwise, actuated either by steam or hand power, so as to cause the arms to twist and turn over the dough in a similar manner as when kneaded by hand. *Patent completed.*

1510. T. WOOLNER. *Improvements in apparatus for feeding steam boilers with water.* Dated July 5, 1858.

This relates to the feed pipe for supplying the boiler with water, and consists in causing the water to pass through the interior of the boiler flues in a zig-zag direction, commencing at the fire-hole of one flue and making it exit at the fire-hole of another flue, and in all the flues passing beneath the fire-bars, so that the water in the pipe is not subjected to the heat of the flames until it has passed beyond the bridge of the fire-bars. The zig-zag bend is contained between the bridge and the extreme end of the boiler flue, and from thence passes into the next flue. The feeding end of the pipe has a valve opening inwards to the boiler, so that the water once admitted to the boiler cannot return; by this means the boiler and pipe is kept full. The water is heated by the apparatus and becomes ready for admission to the boiler, where it is quickly converted into steam. *Patent completed.*

1511. M. NELSON. *Improvements in propellers for vessels.* Dated July 5, 1858.

This consists in the arrangement of two propeller frames on each side of the vessel, moving in opposite directions, and carrying buckets hinged on one of the vertical edges, so that the buckets can turn down against the reciprocating frames in either direction. And the patentee makes use of moveable blocking devices by which the buckets are sustained when open, and allowed to turn down towards the stern when the vessel is going forward, or towards the bows when the propellers are giving sternway to the vessel. The method of actuating these propeller frames may be varied. *Patent completed.*

1512. J. GREENWOOD. *Improvements in marine propellers.* Dated July 5, 1858.

This relates to floats or float boards, either disposed around a circular wheel of the ordinary form, or applied as propelling surfaces upon arms, or as vanes radiating from a central axis or shaft, which may be placed either horizontally at a right angle with the keel line, or placed in the centre of the vessel, in a well-hole; or the axis or shafts may be placed horizontally in a line with the keel, or transversely at a right angle with the keel line. *Patent completed.*

1513. J. T. DAVIES. *An improved lock.* (A communication.) Dated July 5, 1858.

This relates to that class of combination locks which have no key-hole, and consists, 1, in the peculiar construction of the key, and of the corresponding parts of the lock, by which the key can be opposed directly to the lock, and the lock operated without referring to any index signs or figures. 2, in the use of two working shafts, one within the other, one of which has a rotating movement in which every point describes a circle, while the other has a rectilinear movement only, both produced by the use of the key making movements resulting from the action of the key bits, while the separate movement of these shafts when moved by hand, and without the application of the key, result for each given point irrespectively in a circle and straight line, thereby giving clue of the extent of the movements of the sliding tumblers. *Patent abandoned.*

1514. J. DODD and T. PHILLIPS. *Improvements in the slide valves of steam engines.* Dated July 6, 1858.

This invention was described and illustrated at page 106, No. 7, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1515. H. HUGHES. *Improvements in gauffering and crimping machines, parts of which are applicable to the manufacture of continuous belts and shutters.* Dated July 6, 1858.

This consists in forming a continuous band from plates or strips of metal, parts of one side of each being cut away, and the metal between the parts so cut away being twisted at right angles to the face of the plate and holes pierced in the twisted end for the reception of a rod of metal or of links to hold the plates together, and so form a continuous length. For gauffering and crimping machines a head of the shape required to suit the gauffre crimp or plait is added or formed on the edge of each plate, and a nick or part is cut away longitudinally through the centre of the rising edge of each plate to receive a steel rod or bar, or a chain; the effect is to form a groove in the centre of the material to be crimped or gauffered. *Patent completed.*

1516. W. E. NEWTON. *Improvements applicable to roller blinds.* (A communication.) Dated July 6, 1858.

This consists in the application of india-rubber to the pulley of the window blind roller over which the endless cord for turning the roller is to pass, by which sufficient friction is given to the cord to make it bind on the roller, and cause the same to rotate, but at the same time to prevent the blind from accidentally unwinding. This arrangement admits of dispensing with the lower bracket for straining the cord, and thereby allows the cord to hang loosely. The roller, which is cylindrical, is simply to be cut to the right length, and the ends are received in curved or semicircular sockets. *Patent completed.*

1517. J. DAVIS and T. EVANS. *Improvements in engines to be actuated by steam, air, or gases.* Dated July 6, 1858.

Here the cylinders are caused to oscillate upon hollow trunnions, the steam being supplied through the trunnions to the cylinder, and distributed alternately to the steam passages by a fixed valve placed in the valve chamber, the rear face of which is always in contact with the steam from the steam pipe, the other face fitting close over the steam and exhaust ports in the side of the cylinder. This fixed steam valve has ports or openings cut in its face at regulated distances apart, also a hollow recess. As the cylinder oscillates, these openings in the fixed valve connecting with the ports of the steam passages alternately supply each with steam, while the recessed part puts the exhaust in connexion with either steam port. *Patent completed.*

1518. J. BUCHANAN. *Improvements in propelling ships, vessels, and boats.* Dated July 6, 1858.

This consists essentially in the use of a propelling wheel, of large diameter, and fitted with inclined or screw propelling blades, which wheel or drum is so disposed that its lower portion shall protrude through the bottom of the vessel or ship. This wheel is placed right across the ship on a horizontal propelling shaft running fore and aft, either in the line of the keel, or at a short horizontal angle with the keel. This divergence from the keel line is for enabling the force of the propelling blades to act right in the line of the keel. This wheel is connected to the engines in any convenient way. *Patent completed.*

1519. W. A. SMITH. *Improvements in machines for making bricks, tiles, or pipes of clay.* Dated July 7, 1858.

The patentee claims the using of flannel, &c., to cover the pistons used in brick machines, and the use of moulds running horizontally under channels through which clay is forced into them, the said moulds being open at top and bottom, and moving either in a continuous train, or in a reciprocating manner, together with the apparatus for discharging and carrying away the bricks or other articles, and supplying the pallet boards. *Patent completed.*

1520. H. C. SCHILLER. *Certain improved apparatus for laying down and recovering submarine telegraphic cables.* Dated July 7, 1858.

Here the vessel carrying the cable is to tow astern a requisite number of small steam-vessels or steam-tugs, travelling at the same speed, and connected with her and with each other by hawsers, chains, &c.; for keeping them at a given relative distance from each other, the weight of the hawsers or chains between the vessels being supported by means of buoys or floats. Each of these small steam-vessels or tugs is to carry a sling, the upper end of which passes over a windlass on board, which is connected to the steam engine, and the lower end carries a block with two sheaves or pulleys (one above the other), between which the telegraphic cable passes. Slings may also be attached to the buoys if necessary. Each sling is to be attached to its preceding and succeeding ones by diagonal traces or other gear. These slings are to be of a proportionately greater length relative to their respective distances from the leading vessel (which carries the cable), so as in the division of their aggregate distances from her, and that of the extreme of each from the surface, to produce the angle requisite for the safe suspension, at intervals, and delivery of the cable at the lowest soundings required, the shortest sling being nearest to the leading vessel, and the longest sling furthest from it. In recovering the cable, the same apparatus is employed, but reversed. *Patent completed.*

1521. J. J. FLORANCE. *Improvements in reels or spooling-wheels.* Dated July 7, 1858.

This consists in combining the several parts so that these reels take up less space than those hitherto used for the same purposes, and offer also more regularity and swiftness of motion. A suitable frame in which turns a main arbor is provided with a penion receiving motion by gearing, endless bands, cords, chains, &c., from a large wheel. The said main arbor has a fly wheel for steadying the motion, and with another large wheel which, by endless bands, chains, &c., transmit the motion to the spindles of one or more cops or bobbins turning in suitable bearings in the frame. The relative positions of the various parts, and particularly of the spindles from the centre of motion, are regulated by set screws. *Patent abandoned.*

1522. P. MERCIER. *Improvements in the treatment of peat, and in preparing the same for fuel.* Dated July 7, 1858.

This relates to a system of preparing peat to render it more serviceable as a fuel. The peat is first cut from the ground by any cutting tool, but the apparatus which the inventor prefers to employ consists of a tool or cutter having four cutting edges; to this tool a descending motion is imparted, whereby it enters the peat, and divides it by its four cutting edges, so as to enclose a cube of peat within it. Another cutter then passes along the base of the cube, severs it from the ground, when the cutters are elevated, carrying with them the detached cube of peat. The peat is now to be dried, which is effected by enclosing it in bags, baskets, &c., of a pervious nature, which are to be placed in a centrifugal machine, and the moisture is then expelled by centrifugal force. The peat is subsequently placed in a vessel which revolves on a vertical centre or pivot and within which rotates a series of arms whereby all the particles of the peat are mixed. From this machine the peat may pass to a pair of vertical millstones, whereby it is crushed and thoroughly pulverised. The peat having been sufficiently prepared by the millstones is forced by scrapers down a central passage into pressing and moulding machines. *Patent abandoned.*

1523. J. HOLLAND and F. POTTS. *Certain improvements in ornamenting metallic bedsteads, and which said improvements are also applicable to the ornamenting of other metallic surfaces.* Dated July 7, 1858.

This relates to a method of ornamenting metallic surfaces, so that they may have the appearance of being ornamented with gold or silver leaf. Also to a mode of heating the iron parts of metallic bedsteads that it may be desired to so treat, and this portion of the invention has for its object the imparting to the parts so treated the general appearance of enamelling. For the details, we must refer our readers to the specification. *Patent completed.*

1524. W. CLISSOLD. *Improved machinery for cutting or rasping dyewoods.* Dated July 7, 1858.

The block of dyewood is set up in a conical or trumpet-mouth case, through which project rotary saws or rasping surfaces, slots being made for that purpose in the conical case. Above the case is a follower for feeding the wood to the saws, and giving it at the same time a slow axical motion; the saws being caused to run with rapidity will rasp off the surface of wood, and a constantly changing surface being presented to the saw teeth, the end of the block of wood will be quickly reduced to a conical point, which will be sustained until the whole of the block is rasped away. *Patent completed.*

1525. T. JAMES. *Improvements in treating sewage matters.* Dated July 7, 1858.

At the mouth of a drain or sewer the inventor places a receiving vessel hermetically closed to the atmosphere, but communicating through perforated sides and bottom with an air-tight well into which the liquid portions of the sewage will flow through the perforated sides and bottom of the receiver. He pumps this liquid portion up into covered filtering vessels, through which the liquid in a filtered state is allowed to flow into the river. He removes the more solid contents from the perforated vessel through the tubes opening into exhausted tanks in barges brought alongside the first receiving vessel. The barges convey away the tanks containing the more solid matters to be used as manure. *Patent abandoned.*

1526. G. A. B. CHICK. *An improvement in the preparation of graphite, or plumbago, or black lead.* Dated July 7, 1858.

This consists in grinding the black lead, &c., to a fine powder, and mixing it with a small quantity of olive oil;

Digitized by Google

the compound is pressed together, and after some days it is again ground, and is then ready for use. *Patent completed.*

1527. G. T. Bousfield. *Improvements in apparatus for ironing linen and other fabrics.* (A communication.) Dated July 7, 1858.

Here the iron is constructed with a smooth iron or face on one side, and with two spaces in which metallic rollers revolve on the other side, the metallic rollers projecting slightly beyond the face of the iron. The iron at its two ends is connected to the handle by pins or pivots, so that the iron may revolve in the handle; and attached to the handle there is a spring catch which enters recesses in the iron, so that the iron may be retained with either face downwards. The flat side is to be heated, and then the iron reversed, so as to iron with the other side. *Patent abandoned.*

1528. J. D. Weston. *Improvements in rolling iron for the manufacture of bolts and pins.* Dated July 7, 1858.

To make bolts or pins with projecting angles, &c., on the stems under the heads, the patentee first rolls the iron in the usual way into an elliptical or other section; he then passes it through a pair of rolls in which the shape of the angle or elevation required on the neck of the bolt or pin is indented at regular distances. The bars being thus rolled he cuts them up by the usual modes in lengths for the formation of bolts or pins. *Patent completed.*

1529. A. W. Sleigh. *Improvements in the construction of floating sea barriers or artificial beaches, breakwaters, and batteries.* Dated July 7, 1858.

This consists in making the floating caisson in which the inclined plane rests of a triangular shape, of which the base line which floats on the water is the longest, by which much greater buoyancy of the whole structure is obtained, and the caisson moored on each side without revolving on a centre of motion. It also consists in adapting these caissons for floating batteries. Reference to the drawings is required for a clear description. *Patent completed.*

1530. J. F. Stanford. *A new and improved method of and apparatus for applying heated air in drying corn, hay, and other like articles, in the stack or otherwise, and in drying goods, and in heating and drying rooms and buildings.* Dated July 8, 1858.

The inventor accomplishes his invention by means of a stove and blower, and certain appliances connected therewith. *Patent abandoned.*

1531. J. Marland and J. Widdall. *An improved self-acting hook or holder to prevent accidents in lifting, hoisting, or winding at coal-pits, or other similar purposes.* Dated July 8, 1858.

The part of the hook to which the rope or chain is suspended is jointed at one end, and held or clipped at the other by a catch, acted upon by a spring when within the bounds of safety, which catch gives way and releases the hook when the latter too nearly approaches the pulleys or drums by its coming in contact with a bar or projection. The invention is not fully described apart from the drawings. *Patent completed.*

1532. H. Gidlow. *Improvements in breaks for steam engines.* Dated July 8, 1858.

This relates to that class of steam engines which require to be frequently stopped at certain defined positions, as in the case of mining engines. The patentee applies a self-acting break, having one end attached to a chain or band passing over and fastening to a pulley, which is either fixed to the shaft of the fly-wheel or other counter shaft. The said chain coils around the pulley to which it is connected when the engine is in motion, and being regulated to the required length causes the break to act just as the receptacle or frame arrives at its destination, either above or below. The patentee also applies to the aforesaid steam engine a self-acting apparatus for lifting off the excentric rod or rods, so as to shut off the steam or close the port holes of the steam cylinder either before or just as the break is beginning to act. *Patent completed.*

1533. J. B. Booth and R. Ashworth. *Improvements in the means of stopping or retarding the progress or velocity of railway carriages.* Dated July 8, 1858.

These consist of an improved self-acting brake. To the tyre of the wheel the inventors place a shell, which is acted upon by a brake formed of segments of wood connected to radial arms, which are raised up when required so as to press the segments with great force against the interior of the shell, the radial arms being governed by a nut and worm wheel and pinion, worm and worm wheel, or spiral spring. Also in certain arrangements for giving a dead stop to the revolution of the wheels of railway carriage wagons or tenders, by placing in the boss of the wheel, or any part of the axle, a sliding catch, and upon the guard plate a sliding plate with ratchet tooth, the position of both catch and tooth being adjusted by cams, so that in one position the wheels may turn either way as desired, or placed so that the catch and tooth may come in contact with each other, and give a dead lock to the wheels. *Patent abandoned.*

1534. P. F. Demoulin and J. Cotelle. *Improvements in treating the heavy oils obtained from the distillation of coals, schists, and other hydro-carbons.* Dated July 8, 1858.

Supposing the patentees have to act on 100 kilogrammes of the said oils, they introduce them in a vessel which can be properly closed, and ultimately mix with the oil 50 litres of water; 1 kilogramme of chloride of lime; about 2 kilogramme of soda salt, and ½ kilogramme of manganese. The whole is then violently shaken, say for about an hour, and is then left to settle for about twenty-four hours, after which the supernatant oil is decanted from the sediment, and distilled, so as to bring the oil to a specific gravity of about 90° to 92° of Vignie's areo-meter, after which it is submitted to rectification by mixing with about 100 kilogrammes of the oil, and about 25 kilogrammes of resin oil. By this latter operation the oil is deprived of its gummy parts, and is at the same time entirely deodorised. *Patent completed.*

1535. T. T. Chellingworth. *A high-presure steam engine.* Dated July 8, 1858.

This consists, 1, in the arrangement of the steam ports, eduction port, and slide valve of steam engines, so that the steam, having been cut off after the completion of a portion of the stroke, is expanded the remaining portion, and the whole of the return stroke. 2. In fixing the trunk to the piston by a conical bolt, with an eye at one end, to which is attached the connecting rod for working the crank, and also in forming and arranging the stuffing-box, through which the trunk works, so that it may project inside the cylinder, while a corresponding recess is cast in the piston, so that they may fit into each other with only a very small space between them. *Patent completed.*

1536. P. R. Hodge. *Improvements in brewing fermented liquors, and in treating materials used therein for purposes of food.* Dated July 8, 1858.

This consists in crushing the malt, subjecting it to a heat in chambers, keeping it in motion, and drawing off the steam or vapour arising from such process. The patentee constructs one or more closed vessels for containing the malt, and others for containing the hops, which are previously hackled, torn, or ground, that heated water or steam may be forced through the same upwards through a wire gauze bottom. The temperature of these vessels is kept up by a steam casing; the malt is kept at a temperature of about 150° Fahrenheit, and the hops at a much higher temperature. The hops are hackled, or torn, by cutters or hackle pins fixed on revolving cylinders so that such teeth or pins pass between an iron grating which forms the bottom of the hoppers. The patentee, in some cases, admits high pressure steam to the surface of the extract or wort, to volatilize the oil or other products, and thereby preserves the aroma of the malt, and after the other impurities are cleared are drawn off, he lets the liquor into suitable vats or vessels for cooling and admixture in due proportions. There are modifications included. *Patent completed.*

1537. R. Smith. *An improved adjustable pipe tongs.* (A communication.) Dated July 8, 1858.

This consists in so constructing the adjustable tongs that the strain consequent upon the use of the tongs shall not separate the jaws by slipping or moving the pivot fixed to the one jaw in the slot of the other jaw. Those parts of the hooked end of the straight jaws by which the pipe is grasped are made in the usual well-known manner. The pivot which holds the tongs together is secured in the straight jaw piece so that they can turn on each other, and is provided with a collar which is partly recessed into the inner side of this jaw piece. The inner side of the hooked jaw piece rests against this collar, and that part of the pivot passing through the slot is flattened to fit the slot, and to prevent its turning round therein. Now, instead of having the two outer surfaces of the tongs parallel with each other at that place where the pivot holds them together, and securing them with the common nut and washer, the outer surface of the hooked jaw piece has an inclined plane, likewise slotted, which may either form a part of or be fixed to the jaw piece. This inclined plane inclines towards the hooked end of the jaw, and the washer fitting upon it is tapered to correspond with the inclined plane, so that the outer surface of the washer is at right angles with the axis of the pivot. A projection on the under side of the washer fits into the groove and prevents the washer from turning. That part of the pivot projecting beyond the washer is screwed in the usual manner to receive the nut by which the tongs are held together. It will be obvious that any strain which tends to move the pivot in the slot so as to increase the distance between the jaw hook and the pivot, would have to move the inclined plane of the washer up the inclined plane of the jaw piece, which cannot be done without breaking the pivot or stripping off the nut by direct tensile strain. *Patent completed.*

1538. S. Samuels. *Improvements in laying submarine telegraphic cables.* Dated July 8, 1858.

This consists in passing the cable from the ship into the water through some convenient opening made in the ship at or near the centre of the vessel. The inventor proposes to pass the cable from the deck down an inclined pipe or way, extending from the deck, to a hole near the keel. This tube or way is to be provided at top and bottom with antifriction rollers. *Patent abandoned.*

1539. S. Harrison. *Improvements in ovens.* Dated July 8, 1858.

This relates to ovens which are usually constructed of sheet or cast iron, and are heated by the flame of incandescent carburetted hydrogen gas. The patentee combines two, three, or more ovens together, and so arranges them that the heated gases and vapours are conducted over, under, or around the ovens in a serpentine direction. *Patent completed.*

1540. R. J. Crickmer. *Improvements in treating the sewage of London and neighbourhood.* Dated July 8, 1858.

This invention was described at page 106, No. 1825, vol. 69, of the Mechanics' Magazine.

1541. R. G. C. Fane. *Improvements in treating sewage, and in apparatuses to be employed therein.* Dated July 8, 1858.

This consists in constructing intercepting wells beneath sewers and drains, in placing in such wells receiving vessels perforated on all sides, and at bottom; in erecting a stop bridge on the further side of each well; in providing a passage upwards from each well on the further side of the bridge; and in providing suitable sealed openings through which to get at, remove, and replace the receiving vessels. Filtering, deodorising, or disinfecting agents may be employed in the wells. *Patent completed.*

1542. M. Scott. *Improvements in constructing breakwaters, and other like structures.* Dated July 8, 1858.

In constructing wood piles with screws, the same are each fitted with a worm or screw, formed by preference of T or angle iron. The angles of the wood piles are first removed, and then the iron bar (being heated) is wound spirally around the lower end, and shrinks thereon tightly. In constructing breakwaters, &c., by frames resting on the bottom, and fitted in with stone, the patentee sometimes prepares bearings for the frames when below the water-mark of spring tides, by divers, who lay flat stones in suitable positions, and then the measurements for constructing the frames can easily be taken from these foundations, and the frames may be built at a distance, and when finished brought to their places, and erected on the foundations already prepared. The invention is not fully described apart from the drawings. *Patent completed.*

1543. G. Collier. *Improvements in means or apparatus for the drying of wool and other fibres.* Dated July 8, 1858.

Here the fibre to be dried is conducted to, and so as to be held between, endless aprons formed of open work, and which pass over open cylinders through which air, heated or otherwise, is forced by fans or other suitable means, so as to cause it to pass fully amongst and through the fibre whilst it is being carried by the aprons over the open cylinders. *Patent completed.*

1544. G. Sampson. *Improvements in means or apparatus employed in the finishing of woven fabrics.* Dated July 8, 1858.

Here in place of the jets of steam as they come from the steam pipe acting directly down upon the fabric, the cover of such pipe forming a chamber to confine the steam and cause it to act more fully on the fabric, is provided with an internal roof or guard upon which the steam first acts, and rising above and within the lower edges of this internal roof or guard, yet so as to admit of the dry steam rising between them, there are side boards or frames. The lower edges of these side frames lead to gutters by which the particles of water become separated from the dry steam, and are conducted away by pipes, and the dry steam alone acts on the fabric. Other numbers of side plates or frames may be employed, each overlapping the other, yet so as to leave passage for the steam to rise upwards towards the centre of the chamber whilst the more liquid parts are conducted to the troughs or gutters. The inventor also applies pressing rollers to press the fabric after passing from the steam chest to the winding-on roller. Also the improvements relate to applying within such steam cover a vessel for sizing or other matter, and in causing the steam to open into such sizing matter to cause the sizing matter therein, or essential part thereof, to flow therefrom in the vapour, and in such manner and by means as referred to, to be conducted to the fabric, whilst any more liquid particles will be conducted away by the troughs or gutters as before described. *Patent abandoned.*

1545. W. Simons. *Improvements in or connected with ships or vessels.* Dated July 9, 1858.

This comprehends various improvements in the construction of ships, in the arrangement or construction of their masts and of parts connected therewith; in the mode of moving or anchoring them, and in the construction of boat anchor and other davits. The invention is not described apart from the drawings. *Patent completed.*

1546. G. Parsons. *Improvements in apparatus for the prevention of injury to, and the sudden bursting of steam boilers.* Dated July 9, 1858.

The patentee connects with the feed pipe, from a force pump of the engine, a cylinder in which works a piston. This cylinder is fitted with a whistle, and has an opening communicating with a pipe descending into the boiler; a steam pipe from the engine is also connected with the cylinder at the back of the piston. The action is as follows:—When the feed pump is in action, the water therefrom will force back the piston in the cylinder so as to cover the whistle, and allow the water to pass into the boiler; but should by accident the feed pump fail to supply water, then the piston will be forced forward in the cylinder by the pressure of steam from the engine, so as to uncover the whistle and sound the same, so as to give notice that the supply has ceased. To prevent explosion from the water falling so low as to expose the boiler plates to the action of the fire, and also to secure the escape of steam when above any desired pressure in the boiler, he places on that part of the boiler which is most exposed to the action of the fire a rising surface or cone through which passes the end of a rod, secured and held in its position by a fusible metal plug. On the other end of the rod is placed a loose piston or valve weighted down to any required pressure by a spring, and placed in a cylindrical cover, on the outside of the boiler in which it works. The cylinder is made in two parts bolted together, and a padlock is fastened through one of the bolts to prevent the removal of the cover or access to the spring after it is adjusted to the pressure desired. The pressure on the spring is regulated by a set screw on the end of the rod. By this arrangement the steam is allowed to blow off at a given pressure by the lifting of the piston or valve, and should the water fall so low as to expose the boiler plates to the action of the fire, the metal plug which is fusible at a low degree of temperature will melt, and liberate the rod and piston or valve, and allow the steam in the boiler to escape. *Patent comptd.*

1547. J. Broadley. *Improvements in means or apparatus employed in weaving.* Dated July 9, 1858.

This relates, 1, to means for giving motion to rotary shuttle boxes. 2, to so arranging parts in connection with rotary shuttle boxes operated by straps or bands, so that when, by the sticking of the picker or other derangement, a stopping of the working of the series of boxes takes place, the pulley wheel operating such band may be permitted to slip so as to prevent breakage. 3, to the construction of a series of rotary shuttle boxes or chambers in order to give additional strength thereto. 4, to means of obtaining pattern surface for operating to select rotary or other shuttle boxes, and which is also applicable as the selecting means for other purposes in weaving. 5, to apparatus for stopping the loom when weft fails, as adapted to picking successively from the same side, or what is called pick and pick. 6, to means for selecting the order of picking. *Patent completed.*

1548. F. Sang and T. W. Rammell. *Improvements in the means of conveying letters and parcels from one place to another.* Dated July 9, 1858.

Here the letters or parcels are placed in suitable receptacles or carriages to travel within tubes, and are propelled in the desired direction by the superior pressure of the atmosphere behind the carriages over that in front, which is rarefied to the requisite degree by pumping engines, so that the carriage or train of carriages within the tube is conveyed from one station to another. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MARCH 11, 1859.

THE NEW IRON SCREW FRIGATES.

ALL the world knows now what was meant by Her Majesty's Ministers when they spoke of the "re-construction" of the navy, which proved to be no very grand affair, notwithstanding its high-sounding designation. But it is doubtful whether all the world, or even any considerable portion of it, has yet reflected upon that part of Sir JOHN PAKINGTON'S late speech in which a real and most costly re-construction was for the first time shadowed forth. "We have no option," said he, "in the discharge of our duty, but to commence the construction of iron-cased ships." In those words we find the beginning of a change which will ere long cost the country a far greater outlay than even the introduction of steam machinery into ships of war has occasioned. The cost of a 36-gun frigate, prior to the use of steam, was about £40,000; the cost of a 36-gun steam frigate is about £80,000; but the cost of a 36-gun iron-cased frigate will not be less than £200,000 or £250,000. So that where steam has cost its tens of thousands, iron will cost its hundreds of thousands. There is no exaggeration whatever in these estimates. We cannot give the exact cost of 36-gun ships of each kind, but we know that the *Pique*, a 40-gun sailing frigate, cost £42,844, and the *Curaçoa*, a 31-gun screw frigate, cost £73,819; and these figures are sufficient to show that £40,000 and £80,000 may be taken for the 36-gun sailing ship and screw ship respectively with no great risk of error. We are also fully prepared to affirm that £200,000 may be taken as a minimum for each of the 36-gun iron steam frigates which are now to be constructed. The subject is therefore worth a little consideration, and as it is exceedingly probable that these vessels will be built wholly of iron, let us first glance at what has heretofore been done by us in the way of building iron ships of war.

Between the years 1843 and 1850 the British Government expended (notwithstanding all that Mr. SIDNEY HERBERT has been pleased to state in the House of Commons to the contrary) some three-quarters of a million sterling in the construction of iron ships of war of different classes, varying in size from 300 to 2,000 tons, and carrying from three to eighteen guns. In 1850 experiments instituted at Portsmouth were reported to prove that "whether iron vessels are of a slight or substantial construction, iron is not a material calculated for ships of war;" and the confidence placed in the judgment of the naval officers superintending the experiments was such that, although it had been intended to build a large fleet of these ships, the orders for their construction were at once countermanded, and the ships already in existence were either sold or disarmed. In 1854 the French wooden floating batteries were designed, in which thick solid plates of iron were employed as armour upon the sides; and in the next year the English wooden batteries were built from the French drawings. But as these vessels drew nine feet of water, and it was reported that nothing deeper than eight feet could pass within the forts of Cronstadt, it was determined to construct similar vessels of iron as a means of securing the lighter draft. The *Erebus*, *Terror*, and *Thunderbolt* were accordingly designed and built in an incredibly short time, at a cost of about a quarter of a million; but just as they were completed the war terminated, and their services were not needed. At about this time, also, 47 iron mortar vessels of very light draught were constructed, at a cost of about £120,000; these also were too late for service. Recent experiments on the iron floating batteries seem to show that their sides are far too slight to withstand the shock of the projectiles thrown against them, and that in securing the desired light draught of water, their efficiency as shot-proof ships has been sacrificed. In their present state, therefore, these ships are of little value, even as block-ships; and it becomes a question whether their sides could not be so strengthened as to remove the defect, without bringing the ports too near the water.

That our experiments with iron war ships have hitherto been failures is clear enough, and it behoved any Government taking the matter in hand again to proceed with caution. That they should take it in hand at all after such experience, proves more clearly than any arguments we could use, that wood fails to meet the requirements of modern naval architecture. The difficulty of procuring timber of sufficient size, the length of time which such timber is required to stand to season, and its perishable nature under the best of circumstances, all make it desirable to adopt every possible means to supply its place in large ships with some other material. All our experiments show that we can only obtain great speed in our war ships by giving them great length; and the ship of war which, at the commencement of the year, is thought to be of extravagant dimensions, is by the end of it far outstripped by new designs. Such ships are necessarily very costly, and to expend hundreds of thousands of pounds on materials which will be devoured by dry rot in the course of ten or twelve years, seems almost like throwing money away; yet in modern ships, *rapidly built*, this is certainly the case. With these facts before them, the present Admiralty have determined to carry out the intentions of their predecessors, and make one more attempt to replace tough oak by tougher iron. In giving effect to their determination, they have, to use the language of Sir JOHN PAKINGTON, "called upon the most competent parties in different parts of England connected with private trade to give their designs and counsel." They have likewise called upon the present master shipwrights of the dockyards—all of whom are trained and experienced naval architects, and deserve the compliment paid them by the First Lord—to furnish designs. They have imposed no restrictions, we believe, on the architects in respect to the dimensions of the ships, or the power of their engines, but have simply stipulated that they should carry 36 guns of a certain calibre, with the necessary complement of men and provisions for four months, at a speed of 14 knots per hour, and that they should bear armour upon a portion of their sides, consisting of 1,000 tons of 4½ inch wrought-iron plates, backed by two feet of solid timber. The idea of protecting only a portion—the middle portion—of the ship by the iron plates, is a most important one. It seems to us to give an air of practicability to the scheme which it never had before. If the extremities of the ships had been burdened with these enormous weights, the ships would never have been seaworthy: they would necessarily have been as sluggish and dull as logs. But the concentration of the weights in the midship part of the ships will give them as much freedom and easiness of motion as can be desired. It will be necessary, of course, that the proportion between the displacements of the protected and of the unprotected parts of the ship shall be such that if the latter be riddled by shot and water-logged, the ship may still float at a safe draught.

It is, let us now say, impossible to discuss this question without observing that the Admiralty have taken upon themselves an exceedingly delicate task by the invitation which they have given to private builders to furnish designs for the proposed frigates. That such a proceeding will be popular with superficial observers, there cannot be a doubt; but we believe it will prove a source of much jealousy and discontent among shipbuilders, without resulting in any advantage to the nation. That the Government would have acted wisely in proceeding to build costly iron ships, without consulting private builders of known skill and experience, we do not for a moment believe; because, although we have excellent grounds for confidence in the ability of the Surveyor of the Navy and his assistants to perform what is now required, the public may doubt that they possess a sufficiently full and practical acquaintance with the art of iron-shipbuilding. But we have no hesitation in saying that the Admiralty have taken an imprudent step in calling upon merchant shipbuilders for designs of ships of war, with the nature and qualities of which the very best of them are most imperfectly acquainted. Instead of exciting the hopes, and possibly the intrigues, of eight or ten private shipbuilders, by inviting them to undertake a work for which none of them can be wholly competent, they should have called to their aid one or two men of known eminence as iron-shipbuilders, and who are known to be the designers of their own vessels — which many private builders are not, we are sorry to say. These the Surveyor and his assistants should have temporarily associated with themselves, and the whole together might have designed the vessels required. No one can doubt that by these means the nation at large would have been better served and better satisfied than by any other. We see enormous difficulties surrounding the matter as it now stands; but as we should only add to the probable embarrassment of the authorities by particularizing them here we refrain from mentioning them more minutely. We confess, however, that even now we see no other mode of both serving and satisfying the public than that we have pointed out. But little time was given for the preparation of the designs—only one month, we believe—and it is therefore scarcely possible that any of them will be so well-digested and complete as to be fit to be taken at once as the model from which the proposed ships are to be built. There will, therefore, probably be a design prepared by the Surveyor of the Navy, embodying any valuable improvements which the competing designs may contain, for which, of course, the designers must be liberally compensated. But we should not think the Surveyor would, under existing circumstances, choose to finally arrange a design without taking personal counsel of the best of the private builders to whom their lordships have appealed. If he should, with half-a-million of money at stake, there will be great room afforded for cavilling both in and out of Parliament.

But however this may be, after careful consideration of the means and appliances of modern naval warfare, we have no hesitation in saying that in avoiding the error which the French Government is committing in building wooden ships of the *Napoleon* or *Agamemnon* class razéed, covering them *completely* with iron—as they must—and driving them with engines of not more than 900-horses power, our own authorities have acted with true wisdom, and in this respect deserve the support of the nation. Nor can we refrain from expressing a certain grim sense of satisfaction in knowing that one effect of spending this half-a-million will be to place the entire navy of France at an undoubted disadvantage. Our faithful and

Digitized by Google

pacific ally has, as is well known, put us to enormous expenses lately by menacing us with continual and rapid additions to his navy. We have him to thank for an expenditure of one million at least during the coming year. There is some sweetness in the quiet revenge which we are about to take. In little more than a year, we shall have two shell-proof frigates, so built that they may act as rams if need be, traversing the channel at the rate of 14 knots an hour. Against these he could not think of bringing the ships to which we have referred. He must, therefore, either accept our superiority with patience, or himself cast about for the means of providing vessels as costly as our own. Is he able to play out the game on which he has entered with so much boldness? For the sake of the tax-payers of both France and England, we hope he will not attempt to proceed with it.

GOVERNMENT SECRETS.

One of the sprightliest of American poets says, "There's nothing we read of in torture's inventions, like a well-meaning dunce, with the best of intentions." We are reminded of the verse just now by a few "dunces" with whom we have lately met, and who profess to feel terrified at the publicity we have given to a description of the wonderful Armstrong Gun. We cannot teach these people what we have long known ourselves, viz., that all pretences to secrecy on the part of our Government in respect of naval or military improvements are mere mockeries. They *will* believe that all the careful guarding, and housing, and locking up of the new weapon, which the *Times* sarcastically tells us of, is really done to keep foreign governments in ignorance of its construction; and they *will* believe that our publication of the facts was traitorous. It is, perhaps, useless to attempt to instruct such "well-meaning dunces," but let us, nevertheless, once more endeavour to enlighten them somewhat. First, then, we beg to inform them that an application for the purchase of a large quantity of a special kind of iron used in the Armstrong Gun was made by an agent of the French Government several days before our article appeared. Would this have been the case if the French Government had been ignorant of the structure of the gun? Again, we wish these timid spirits to know that, when the Government suppressed Sir W. Armstrong's application for a patent, and had his provisional specification carefully sealed up in the Great Seal Patent Office, a copy of that very document was in the hands of certain persons, and had been copied by private clerks, who must therefore have known all about it; and yet no steps were, so far as we can learn, taken to check the escape of the invention through that avenue. Again, the construction of the Armstrong Gun has all along been known, in all its details, to several individuals—not army and navy officers only, who may be supposed incapable of betraying the confidence of the Government—but private persons, who are under no obligation to keep it secret. And, still again, we would request our distressed friends to observe that the armed guard, and the watchful attendants, and the covered shed at Woolwich are manifestly mere blinds to the public, because no person could possibly find out how to produce such a weapon by the mere sight of the finished gun. The chief secrets, on which success almost exclusively depends, lie not in the mere contour of the gun, or the external arrangement of its parts, but in the internal construction, and the manufacturing process, which no mere inquisitive stranger could possibly discover by gazing at it. These Government pretences to secrecy are, we repeat, nothing more than mockeries. And lest any reader should refuse to accept our word in this matter, we will back our assertion by an authority—a very influential and a very modern one. Within a few hours after the appearance of our description of the Armstrong gun, and as if in anticipation of the foolish fears which we are now combating, Sir John Pakington, the First Lord of the Admiralty, in the House of Commons, said, "*Foreign Governments are perfectly well aware of what goes on in this country. If there is any concealment at all, it is a concealment from the people.*" (*Vide* the *Times* for Sat., Feb. 26). Are the sceptics satisfied? We have a word to add, with this declaration from Sir John before us. If Government departments are to practice "concealment" at all, let us visit them with the responsibility of secrecy. If the British public are to be kept in the dark in respect to things of this kind, and peaceable citizens are to be seized by armed soldiers, and to have their property taken from them, simply because they take a pencil sketch of what is there on an open common before them, then, in the name of reason, let us require the Government to keep foreigners also ignorant of such things. It is useless to say they cannot, for if they cannot do the one, what necessity can there be for doing the other? And we have the greater right to ask this, because that "concealment from the people," of which Sir John Pakington speaks, is likely to result in great personal injury. The Armstrong invention may, for example, prove to be an imitation of, or an infringement upon, another man's patented rights. Indeed, in a letter which appears in another column, we are told, now the description of it is made public, that a gun possessing some of its principal features has been repeatedly urged upon the attention of the War Department, and has been lying at Woolwich for years past. And, in addition to this, we know that in the first and only instance in which the English Government ever ventured to suppress a patent—which was in the case of Mr. Macintosh's extraordinary system of warfare proposed during the late Russian War—the inventor was trifled with until the war ended, and then, when the demand for the invention had ceased, had his patent coolly granted him, and has now to seek redress at the hands of Parliament. In these, and in many other ways, great injustice may be done under the secret system. In conclusion, we have to announce that the Government have abandoned the bill which they prepared and proposed introducing into the House of Commons to justify this novel process of sealing up patented inventions. In this they have done well; for unless they can first pass an act for the suppression of the press, an act for the suppression of patent specifications would add but exceedingly little to their present powers of "concealment from the people." Our article on the Armstrong gun has, therefore, had at least the one good effect of preventing the Government from committing an act of folly.

THE ARMSTRONG AND WHITWORTH GUNS.

It needs no prophet to foretell that the promotion, and the high appointment, and the £20,000 awarded to Sir William Armstrong (*vide* General Peel's speech on page 171), will arouse the cupidity and jealousy of many men who believe they have extraordinary claims upon the Government. And for this reason, all who in any way put forward the merits of other improvers of our ordnance will be suspected of being either envious themselves or the organs of the envy of others. But while aware of all this, we refuse to be trammelled by such considerations. Caring for nothing but what is just and right, we shall be daunted by no apprehension of what malevolent men may please to think or say of us. We fearlessly state that we are just now running some risk of exalting the improvements of Sir William Armstrong at the expense or to the injury of others; and as Mr. Whitworth's system very recently excited much public expectation—more recently than any except Sir William's—let us glance at a few facts in connection with it, in order to put ourselves upon our guard in this important matter.

Those who know anything of Mr. Whitworth's plans, must be aware that the mere polygonal form which he gives to the bore of the cannon is by no means the whole of his invention. That form admits, for example, of hard-metal projectiles being employed instead of compound shot, or shot coated with soft metal; and the piece, instead of being necessarily a breech loader, may be loaded at the breech or muzzle as required. Again, the Whitworth projectiles are variously adapted to suit special purposes. For ordinary practice, cast-iron shot, shaped by self-acting machinery so as to fit the hexagonal bore, are used. For firing through water, flat-fronted, or punch-shaped projectiles are employed; and we have been informed on good authority that these flat-fronted projectiles have been fired through thirty feet of water, and after that have retained more than sufficient force to penetrate a ship's bottom! This is a most significant result, and one which promises to be of immense importance in connection with naval armaments. These projectiles, if made of tough hard iron, may also be driven through the thickest wrought iron plates that are made. They were tried last year at Portsmouth, in the presence of an official committee, against the 4-in. wrought iron plates which we are now about to use as a casing for ships' sides. A 68-lb. flat-fronted projectile fired from a distance of 450 yards, perforated both the iron plate and the ship's side on which it was firmly bolted. It punched a huge saucer-shaped piece fairly out of the plate and left a clean hole behind it. As we stated in a former number, the gun from which the shot was fired burst; but this took place on a subsequent day. We were not then aware that the shot had successfully penetrated the plate and the ship's side in the manner explained. And this brings us to another important feature of the case. The gun used on the occasion referred to was an ordinary Government piece, cast solid on the old plan, and was inherently too weak to bear the strain caused by firing a long rifled projectile. But to test the invention fully and fairly, the gun should be constructed throughout on the improved plan of the inventor. The employment of a weak construction was ill-advised and unfortunate, and probably caused blame to be imputed to the system of Mr. Whitworth, when the failure was due to the use of iron cast solid in large masses. The experiment, however, may be considered to have settled two very important questions, and shown—1st, that guns cast on the old plan are inapplicable for rifled cannon; 2nd, that wrought iron plates four inches thick, are *not shot-proof* at a range of at least 450 yards. Mr. Whitworth, in his treatise on rifled arms, reviewed in a late number of the Mechanics' Magazine, makes these remarks:—"In comparing the "strain upon a rifled cannon with that upon a "smooth bore, the work done by the respective "pieces must be taken into consideration. If "the full powers of the former are to be exerted, "and if the extreme ranges which it is capable "of giving are required, a proportionally greater "strain will be put upon the piece on account

Digitized by Google

"of the elongated form of the shot, and more "strength is therefore required. The mode of "making large iron guns, by casting them in "solid masses (as at present) is highly objection-"able, and is certainly not suitable for bearing "the full strain of a rifled gun. It is well known "that if iron be cast in large masses, great ir-"regularities will be produced in the metal "during the process of cooling; and, beyond a "certain limit, little or no increase of strength "is gained by increasing its thickness. Im-"proved modes of construction can, however, "be adopted, which will admit of the gun being "loaded at the breech when required, and will "give all the strength necessary for as large a "charge of powder as can be consumed with the "projectile intended for the piece."—See p. 82.

The concluding observation shows that Mr. WHITWORTH anticipates no difficulty in making his guns of sufficient strength; and it was not to be supposed that he would allow the matter to rest where it is. We were not, therefore, surprised to learn from General PEEL in the House of Commons on Monday last, that Mr. WHITWORTH is renewing his experiments with guns of greater strength. We wish him success in his undertaking.

As we have before said, there is great mechanical promise in his system; and it is a fact, however strange it may appear, that no gun has yet been made in order to test that system thoroughly. Such a gun is now, however, in course of construction, and, notwithstanding the great capabilities of the Armstrong weapon, we shall look anxiously for the trial of the other. We are, we firmly believe, nearer the beginning than the end of ordnance improvements.

ON THE CONSERVATION OF FORCE.

By PROFESSOR FARADAY, D.C.L., F.R.S., &c.

[THE volume of "Experimental Researches in Chemistry and Physics," (Vol. III.) which Professor Faraday has just published, contains the following original article on the Conservation of Force. As we very prominently discussed the previous papers of the author upon this subject, and as his present remarks appear to form a reply in part, at least, to the objections which we brought against those papers, it is incumbent upon us to give place to them.]

"During the year that has passed since the publication of certain views regarding gravitation, &c., I have come to the knowledge of various observations upon them, some adverse, others favourable: these have given me no reason to change my own mode of viewing the subject; but some of them make me think that I have not stated the matter with sufficient precision. The word 'force' is understood by many to mean simply 'the tendency of a body to pass from one place to another,' which is equivalent, I suppose, to the phrase 'mechanical force;' those who so restrain its meaning must have found my argument very obscure. What I mean by the word 'force,' is the *cause* of a physical action; the source or sources of all possible changes amongst the particles or materials of the universe.

"It seems to me that the idea of the conservation of force is absolutely independent of any notion we may form of the nature of force or its varieties, and is as sure and may be as firmly held in the mind, as if we, instead of being very ignorant, understood perfectly every point about the cause of force and the varied effects it can produce. There may be perfectly distinct and separate causes of what are called chemical actions, or electrical actions, or gravitating actions, constituting so many forces; but if the 'conservation of force' is a good and true principle, each of these forces must be subject to it: none can vary in its absolute amount; each must be definite at all times, whether for a particle, or for all the particles in the universe; and the sum also of the three forces must be equally unchangeable. Or, there may be but one cause for these three sets of actions, and in place of three forces we may really have but one, convertible in its manifestations; then the proportions between one set of actions and another, as the chemical and the electrical, may become very variable, so as to be utterly inconsistent with the idea of the conservation of two separate forces (the electrical and the chemical), but perfectly consistent with the conservation of a force, being the common cause of the two or more sets of action.

"It is perfectly true that we cannot always trace a force by its actions, though we admit its conservation. Oxygen and hydrogen may remain mixed for years without showing any signs of chemical activity; they may be made at any given instant to exhibit active results, and then assume a new state, in which again they appear as passive bodies. Now, though we cannot clearly explain what the chemical force is doing, that is to say, what are its effects during the three periods before, at, and after the active combination, and only by very vague assumption can approach to a feeble conception of its respective states, yet we do not suppose the creation of a new portion of force for the active moment of time, or the less believe that the forces belonging to the oxygen and hydrogen exist unchanged in their amount at all these periods, though varying in their results. A part may at the active moment be thrown off as mechanical force, a part as radiant force, a part disposed of we know not how; but believing, by the principle of conservation, that it is not increased or destroyed, our thoughts are directed to search out what at all and every period it is doing, and how it is to be recognised and measured. A problem, founded on the physical truth of nature, *is stated*, and, being stated, is *on the way* to its solution.

"Those who admit the possibility of the common origin of all physical force, and also acknowledge the principle of conservation, apply that principles to the sum total of the force. Though the amount of mechanical force (using habitual language for convenience sake) may remain unchanged and definite in its character for a long time, yet when, as in the collision of two equal inelastic bodies, it appears to be lost, they find it in the form of heat; and whether they admit that heat to be a continual mechanical action (as is most probable), or assume some other idea, as that of electricty, or action of a heat-fluid, still they hold to the principle of conservation by admitting that the sum of force, *i. e.*, of the 'cause of action,' is the same whatever character the effects assume. With them the convertibility of heat, electricity, magnetism, chemical action and motion is a familiar thought; neither can I perceive any reason why they should be led to exclude, *à priori* the cause of gravitation from association with the cause of these other phenomena respectively. All that they are limited by in their various investigations, whatever directions they may take, is the necessity of making no assumption directly contradictory of the conservation of force applied to the sum of all the forces concerned, and to endeavour to discover the different directions in which the various parts of the total force have been exerted.

"Those who admit separate forces inter-unchangeable, have to show that each of these forces is separately subject to the principle of conservation. If gravitation be such a separate force, and yet its power in the action of two particles be supposed to be diminished fourfold by doubling the distance, surely some new action, having true gravitation character, and that alone, ought to appear, for how else can the totality of the force remain unchanged? To define the force 'as a simple attractive force exerted between any two or all the particles of matter, with a strength varying inversely as the square of the distance,' is not to answer the question; nor does it indicate or even assume what are the other complementary results which occur; or allow the supposition that such are necessary: it is simply, as it appears to me, to *deny* the conservation of force.

"As to the gravitating force, I do not presume to say that I have the least idea of what occurs in two particles when their power of mutually approaching each other is changed by their being placed at different distances; but I have a strong conviction, through the influence on my mind of the doctrine of conservation, that there is a change; and that the phenomena resulting from the change will probably appear some day as the result of careful research. If it be said that ''t were to consider too curiously to consider so,' then I must dissent: to refrain to consider would be to ignore the principle of the conservation of force, and to stop the inquiry which it suggests—whereas to admit the proper logical force of the principle in our hypotheses and considerations, and to permit its guidance in a cautious yet courageous course of investigation, may give us power to enlarge the generalities we already possess in respect of heat, motion, electricity, magnetism, &c., to associate gravity with them, and perhaps enable us to know whether the essential force of gravitation (and other attractions) is internal or external as respects the attracted bodies.

"Returning once more to the definition of the gravitating power as '*a simple attractive force exerted between any two or all the particles or masses of matter at every sensible distance, but with a* STRENGTH VARYING *inversely as the square of the distance*,' I ought perhaps to suppose there are many who accept this as a true and sufficient description of the force, and who therefore, in relation to it, deny the principle of conservation. If both are accepted, and are thought to be consistent with each other, it cannot be difficult to add words which shall make 'varying strength' and 'conservation' agree together. It cannot be said that the definition merely applies to the *effects* of gravitation as far as we know them. So understood, it would form no barrier to progress; for that particles at different instances are urged towards each other with a power varying inversely as the square of the distance is a truth: but the definition has not that meaning; and what I object to is the pretence of knowledge which the definition sets up when it assumes to describe, not the partial effects of the force, but the nature of the force as a whole."

CARRIAGES FOR THE KING OF PRUSSIA.

IT can scarcely be otherwise than encouraging to inventors to find that the discoveries of some years past, which, for a time, were altogether adandoned for lack of appreciation, and patents which have almost consigned their then sanguine originators to a lunatic asylum, are now the common-place things of the day. In every circle one or more inventions which suffered discouragement will present themselves either as a prominent necessity, or as having formed an integral portion of that progress which is the characteristic of the present period. We were much struck with these facts upon inspecting the several improvements which the Messrs. Hooper, of the Haymarket, have brought into the science of carriage building, and which they have so successfully arranged into one happy and harmonious whole, in the carriages intended for the King of Prussia. In the building of these equipages there are patent inventions often and twelve years' standing, which, when they were first introduced, had to bear all the opposition and contumely of the trade, yet are now universally acknowledged to be correct in principle, and eminently valuable. The now well known C spring is one of these inventions. Eleven years ago few or none would look at it. It is now in every carriage built for royalty, whether in the luxurious east where "the extremes of motion and of rest are one," or in the not less refined cities of continental Europe. It is thus with patents as with children—they can be made to earn their own, if they be but kept long enough, and there exist intrinsic merit in their composition.

THE THEORY OF NAVAL ARCHITECTURE.

No. V.

THE three rules before enunciated and proved, although sufficiently accurate for the requirements of the naval architect, are the simplest cases of that general method of approximating to a curvilinear area which consists in drawing a parabolic curve so as to coincide with the given curve at a number of points, and taking the area bounded by the parabolic curve as the area required, neglecting the small areas between the curves.

The equation to a continuous parabolic curve, which may always be made to pass through $n+1$ points, is

$$y = A + Bx + Cx^2 + Dx^3 + Ex^4 + \&c. \ldots\ldots + Px^n;$$

and when the points are at the extremities of $n+1$ equidistant ordinates, the area, which is bounded by this curve, the two extreme ordinates, and the line of abscissæ, may be obtained for a large number of values of n. Various mathematicians since Newton—the discoverer of the method—in endeavouring to render the approximations as accurate as possible, have fully examined the subject, and produced numerous formulæ by means of which curvilinear areas may be approximated to.

Atwood in the *Philosophical Transactions* of the Royal Society for the year 1796, has given formulæ for calculating the area corresponding to all numbers of ordinates from 2 to 9 inclusive; and whatever may be the nature of the given bounding curve, the approximating parabolic curve coincides with it at the extremities of all the given ordinates.

The following are these formulæ adapted to the notation we have already made use of:—

No. of Ordinates. *Area.*

2..... $\left(a_1 + a_2\right)\frac{m}{2}$;

3..... $\left(a_1 + a_3 + 4a_2\right)\frac{m}{3}$;

4..... $\left\{ a_1 + a_4 + 3(a_2 + a_3) \right\}\frac{3m}{8}$;

5..... $\left\{ 7(a_1 + a_5) + 32(a_2 + a_4) + 12a_3 \right\}\frac{2m}{45}$;

6..... $\left\{ 19(a_1 + a_6) + 75(a_2 + a_5) + 50(a_3 + a_4) \right\}\frac{5m}{288}$;

7..... $\left\{ 41(a_1 + a_7) + 216(a_2 + a_6) + 27(a_3 + a_5) + 272a_4 \right\}\frac{m}{140}$;

8..... $\left\{ 36779(a_1 + a_8) + 175273(a_2 + a_7) + 64827(a_3 + a_6) + 146461(a_4 + a_5) \right\}\frac{m}{120960}$;

9..... $\left\{ 989(a_1 + a_9) + 5888(a_2 + a_8) - 928(a_3 + a_7) + 10496(a_4 + a_6) - 4540a_5 \right\}\frac{8m}{28350}$.

By an inspection of the above formulæ we perceive that as the number of equidistant ordinates increases, the calculations to obtain the area become more difficult; and although accuracy is the chief point to be considered, simplicity is also very important.

Now, it would appear, at first sight, that if we wished to obtain a curvilinear area, having given the lengths of a number (9, for example) of equidistant ordinates, if we could obtain the area between a continuous parabolic curve which passes through the nine given points at the extremities of the ordinates and the other boundaries of the figure, this area would be a very close approximation to the area required, whatever the given curve might be; and would certainly appear to approximate more nearly to the true area than that obtained by passing four sets of parabolic curves through the extremities of the same number of sets of three consecutive ordinates, and finding the area of which these curves are the boundary—which is done when such an area is found by means of Rule 2.

In order to see whether this is the case or not, and also to show the application of the Rules we have already proved, we will find, by way of example, the area of the quadrant of a circle whose radius is 24 feet; a figure which may be regarded as the half midship section of a vessel, the breadth of which is 48 feet, and draught of water to the lower edge of the rabbet of the keel 24 feet. Let $P_1P_7N_1$ (Fig. 12) represent this half section, and P_1N_1 the load water line. Divide N_1P_7 into six equal portions, each being equal to 4 feet: and through the points of division draw ordinates parallel to P_1N_1; then from the property of the circle,

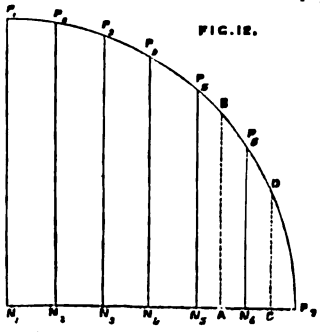

FIG. 12.

$a_1 = P_1N_1 = 24{\cdot}00$;

$a_2 = P_2N_2 = \sqrt{24^2 - 4^2} = 23{\cdot}67$;

$a_3 = P_3N_3 = \sqrt{24^2 - 8^2} = 22{\cdot}63$;

$a_4 = P_4N_4 = \sqrt{24^2 - 12^2} = 20{\cdot}78$;

$a_5 = P_5N_5 = \sqrt{24^2 - 16^2} = 17{\cdot}89$;

$a_6 = P_6N_6 = \sqrt{24^2 - 20^2} = 13{\cdot}26$;

$a_7 = 0$.

The exact area of the quadrant is, we know, equal to

$$\cdot 7854 \times 24^2 = \cdot 7854 \times 576 = 452{\cdot}39 \text{ feet.}$$

But applying the second rule to these ordinates, we have

First and last ordinates.	*Even ordinates.*	*Odd ordinates.*

446·865 Approximation by third rule
452·39 true area

5·525 Difference.

This approximation is not quite so near the true area as that obtained by the second rule: although in this case the curved boundary is composed of portions of only two parabolas, whilst in the other it is composed of portions of three parabolas.

Applying the formula already given when the curve is continuous through the seven points, viz., that opposite seven ordinates in the table, we have

$$\text{Area} = \left\{ 41(a_1 + a_7) + 216(a_2 + a_6) + 27(a_3 + a_5) + 272a_4 \right\}\frac{4}{140};$$

First and last ordinates.	*2nd and 6th ordinates.*	*3rd and 5th ordinates.*	*4th ordinate.*

7 | 15707·08

5 | 2243·87

$\frac{4}{140} = \frac{1}{35} = \frac{1}{7 \times 5}$

448·774 Approximate area.

This gives a result a little nearer the true area than either of the other methods, but perhaps not so near as one might have expected.

We could show that in all these cases the errors arise almost entirely on account of the parabolic curves not coinciding with the circular arc in that part of it near to P_7, whilst they very nearly coincide with it in the part near to P_1: it is evident, therefore, that were the ordinates near to P_7 more numerous, the errors would be diminished, and that even if the ordinates near to P_1 were placed further apart.

To illustrate this:—Let the ordinates drawn at distances 4 feet and 12 feet from P_1N_1 be expunged; and two others be drawn at distances of 18 and 22 feet respectively from P_1N_1. The number of ordinates would still be 7, but there will be three ordinates drawn, between which the common interval is 8 feet; and five ordinates between which the common interval is 2 feet. To each of these cases Rule 2 may be applied.

Digitized by Google

Let AB and CD be drawn at distances of 18 and 22 feet respectively from P_1N_1.

Then $AB = \sqrt{24^2 - 18^2} = 15{\cdot}88$;

$CD = \sqrt{24^2 - 22^2} = 9{\cdot}59$.

The remaining ordinates have already been given. Consequently the area between P_1N_1 and $P_5N_5 = \frac{8}{3}\left\{24{\cdot}00 + 4 \times 22{\cdot}63 + 17{\cdot}89\right\}$; and the area between P_5N_5 and P_7

$$= \frac{2}{3}\left\{17{\cdot}89 + 4(15{\cdot}88 + 9{\cdot}59) + 2(13{\cdot}26)\right\};$$

$$= \frac{8}{3}\left\{\frac{17{\cdot}89}{4} + 15{\cdot}88 + 9{\cdot}59 + \frac{13{\cdot}26}{2}\right\}.$$

Therefore the approximate area of the whole quadrant which is equal to the sum of these

$$= \frac{8}{3}\left\{24{\cdot}00 + 4 \times 22{\cdot}63 + 1\tfrac{1}{4} \times 17{\cdot}89 + 15{\cdot}88 + \frac{13{\cdot}26}{2} + {\cdot}59\right\};$$

or writing them down as below in a form more convenient for calculation, we have,

Ordinates.		*Multipliers.*		
24·00	×	1	=	24·00
22·63	×	4	=	90·52
17·89	×	1¼	=	22·36
15·88	×	1	=	15·88
13·26	×	½	=	6·63
9·59	×	1	=	9·59
·0	×	¼	=	·0
				168·98
				8
				3)1351·84
				450·61 Approximation
				452·39 True area
				1·78 Difference.

This is a close approximation; but as in such a case in practice the ordinates would be more numerous, the result would be still nearer the true area.

The third Rule may also be applied, when the common interval between any sets of four equidistant ordinates varies. In the above example let ordinates be drawn at distances of 6 and 18 feet respectively from P_1N_1; these, with P_1N_1 and P_3N_3, make four equidistant ordinates at 6 feet apart, to which Rule 3 may be applied.

Also, having already given the ordinates drawn at distances of 20, 22, and 24 feet respectively from P_1N_1. These, together with the ordinate 18 feet from P_1N_1, form another set of four equidistant ordinates with a common interval of 2 feet, to which the third Rule may also be applied.

Ordinate at 6 feet from $P_1N_1 = \sqrt{24^2 - 6^2} = 23{\cdot}24$,

" 18 " $= \sqrt{24^2 - 18^2} = 15{\cdot}88$.

Therefore area between P_1N_1 and the ordinate at 18 feet from it $=$

$$\frac{3 \times 6}{8}\left\{24{\cdot}00 + 3(23{\cdot}24 + 20{\cdot}78) + 15{\cdot}88\right\};$$

Area between the above and P_7

$$= \frac{3 \times 2}{8}\left\{15{\cdot}88 + 3(13{\cdot}26 + 9{\cdot}59) + 0\right\}$$

$$= \frac{18}{8}\left\{\frac{15{\cdot}88}{3} + 13{\cdot}26 + 9{\cdot}59 + 0\right\}.$$

And the whole area, or the approximation to the area of the quadrant, is equal to the sum of these, or

$$= \frac{9}{4}\left\{24{\cdot}00 + 3(23{\cdot}24 + 20{\cdot}78) + 1\tfrac{1}{3} \times 15{\cdot}88 + 13{\cdot}26 + 9{\cdot}59 + 0\right\}.$$

Putting this expression in a form convenient for calculation,

Ordinates.		*Multipliers.*		
24·00	×	1	=	24·00
23·24	×	3	=	69·72
20·78	×	3	=	62·34
15·88	×	1⅓	=	21·17
13·26	×	1	=	13·26
9·59	×	1	=	9·59
0·0	×	⅓	=	0·0
				200·08
				9
				4)1800·72
				450·18 Approximation.

It appears, then, that the *second* and *third* Rules may be made to yield very close approximations to curvilinear areas if due care be taken to fix the positions of the ordinates with reference to the curvature; making the common interval between the ordinates smallest at that part of the curve which has the greatest amount of curvature between two ordinates; or where the variation of the directions of the curve at the extremities of consecutive ordinates is greatest.

And lest it should appear that one example is insufficient to show the general superiority of the second and third Rules, when the common interval is made to vary in some of the sets of ordinates, we will take one more example, and then leave the student to work out others for himself.

THE TONNAGE LAWS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Woolwich Dockyard, 7th March, 1859.

GENTLEMEN,—With reference to your editorial article on the "Tonnage Laws" in the MECHANICS' MAGAZINE of the 25th ult., No. 9, I feel myself called upon to offer a few remarks. You say—

"The main ingredient of the report (Report of the late Committee consisting of Messrs. Fairbairn, Atherton, Henderson, and Wright, on Shipping Statistics, presented to the British Association at Leeds, 1858,) is a laudation of the *Bremen*, and by the adoption of this report the British Association for the advancement of Science have really converted themselves into advertisers of the *Bremen* and all concerned in her construction, her engines, and her navigation."

I beg to state that the constructors of the *Bremen*, Messrs. Caird and Co., engineers and shipbuilders of Greenock, had nothing whatever to do with that vessel being referred to in the report, which was presented by Messrs. Fairbairn, Atherton, Henderson, and Wright, to the British Association at Leeds, in 1858, excepting that they complied with the request of the Committee. The *Bremen* was selected by the Committee to exemplify the system set forth in the report, whereby,

"The owners and charterers of ships, and the directors of shipping companies or agents by whom shipping affairs are conducted, should themselves have the means of ascertaining the relative dynamic merits and working condition of their ships, without any reference whatever to the professional assistance of builders or of engineers, but be enabled to judge for themselves whether the performance be good or bad by reference the data afforded by their counting-house records."

The *Bremen* was so selected, not because she was the production of any particular constructor, but as being the vessel which gave the highest co-efficient of dynamic performance of any vessel brought before the notice of the committee, and of which the statistical data of construction, including scale of displacement and scale of vertical sections, were also given in a complete form, and with permission to make the same public, as set forth in the report. Let me ask, What would have been said had our report been based on the asserted performance of a nameless vessel?

The animus of your editorial article is apparent. For my own part, I confidently, and without retracting one word, leave the report and the statistical statements set forth in the appendix as published in the journal of the Society of Arts on the 7th of January last, but not published in the MECHANICS' MAGAZINE, to the judgment of all who have paid any attention to the deficiencies of our present system of shipping registration.

It is only by the agency of publicity that any public abuse can be exposed and rectified. I maintain that there is no abuse of public interests greater in respect of its pecuniary magnitude, nor more insidious in respect of its character, than that which emanates from the deficiencies of our present system of shipping, shipping registration, and of shipping denomination called "Tonnage;" but I am confident in the hope that the great battering ram "Truth," if perseveringly worked, will shake to its foundations any combination of ribaldry and special-pleading delusion within which such abuses may be protected or take refuge. I confidently anticipate that the opportunities which have been afforded by the Society of Arts, London, on various occasions, and by the British Association at Cheltenham, Dublin, and Leeds, for putting this battering ram into operation, will eventually, in this matter of shipping registration, add another very important item to the list of services which these Institutions have rendered in the cause of public good.

I am, Gentlemen, your very obedient servant,

CHARLES ATHERTON.

[We do not like to refuse Mr. Atherton space for the above letter, but we think it unfair in him to address such a letter to us. We said nothing in the article to which Mr. Atherton refers that can be supposed to impute undue partiality to Messrs. Caird and Co., on the part of himself or his friends. On the contrary, we expressly noticed the prominence given to the *Bremen*, as strongly illustrating "the mischievous effects of the proposed action of the committee." Such effects are inseparable from the method of proceeding adopted by the committee. Where, then, is the "animus" which Mr. Atherton imputes to us? We are quite content to combat the arguments of Mr. Atherton; and we have neither the occasion nor the desire to import any charges of a personal nature into the discussion. We hope that Mr. Atherton will respect himself too much to do so. We entertain more respect for him than for another member or two of the British Association Committee; and we hope if that Committee is to grovel in personal altercations, he will, at least, keep himself above them. EDS. *M. M.*]

SUFFIELD'S MARINE ENGINE-ROOM TELEGRAPH.

ONE of these most useful and essential machines for communicating from the captain to the engineer in steam-ships, has recently been fitted (by the command of the Lords of the Admiralty) on board H.M.S. *Cressy*, to be tried in competition with others, as we have previously stated. The machines have lately been put through a series of severe proofs, under the direction and management of Captain Halsted, of the steam reserve at Sheerness. The results of the experiments with Suffield's telegraph, whilst the ship was lying at anchor, proved so eminently satisfactory as to induce Captain Halsted to take the ship to sea on Friday last. Captain Halsted worked the telegraph himself the whole of the day, and put it through the most severe tests, but the instrument proved completely successful, and will no doubt be reported upon accordingly to the Lords of the Admiralty,

GREENWOOD'S IMPROVED STEAM BOILERS.

MR. JOHN GREENWOOD, of Rawdon, Yorkshire, has just patented an invention designed to supply a very great heating surface in steam boilers. For this purpose he forms the plates of the flues, or other heating surfaces of boilers, or of other apparatus for heating water, of plates with deep undulations, except at the parts where the separate plates are connected together, or to the angle iron by which they are held together; and he prefers that these undulations in the plates shall be of such an extent as to double the heating surface. He also forms the flue spaces of a deep undulatory form, in addition to the plates being of the undulating character referred to. Such undulating surfaces are also applicable when forming surfaces for the superheating of steam, or the heating of air. Fig. 1 of the accompanying engravings shows a plan, and Fig. 2, a vertical sec-

FIG. 1.

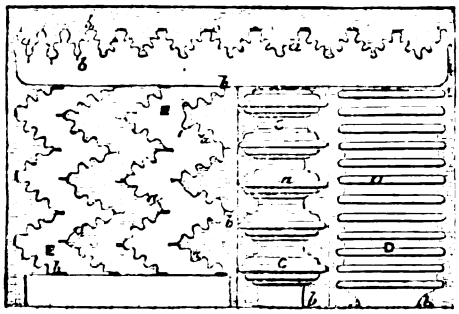

FIG. 2

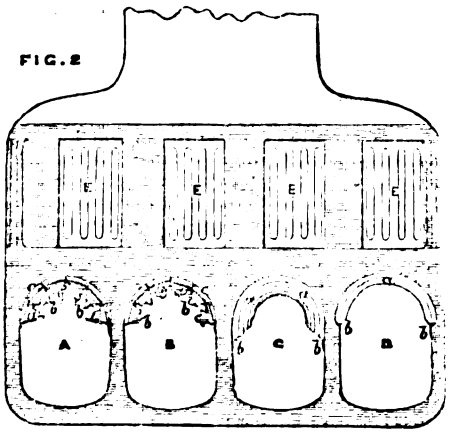

tion in section of a boiler, with his improvements in different forms applied thereto. In Fig. 2, *A* and *B* show two furnaces of the boiler, with the upper or roof plates *a*, *a* thereof combined at *b*, *b*, so as to be of an undulatory character apart from the undulations of which each plate is composed; *c*, *c*, are stays, placed at intervals for giving steadiness to the parts. In the illustrations *C* and *D* (the variations of which are better seen by the plan view, Fig. 1) the undulations run in the direction of the length of the furnace; *E*, *E* are the flue spaces, formed undulatory, as shown in their general character, in addition to each undulation being composed of a series of smaller undulations.

THE BOMBAY WATERWORKS.—The following note needs no introduction:—"Gentlemen:—Our attention having been called to your able article in No. 7, February 11th, on the 'Bombay Waterworks,' we would add that the self-closing public conduits therein mentioned, as well as the slide valves up to 12 inches diameter, were manufactured by us, and that the conduits and valves are the patented inventions of our manager, Mr. Underhay.—CHARLES BOTTON and SON."

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, MARCH 3.

HOUSE OF COMMONS.

CIVIL SERVICE SUPERANNUATIONS.

Sir H. WILLOUGHBY asked what number of persons in the civil service (whether their remuneration be computed by day pay, weekly wages, or annual salary,) will be entitled to superannuation allowance, and at what charge to the public, under clause 2 of the Superannuation Bill.

Sir S. NORTHCOTE said the preparation of such a document would require a considerable time; but he hoped, in the committee, to lay down such general rules as would prove satisfactory.

THE WESTMINSTER CLOCK.

Mr. HANKEY asked whether the bells are now all fixed in the clock tower, whether the works of the clock have also been placed there, and when the clock will be in working order.

Lord J. MANNERS, in reply, read extracts from letters he had received from Sir C. Barry and Mr. E. B. Denison. Sir C. Barry stated that "the bells of the great clock were hoisted as soon as they were approved by the referees, and have been fixed more than three months." Mr. E. B. Denison said "the bells have been fixed in the clock tower; but they are now let down a little, to enable some pieces to be put into the frame (diagonal braces) to strengthen it. The clock is not fixed because the clock-room will not be ready for it until the weight-shaft is properly covered over, and the pendulum-room constructed in it, and an enclosed passage made through the air-shaft to give access from the clock-room to the west dial works. This must also be made of iron, because the air-shaft is, in fact, a chimney; and it must be made carefully, so as to be air-tight, or else the fumes of the ventilating fire will come into the clock-room. The clock-room will be ready for the clock in a week, and the bell-frame will be finished very soon, and therefore the clock should be driving the hands and striking in a few months."

THE NEW FOREIGN-OFFICE.

Mr. CONINGHAM asked when it was intended to exhibit the designs for the new Foreign-office.

Lord J. MANNERS said they would be exhibited as soon as the working drawings and the estimates of the expense of the new Foreign-office were completed. No vote of money would be taken till then.

COLONIAL AND FOREIGN WOOD.

Mr. MITCHELL drew attention to the very anomalous state of the duties on wood, and moved "That it is the opinion of this House that the duties on foreign and colonial wood should be repealed."

Mr. FENWICK seconded the resolution. For his part, representing Sunderland, which was very much interested in the question, he looked upon the tax as being not only, abstractly speaking, unjust, but practically injurious.

Sir S. NORTHCOTE said, under all the circumstances, he contended that no such strong case had been made out as to justify the duties on wood being treated in an exceptional manner, and made the subject of a special resolution condemning the tax. Besides, it was inexpedient, under ordinary circumstances, to anticipate by a resolution of that kind the financial statement of the Chancellor of the Exchequer.

Mr. WILSON said he would never vote for their repeal on the motion of an independent member, apart from considerations arising out of the financial state of the country.

Mr. HUDSON spoke against the duties.

Mr. LABOUCHERE would wish to see the duties repealed. He should not, however, vote for an abstract resolution pledging the House to the repeal of a tax until he had heard the financial statement.

Lord HARRY VANE suggested an alteration in the terms of the motion.

Mr. MITCHELL adopted the suggestion. The motion then stood thus:—"That it is the opinion of this House that the duties on foreign and colonial wood should be repealed as soon as the state of the revenue admits of it."

The CHANCELLOR of the EXCHEQUER: The addition to the motion renders it much more objectionable. I should be happy myself to put an end to this tax, but at present I am not in a position to hold out any hope of the kind. In a month hence, I shall call the attention of the House to the financial state of the country, and it will be open to those who represent the timber trade, or who are in favour of the abolition of this tax, to bring the subject before the House, when, no doubt, it will receive a fair consideration.

The House divided on the amended motion.

For the motion	77	
Against it	133	
Majority		—56

The motion was therefore lost.

FRIDAY, MARCH 4.

HOUSE OF LORDS.

REMOVAL OF THE ROYAL ACADEMY.

Lord LYNDHURST called the attention of the House to the Royal Academy, to the proposal to remove the establishment from the National Gallery to a new situation, and to the conditions of such removal. After an historical review of the Academy, he said the object of the academicians is, and always has been, to remain solely under the control and supervision of the Crown, and therefore they will accept the Government grant upon the condition that they on their part shall be allowed to expend an amount equal to the value of the site in the construction of buildings necessary for the Academy, to be permanently applied for the purposes of art. Thus the grant from the nation will be paid for by that equivalent, because both the land and the buildings to be erected upon it are to be devoted in perpetuity to a great public object.

The EARL of DERBY stated that the extent of the National Gallery is 13,000 square feet, while the superficial area of Burlington-house and grounds is 143,000 feet, or nearly eleven times as much. There are numerous claims on this valuable site, and engagements have been entered into for portions. I have here a list of societies which have received promises of that nature. They are the Royal Academy, the Patent-office, the London University, the Royal Society, the Linnæan Society, and the Chymical Society. But, besides these, the Astronomical, the Geological, the Antiquarian, the Ethnological, the Asiatic, and the Water Colours Societies, which are now located in Somerset-house, are claimants for accommodation in Burlington-house, while strong recommendations have been made to the Government for allotting a portion of the site to the Geographical and Statistical Societies. It is difficult to meet those various conflicting claims; but the principle on which the arrangement with the Royal Academy is to be carried out has been entirely agreed upon, the settlement of details being left as a matter for future consideration between it and the Government. The proposition made to them was that a considerable portion of the site of Burlington-house should be appropriated to their use, and should remain over to them in fee simple, upon condition that upon that site they should erect a building adapted to the purposes of the Academy, and not in its style and character incongruous with other buildings which may hereafter be erected in the same locality. I understand they desire to have half of the entire frontage of the present building facing Piccadilly, and also a large portion of one of its sides. That application for no less than half of a site occupying 143,000 square feet is one of rather an extensive character. Her Majesty's Ministers have deemed it right to ascertain, in the first instance, what amount of space the Royal Academy may reasonably be supposed to want, and, in the next place, before they allot them so large a portion of ground, to be assured that the amount of their funds is such as would enable them to cover, either now or at some future time, with buildings adapted to the objects of the institution, the whole of the site which they require. Her Majesty's Government are disposed to deal with them with the utmost favour and liberality.

Earl Stanhope said the Society of Antiquaries had no intention to make any claim upon the ground at Burlington-house.

SUBMARINE TELEGRAPHS.

Lord WODEHOUSE and other members made some remarks on telegraphs to the East, and in reply,

The EARL of DERBY said that, as to the Atlantic Telegraph Company, the Government had insisted as a first condition in the negotiations now pending that the monopoly of the company should be abolished, and that the Government should be at liberty to assist any company which might be disposed to undertake to lay down other lines. The principle adopted was to repudiate any monopoly, and to hold the Government free to agree with any other company if they should think it desirable to do so.

HOUSE OF COMMONS.

TENDERS FOR MARINE ENGINES.

Mr. H. G. LANGTON asked whether, as Government had thought it necessary to apply for tenders for the supply of marine engines from Liverpool, Scotland, and most of the eminent houses engaged in this particular business, Bristol was included among the places to which invitations for tenders had been made.

Sir J. PAKINGTON said the Government had no wish to exclude any locality from tendering.

THE NAVY.

Sir C. NAPIER moved that, as the First Lord of the Admiralty had stated that the coastguard ships are comparatively useless, the time had arrived when they ought to be replaced by efficient ships. He said the nine blockships, described by the right hon. baronet as comparatively useless, and now stationed at different ports on the coastguard service, were considered by merchant seamen as a disgrace to the country; they ought to be removed and their place supplied by efficient ships; this could be done with great ease.

Sir JOHN PAKINGTON said, I think the gallant admiral rather overstates what fell from me with regard to the blockships. What I stated was, that as line-of-battle ships, as sea-going men-of-war, they are useless ships; but they are by no means useless as floating batteries. They are very powerfully armed, and in the event of England's being engaged in any naval war, these ships, defective as they undoubtedly are, would be found extremely valuable as floating batteries for the protection of our harbours. I am, however, quite ready to admit that I do very much wish that, even for their present purpose, I could see these ships succeeded by more effective and more useful ones. But I must ask the gallant admiral to make some little allowance for the shortness of the time during which I have had to deal with these matters. It is the intention of the present Board of Admiralty that, at all events as the commissions of these ships expire, they should be replaced by stronger and more effective ships. At the same time I cannot think it is expedient simultaneously to exchange all these blockships for larger men-of-war. In the first place, looking to the wear and tear to which they are exposed, I was unwilling to expose one-third of our effective ships to such deterioration. By the end of the present year our line-of-battle ships will be nearly 80 per cent. stronger than I found them, and I shall then be more at liberty to deal with matters of this kind. Great expense would also attend the paying off and throwing out of commission nine ships of this class, and commissioning other ships in their places. Again, we cannot effect such an exchange without making a very considerable demand upon the labour of our dockyards, and I should be unwilling to throw it upon them merely to substitute—for that is all that I should have it in my power to do—screw 80's for these blockships.

Lord PALMERSTON: I think the right hon. baronet has

Digitized by Google

overstated the difficulty of exchanging the one class of ships for the other. The only thing likely to happen is that a superior squadron should appear in the Channel, and that we should not have a fleet of equal force capable of taking the sea immediately and acting its part in the usual manner of naval engagements. For such a purpose the block-ships are useless, and therefore I would impress the expediency of accelerating the substitution of the one class of ships for the other.

Mr. CORRY remarked that the only ships which could be substituted for the steam guard-ships were the 80-gun ships, for nobody would think of putting our three-deckers to do outpost duty along the coast. Now, the 80-gun ships were all, with one exception, in the second-class steam reserve, and it would be necessary to mast and rig them before sending them to sea. The expense of fitting them out would amount to £144,000.

Mr. HORSMAN said, a heavy responsibility would fall on any Government or Board of Admiralty that delayed one single day to strain an effort to place the country once more in a state of maritime security. Let the House consider the mischiefs of an interruption to our commerce and manufactures by the command of the Channel by any other naval power for two or three months. He would ask them whether any expense necessary for the improvement of the navy was not a mere trifle compared with the enormous consequences which would follow such an event as he had alluded to.

Mr. H. BARING hoped the right hon. gentleman would reconsider his dilatory promise as to the block-ships.

Admiral WALCOT hoped the First Lord would direct his attention to getting the ships now in the dockyards finished off as soon as possible. It was essential that the House should, before sanctioning any further expenditure for ships, be satisfied that the Admiralty would build ships on a plan that would ensure speed.

The House then divided on Sir C. Napier's amendment—the numbers were,—

Ayes	74
Noes	37
Majority against the amendment ...	—37

The Speaker then left the chair, and the House went into committee of supply.

THE ARMSTRONG GUN.

General PEEL, in moving the Army Estimates, after dealing with general questions, said:—There was one feature of which the House had heard a great deal—he meant the introduction of Sir William Armstrong's gun. It was impossible for any one to predict what would be the result of the general introduction of that weapon into our army. In the course of the summer he appointed a committee to examine and report upon the different sorts of rifled ordnance which had been submitted to the Government. The report of that committee was entirely favourable to Sir William Armstrong's invention. The gun submitted to the Government by that gentleman was a breech-loading, rifled, wrought-iron gun, of peculiar manufacture, throwing a projectile which answered as either solid or hollow shot, as shell, or as common case. This projectile could also be modified so as to be used by naval batteries and on board ships, and to have a very great explosive effect. The gun had great durability, he having himself seen one which had been fired 1,300 times without the smallest injurious effect being produced upon it. The great advantages of this gun were its extreme lightness, the extent of its range, and its accuracy. An Armstrong gun throwing a projectile of 18lb. weighed one-third as much as the guns now in use discharging shot of that weight. The range of a 32lb. gun, fired with a charge of 5lb. of powder, was a little more than five miles and a quarter, while the precision of the gun was still more extraordinary. The accuracy of the Armstrong gun at 3,000 yards was as seven to one compared with that of the common gun at 1,000 yards; while at 1,000 yards it would hit an object every time which was struck by the common gun only once in 57 times; therefore at equal distances the Armstrong gun was 57 times as accurate as our common artillery. Its destructive effect, also, exceeded anything which had hitherto been witnessed. The carriages had been very much improved, and their introduction into the navy would greatly diminish the number of men required to work the guns. Having ascertained the superiority of the gun, the Government could have no hesitation in at once doing everything in their power to make themselves masters of it. Great as had been the ingenuity and talent displayed by Sir W. Armstrong in regard to this invention, they were exceeded by the liberality with which he at once presented to the Government the patent, for which they must have paid almost any sum of money which he liked to demand. He made no stipulations, and when his noble friend at the head of the Government asked him (General Peel) to think of some sum which might be presented to Mr. Armstrong, he was at once relieved from all difficulty by that gentleman proposing to accept a sum of £20,000 spread over 10 years, which should secure to the country his services as consulting engineer of rifled ordnance. For himself, as he had said, he made no stipulations, but for the firm to which he then, but no longer belonged, he made this arrangement, that if they erected extensive buildings for the manufacture of these guns, and did not receive sufficient orders to cover their expenditure, an arbitrator, who should be the Attorney-General of the day, should decide what compensation they should receive from the Government for the capital which they had laid out. He was convinced that the House would be of opinion that nothing could be more liberal than the manner in which Sir W. Armstrong had dealt with the Government; and would think that he well deserved the honour which, by her own special and personal desire, had been conferred upon him by Her Majesty. The manufacture of some of the larger of these guns was now being proceeded with by Sir W. Armstrong's late partners; it was also the intention of the Government to make some of them at Woolwich under the direction of that gentleman, and when they had got some of the largest size they would be tried against masonry and earthwork, till which was done it was impossible to say exactly what effect they would produce upon fortifications. One thing he might predict, and that was, that sooner or later they would supersede the whole existing armament of the country. He was afraid that the hon. member for Lambeth must make up his mind to a large expenditure on that account; but he was sure that he would not grudge any money the expenditure of which would be for the benefit of the country.

Mr. SIDNEY HERBERT thought the Government deserve the utmost credit for their immediate adoption of this unequalled invention. There are persons who say that to embark in a large outlay for introducing a weapon which is likely to be in a short time superseded by something better is impolitic. My answer is, "Nations cannot afford to wait in the hope of securing this something better of which you speak." The late Emperor Nicholas entertained, I believe, the idea that some invention would soon be brought to light in the scientific world by which railways would be completely superseded, and delayed in consequence the construction of those useful works. But in the meantime he lost Sebastopol, owing to the want of a railroad to connect it with Moscow. I have heard it stated that however admirable for military purposes Armstrong's gun may be, there is some doubt as to its efficiency in naval warfare. The ground upon which that doubt is based is, that a narrow bullet projected with the greatest velocity is that which does least injury to a ship. It passes through, making but a small hole, raises few splinters, and kills a comparatively trifling number of men; while a shot of large calibre, and whose rate of velocity is slower, does infinitely greater damage. The point was one on which scientific men alone can form a sound judgment, but it is, I think, one well worthy of attention when the applicability of Armstrong's gun to sea as well as to land service is to be considered.

Sir J. TRELAWNEY said this gun might revolutionize the whole art of war, and it would be very undesirable to incur an expenditure upon fortifications which might turn out wholly useless.

General CODRINGTON rejoiced to hear that energetic measures would be adopted for introducing the Armstrong gun into the service. England should have at her command, at whatever cost, the most destructive warlike weapons that could be invented. Paradoxical as it might sound, the introduction of such a weapon as the Armstrong gun would tend to diminish the destruction of life, for the greater the range of our guns the less necessary was it to expose the lives of our soldiers.

General DE LACY EVANS said he admired the disinterested patriotism of Sir W. Armstrong in making over unconditionally his admirable invention, commended strongly the adoption by the Government of this great improvement, by ordering the immediate construction of as many of these cannon as could possibly be obtained, and then gave his opinion that the Government was quite right in entirely disregarding the possible contingency of subsequent improvements being proposed.

MONDAY, MARCH 7.

HOUSE OF COMMONS.

HIGHWAYS BILL.

Mr. T. S. DUNCOMBE said he hoped the Under-Secretary of State for the Home Department would consent to let this bill go through committee *pro formâ*, with the view of having the numerous amendments, of which notice had been given, embodied in the Bill.

Mr. HARDY said the Bill had been already postponed for three weeks. The amendments were but trifling, and he hoped the House would allow the Bill to proceed without further delay.

DOCKYARD OPERATIONS.

In the Committee of Supply, Sir J. PAKINGTON asked for a vote of £12,000, which he brought forward in consequence of the strong recommendation from the Surveyor of the Navy that additional shipwrights and other labourers should be engaged in the dockyards during the present month, with a view to the increase of the navy.

The vote was agreed to.

ORDNANCE.—THE ARMSTRONG GUN.—THE WHITWORTH GUN AND RIFLE.—FORTIFICATIONS.

In the same Committee, Mr. MACARTNEY asked what amount of iron ordnance the gun factory at Woolwich was able to turn out in the year.

General PEEL said nothing could be going on more satisfactorily than the gun factory at Woolwich.

Sir C. NAPIER inquired how many Armstrong guns were ready for delivery.

General PEEL replied very few, but a considerable number were in process of manufacture. Machinery was being prepared for turning out as many as possible during the next year, and the government were establishing a factory at Woolwich as well as in the north.

Mr. R. N. PHILIPS asked whether it was intended to vote any money for Mr. Whitworth.

General PEEL replied that the Whitworth gun was tried at the same time and by the same committee as the Armstrong. There was certainly some defect in it then, for it burst; but he believed that Mr. Whitworth had made some improvements in it since. That gentleman had requested that his invention should again be submitted to the committee, and it would assuredly have a fair trial.

General CODRINGTON said it was due to Mr. Whitworth, one of the most eminent mechanicians in this country, to mention that he had given his time and talents freely and without remuneration to the improvement of the rifle. Important as Sir W. Armstrong's cannon was, yet the perfection of the rifle was a matter equally important.

Mr. MONSELL asked whether the Government intended to proceed with fortifications without considering the probable effect of Sir W. Armstrong's wonderful invention upon the present system.

Sir F. SMITH had no doubt that the penetration of Sir W. Armstrong's guns was much more considerable than that of the old ordnance, but the effect upon field-works would probably only be, that instead of making the parapet 18 feet thick, it must be made 20 feet or 22 feet thick. But there were other questions involved.

Lord PALMERSTON trusted the Government would not suspend those works for the immediate defence of Portsmouth and Plymouth which had been thought necessary. Sir W. Armstrong's guns were not yet in use.

General PEEL said, the first thing he did when the merits of Sir W. Armstrong's gun were reported to him was to appoint a committee, including some naval officers, to consider what effect this gun would have upon the system of fortifications. Experiments were now going on. The largest gun hitherto made upon Sir W. Armstrong's plan was a 32-pounder, but Sir W. Armstrong proposed to make cannons of much larger calibre, longer range, and greater weight of projectile.

TUESDAY, MARCH 8.

HOUSE OF COMMONS.

ATLANTIC TELEGRAPH COMPANY.

The CHANCELLOR of the EXCHEQUER, in answer to Mr. Berkeley, said, it is not the intention of the Government to grant any exclusive privilege to any telegraph company.

ENFIELD ESTABLISHMENT.

In answer to Mr. Newdegate,

General PEEL said that a balance sheet, showing the total cost and total production of the Enfield establishment from the period of reconstruction in 1854, had been prepared.

COMBINATION OF WORKMEN.

Mr. DRUMMOND obtained leave to bring in a Bill to amend and explain an Act of the sixth year of the reign of King George IV., to repeal the laws relating to the combinations of workmen, and make other provisions in lieu thereof.

The Bill was brought in and read a first time.

EXTRAORDINARY TIMBER.—At the meeting of the Institute of Civil Engineers, Feb. 22, some specimens of timber recently imported from the North West Coast of America, were exhibited by Mr. G. R. Burnell. It was observed that the quality and dimensions of this timber, which came from near Vancouver's Island and the district bordering upon British Columbia and California, appeared to be such as to justify rather more than the passing notices hitherto given in the technical journals of the metropolis. There were now lying in the Commercial Docks between fifty and sixty logs of this timber, upwards of 100 feet in length, and measuring at least 22 inches on a side. There was one log in particular, which was 129 feet long, die square, perfectly straight and sound, apparently free from dead knots or shakes, and measuring 39¼ inches on the side at the middle of its length. At the butt end it was nearly 4 feet square; and at the taper end it was about 2 feet 4 inches square; and it contained 1,302 cubic feet, or upwards of twenty-six loads. No experiments had been made on the specific gravity, or on the strength of this timber; but from the manner in which it floated, it would appear that its specific gravity was about the same as that of yellow pine. The strength would appear to be equal to that of the best crown memel, if an opinion might be formed from the way in which some planks had been bent, and the conditions of elasticity indicated under such circumstances. For bridge-building, roofing, and scaffolding purposes, it was suggested that this North Western American fir would be of great value, on account of its length, and its remarkably uniform character. Some light spars of the same kind of wood, about 119 feet long and 15 inches diameter at the butt end, had also been imported from the same coast. The price of the very long spars was, at present, about six shillings per foot cubic; this was high, but no doubt it would hereafter be diminished. The price of ordinary lengths was nearly the same per foot cube as that of the best crown memel deals. Attention was directed to the number and closeness of the annular rings, which indicated that the trees were of slow growth; and it was thence inferred that the wood would probably be durable. It was suggested that it would be desirable to make some experiments of an authentic character on the properties of this timber.

GEOLOGISTS' ASSOCIATION.—Rooms have been taken for this association at 5 Cavendish Square, which will be open every Monday for members. The meeting for reading papers is the second Monday. There were thirty candidates for ballot at the last meeting.

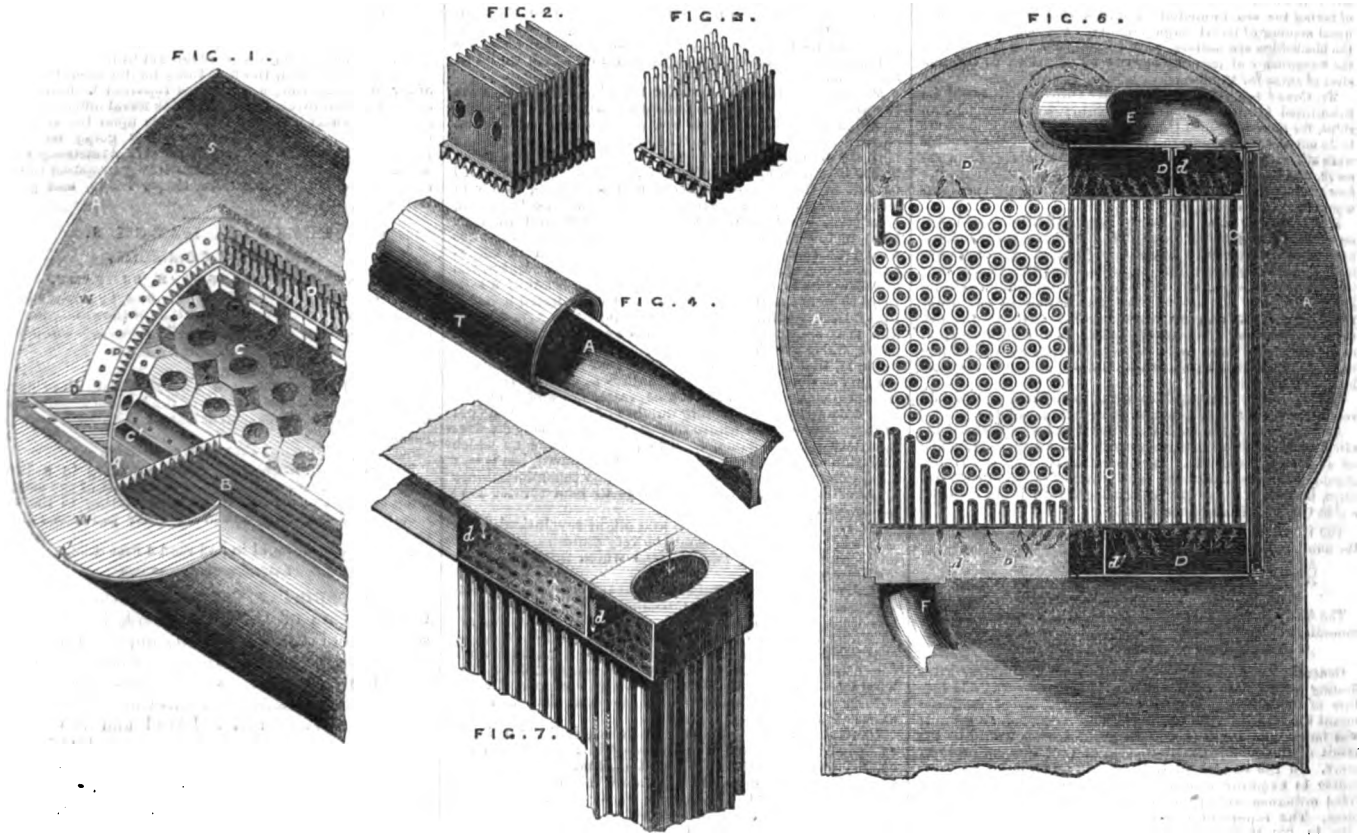
CONYBEARE'S PATENT APPARATUS FOR GENERATING, SUPERHEATING, AND CONDENSING STEAM.

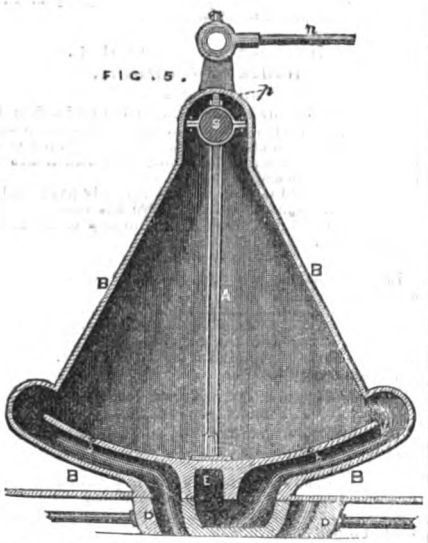


CONYBEARE'S PATENT APPARATUS FOR GENERATING, SUPERHEATING, AND CONDENSING STEAM.

Mr. H. Conybeare, C.E., has recently completed a patent for various improvements in apparatus for effecting the above object.

His invention consists, first, in the employment of removable heat-extractors and removable heat-distributors, whereby he increases the area and augments the efficiency, both of the heat-receiving and of the steam-generating surfaces of the boiler, without interrupting the continuity of the boiler plate, and thereby occasioning weakness and liability to leakage, and without obstructing the action of the scraper employed in cleaning the interior of the boiler of deposit. These heat-extractors consist of cellular or honeycombed surfaces of fire-brick or other suitable material, placed in immediate contact with the interior surface of the fire box or flues. The interior surfaces of the cells act as a continuation and extension of the metallic heat-extracting surface of the boiler in extracting caloric from the flame and heated products of combustion, and conducting and transmitting it to the boiler water. Where the flues are tubes of too small diameter to admit of the cellular lining of fire-brick above described, he arranges the heat-extractors so that the principal mass occupies the centre of the tubes, and is kept in its position by three or more projecting feathers —arranged like the feathers on an arrow—thus dividing the airway of the tubes into two, three, or more divisions, and thereby proportionately increasing the heat-extracting surface exposed to the escaping products of combustion. His removable heat-distributors he places in the interior of the boiler, and resting on and in immediate contact with the inverted surface of the metallic plate separating the boiler water from the furnace and the flues. These removable heat-distributors are made of metal or other suitable material, and so formed as to present a large heat-distributing surface to the boiler water without opposing any obstacle to the free circulation thereof.

Mr. Conybeare describes the following as the



best method with which he is acquainted of carrying this part of his invention into effect:—

Fig. 1 of the accompanying engravings is an isometrical perspective view of part of a furnace fitted with his improved heat-extractors and heat-distributors. This view is supposed to be taken from a point in front of and below the fire-bars, the under-sides only of which are seen. *A* is the inner, and *A'* is the outer shell of the boiler. *W* is the water, and *S* the steam space. *B B* are the fire-bars; *C C* the cellular or honey-comb heat extractors; and *D D* the heat distributors, several of which are shown separately in Fig. 2. These distributors are formed of a sole plate, from which rises a series of parallel leaves of metal as shown, which will offer no obstruction to the free circulation of the boiler water. Fig. 3 illustrates another mode in which they may be formed with advantage. Here they consist of a sole plate, from which rises a series of spikes or rods. The heat extractors are perforated both longitudinally and laterally, as shown, in order to allow the heat to penetrate them thoroughly and with facility. They are supported as shown at *C'*, Fig. 1. The heat-distributors, when formed as in Fig. 2, are likewise perforated to increase the facility with which the heat escapes from them to the water. They are supported as shown at *D'*, Fig. 1. In Fig. 4 is represented a view of the form of heat extractors which he applies to the tubes when the flues are too small to admit of the extractors before described. The heat-extractor *A* here has a turn in it, in order that the hot gases as they pass along through the tube T may be brought constantly into contact with the extractor.

Secondly:—The invention consists in the employment of improved forms of blowers, which he terms the quadrant and disc blowers, for providing the combustion chamber and flues above-mentioned with the amount of air required to perfect combustion, and thus enable the heat-extractors and heat-distributors to do their work in increasing the evaporative efficiency of the fuel employed.

His improved quadrant blower is illustrated in the transverse sectional view, Fig. 5. *A* is the piston, which is caused to vibrate about the shaft *S* by means of a rod *a*, leading from any suitable moving part of an engine, or otherwise, its vibrations being by preference synchronous with those of the engine. *B* is the casing, and *C* a fixed internal plate along which the packing of the piston moves. The piston is also packed above at the point *p*. *D* is a slide valve for alternately cutting off and establishing communication between the escape or blowing-passage, *E*, and the passages *b*.

The improved disc blower resembles the well-known disc engine in its general form and arrangement, and differs from it only in having either the surfaces of the disc or the conical surfaces covered with vulcanised india-rubber in order to secure efficient contact between them without considerably increasing the friction.

Thirdly:—The invention consists of apparatus for superheating steam in its passage from the steam-generating vessel to the working cylinder.

This part of the invention may be best carried into effect by the means illustrated in Figs. 6 and 7. Figure 6 is an end view partly in section of part of a locomotive boiler, with sets of vertical tubes for superheating the steam placed in rear of the ordinary boiler tubes. *A* is the boiler; *B B* are the boiler tubes; *C C* are the superheating tubes; *D D*, *D' D'* are steam cases into which these tubes open, and which, with the said tubes, are shown in perspective in Fig. 7. *E* is the steam pipe leading from the boiler to the superheating apparatus; *F* is the steam pipe leading from the apparatus to the cylinders of the engine; and *d d*, *d' d'* are partitions in the cases, *D D*, *D' D'*, respectively, for the purpose of causing the steam to descend the first set of the superheating pipes, ascend the second, descend the third, and so on until it escapes by the pipe *F*, as indicated by the arrows.

Fourthly:—The invention consists in fitting a valve or door at the throat of the outlet of the flue into the chimney for preventing (by its temporary closure) the cooling down of the furnaces when the fire door is open.

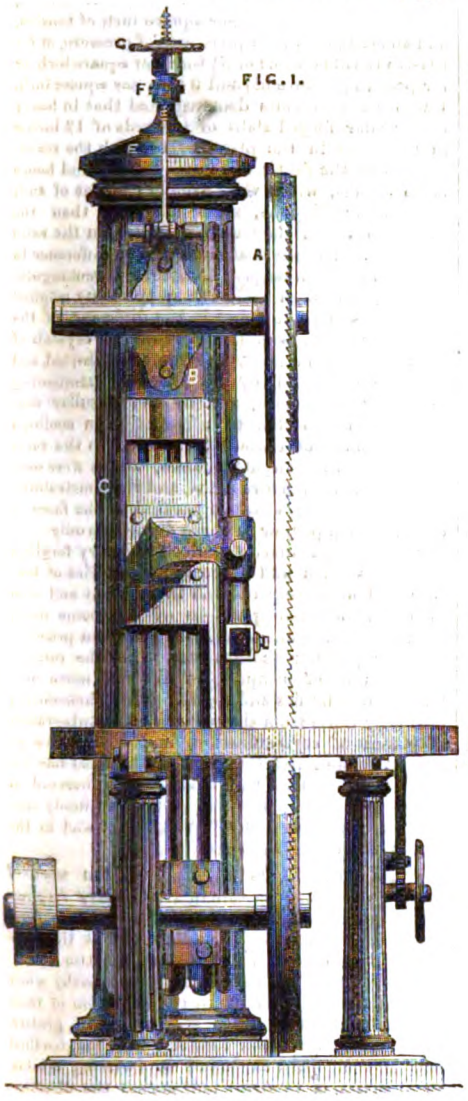
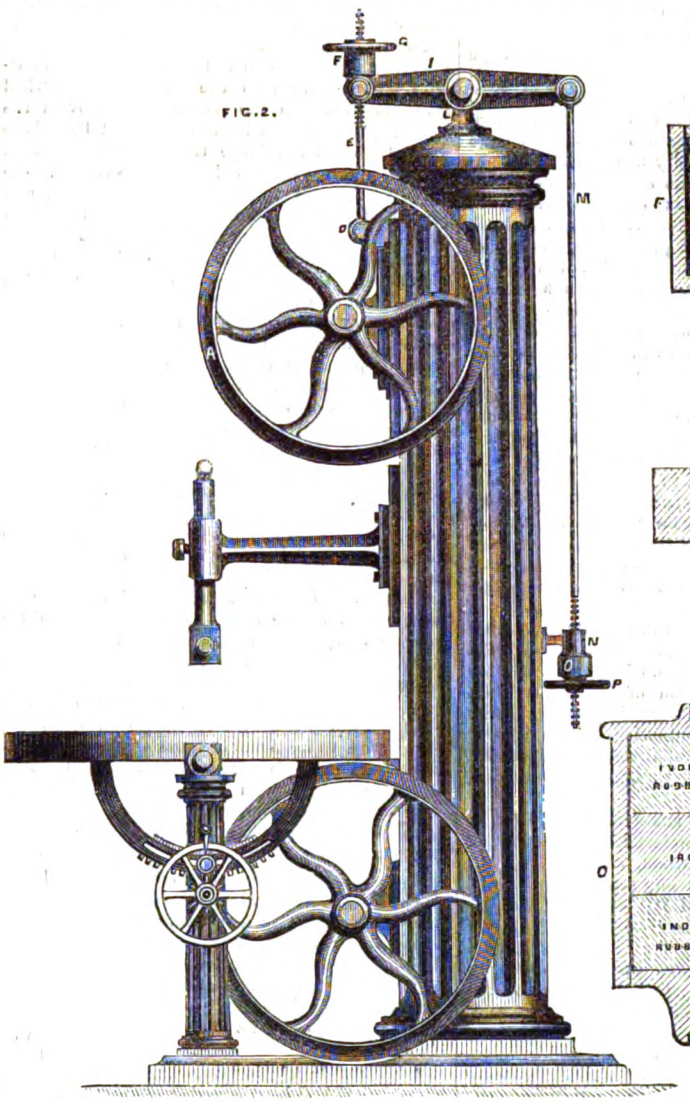
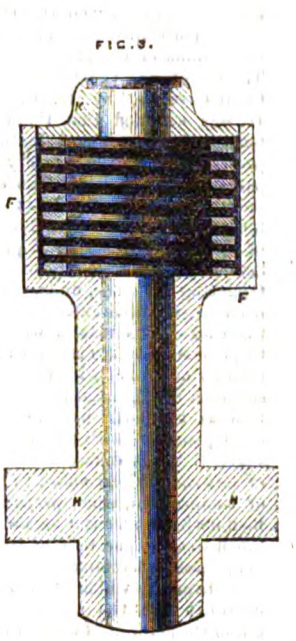
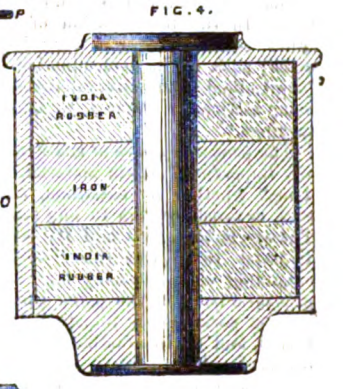
POWIS AND JAMES'S IMPROVED BAND-SAW MACHINES.









POWIS AND JAMES'S IMPROVED BAND-SAW MACHINES.

MESSRS. POWIS & JAMES, the well-known engineers, of Blackfriars-road, Southwark, are manufacturing band-saw machines, embodying a simple, but very valuable improvement. The object is to prevent the breaking or snapping of band-saws from any sudden strain, or otherwise, while at work, or from the cooling of the saws after ceasing to work; also, to allow of the ready adjustment of the bearings of the pulleys over which the saws are stretched.

According to one method of carrying the invention into effect, they connect to the bearing of the pulley over which the saw is stretched an upright rod or spindle, threaded at top. Over the thread or upper part of this rod they pass one arm of a lever, and adjust the rod to the height required by means of a nut, curved at bottom to suit any change of position in the lever, and to allow of the adjustment of the bearings of the pulley. Between the lever and the nut they sometimes place a box or other spring. The lever is centred upon a pin supported upon a pillar. The opposite arm of the lever is connected to a second vertical rod or spindle, the lower end of which is connected to a vulcanized rubber or other spring, and is carried down on the pillar, and is provided with a screw adjustment or not as may be deemed necessary. The bearing of the pulley before named being free to move up and down within certain limits, it follows that upon any strain upon or contraction of the saw, the spring will allow of the bearing yielding, and thus prevent the snapping of the saw.

The inventor of these improvements is Mr. H. Wilson, an engineer in the employ of Messrs. Powis and James. He does not limit himself to the precise arrangement of compound lever, with screw adjustment and spring compensation, or either, as just described, although he believes it best suited to the purposes of the invention; but he also secures the general method of so connecting the moveable bearing of a stretching pulley over which band-saws are stretched to a spring or springs, as to enable the saws to accommodate themselves to any sudden train, and to contract without snapping, whatever may be the particular arrangement of parts emsployed.

In the engravings annexed we have represented a machine in which a band-saw is mounted, according to the method of carrying the invention into effect which we have already described. Fig 1 is a front elevation, and Fig. 2 is a side elevation of the machine. *A* is the upper band-saw pulley, the bearings of which are bolted to the plate *B*; which slides up and down in a dove-tailed groove formed on the pillar *C*. The plate *B* has formed upon it the two lugs or projections *D*, between which is pinned the lower end of the rod *E*. The upper end of this rod is screw-threaded, and passes up through the spring box *F*, having screwed upon the top of it the pressure-wheel *G*. The spring-box *F* which is shown in section and enlarged in Fig. 3, is carried by means of the axes *H* in the end of the beam *I*, and is fitted with a helical spring, on which a loose cap, *K*, rests. The boss on the under-side of the wheel *G* fits into the cap *K*, and by turning the wheel round upon the threaded rod *E*, the moveable cover may be pressed down upon the spring, and the strain upon the band-saw be thus adjusted at will. The beam *I* is carried by brackets *L* on top of the pillar *C*. To the opposite end of it is pinned the upper end of the rod *M*. The lower end of this rod is screw-threaded and passes through a bracket *N*, fastened to the pillar *C*, and also through a spring box *O* and a pressure-wheel *P*. This spring box and pressure-wheel are fitted similarly, but in a reverse position to those already described. The spring, however, in this case consists of two rings of vulcanized india-rubber, one above and one below an iron ring, as shown in section in Fig. 4. With a machine thus fitted, when any excessive strain comes, however suddenly, upon the band-saw, the springs at the extremities of the rods *E* and *M* at once yield and prevent the breaking of the saw. The strain upon the saw may likewise be readily adjusted by turning either of the pressure-wheels as already explained. The saw is not shown in Fig. 2.

MR. BRUNEL has a great connection in the West. He is engineer to the Plymouth Great Western Docks, the South Devon Railway, the South Devon and Tavistock Railway, the Cornwall Railway, &c., &c. Voluminous are the reports issued from "18 Duke-street, Westminster." The Cornwall line is so far completed that a trip has been made over it to Truro, and the Royal Albert Bridge at Saltash is an accomplished fact. The expenditure on capital account amounted on the 31st of December last to £1,423,417. The end of April—or, say, May-day—will, it is expected, witness the opening of the undertaking (which has been twelve years on hand) for traffic. At the half-yearly meeting the speakers expressed great admiration of the Royal Albert Bridge, and of the successful manner in which Mr. Brunel had coped with the difficulties of the country. It was also stated that the bill for the construction of the Falmouth docks would, it was hoped, be passed early in the summer.

WROUGHT IRON AND PUDDLED STEEL.

At the Institution of Civil Engineers, March 1, a paper was read "On the Co-efficients of Elasticity and of Rupture in Wrought Iron, in relation to the volume of the Metallic Mass, its Metallurgic Treatment, and the Axial Direction of its constituent Crystals," by Mr. R. Mallet, M. Inst. C.E. It was assumed that the two questions which formed the prominent feature of the author's present experimental inquiry had remained comparatively untouched. The conditions of manufacture and the resultant qualities had been hitherto too lightly passed over. In consequence of modern engineering requirements, masses of iron, of considerable magnitude, were produced by faggoting together, under heavy forge hammers, from large numbers either of bars, or slabs grouped together. The masses were not, however, found to possess ultimate strength in proportion to the number of bars of which they were composed, the strength of the mass became less in some proportion as the bulk became greater. The author dealt generally with three points of the inquiry, viz:—1. What difference did the same large bars of unwrought iron afford to forces of tension and of compression, when prepared by rolling, or by hammering under the steam hammer? 2. How much weaker, per unit of section, was the iron of very massive hammer forgings than the original iron bars of which the mass was composed. 3. What was the average, or safe measure of strength, per unit of section of the iron composing such very massive forgings, as compared with the acknowledged mean strength of good British bar iron. In the investigation of these questions, other subordinate, but very important points arose; such as the determination of the relative longitudinal and circumferential strength for equal sections of the iron, in massive cylindrical forgings.

The proper measure of the strength of iron, or any imperfectly elastic material, was the "work done," whether by extension, compression, rupture, or crushing, due to any force applied to it. The co-efficients Te and Tr were designed by Poncelet to express this "work done," by an extending or compressing force upon any elastic prismatic body, at the point where its elasticity became permanently impaired, and its form distorted, and at the further point where rupture occurred. It was shown that these co-efficients were the true measures of the safe and ultimate resistance of materials. The crystalline structure of iron was then considered, and quoting from the author's communication to the Royal Irish Academy (*Trans.*, Vol. 23, p. 1, 1855), it was shown to be a law that "Iron, whether in the state of cast or of wrought iron, has the principal axes of its integrant crystals arranged in the lines of least pressure within the mass." If consolidation from fusion took place undisturbed, as in cast iron, the principal axes would be arranged in the directions in which the heat-wave had passed outwards from the body in cooling, which would be perpendicular to its surface contour. The effects of rolling and of hammering masses of wrought iron of different contents were then treated of, and it was shown that what was termed "fibre" was the longitudinal extension of the principal axes of the crystals. The original development of these crystals, under the constraining forces due to change of temperature, &c., was, "cæteris paribus," proportioned to the time given for such development. Thus, in very large forgings, the crystals were generally extensively developed, in consequence of the length of time which the mass had been under the operations of heating and forging.

In order to fix the conditions of strength in wrought-iron under various circumstances, the author undertook to make experiments, under the authority of the Minister of War, and with the concurrence of the Royal Society, when making the forgings for the two 36-inch wrought-iron mortars constructed on his designs for the Government; he then selected specimens of iron, upon which the experiments of tension and compression were tried. The methods were then explained by which the specimens of iron were obtained from the large masses, and the apparatus was described by which the observations were made, when the specimens were undergoing the operations of extension and compression. In cutting and boring into the massive cylindrical forgings to obtain the pieces of iron from the various parts, it was invariably found that there existed, internally, large transverse rents, with jagged and crystalline irregular surfaces, the opposite faces of which were counterparts, and presented distinct evidences of having been torn asunder by contraction from the centre towards the circumference as the mass cooled. It appeared that this action was simply due to the contraction of the external shell, before the temperature of the centre had been perceptibly lowered; this in its turn was cooled, and in contracting produced these visible rents or fissures, and no doubt caused other minor dislocations which detracted from the general strength of the mass. This was evidently the cause of the difficulty of obtaining very large forgings of a cylindrical form quite sound. In solid cylinders, or conic frustra, it must occur *whenever the dimensions were such that the total amount of the contraction of the metal, in any one diameter, from its highest temperature down to that of the atmosphere, as fixed by the circumference of rigidity due to the outer cold shell, exceeded the limit of extension of the iron at rupture, due to the length of the diameter of the interior core, which cooled last.* This was the theoretic limit of size of forging beyond which internal rents must occur. The practical illustration was, that almost all cylindrical shafts of wrought-iron exceeding 12 inches in diameter, were found to have one or more of these rents in them, thus having their strength impaired. This reduction of strength was altogether distinct from any deterioration of quality of the metal, arising from its being alternately heated and cooled and hammered.

The remedy for this play of molecular forces was, to construct and work the large forgings hollow. This course had been pursued with success at the Mersey Iron Works, Liverpool. Both the internal and the external surfaces were thus cooled, and the extremes of internal strains were consequently avoided, and the hollow centre yielded more readily to the forcible compressive grasp of the exterior.

A minute description was then given of all the irons which had been experimented upon, divided into classes, and into the most analogous class was imported CLAY'S PUDDLED STEEL, a comparatively new material, which had been brought into this investigation for the purpose of comparison; and the results were such as promised to be of great practical importance. The general results were the separation of the several classes into two grand divisions: 1. The crystalline or sub-crystalline in fracture, which were always the result of manufacture by the hammer. 2. The fibrous or crystallo-fibrous, which were always produced by the rolling process, but which might be produced by careful and continuous elongation under the hammer. The very weakest wrought iron of all those experimented upon was found to be that cut transversely from the end of a very heavy cylindrical forging, which had been exposed to heat and percussion for nearly six weeks. Its weakness was not due to any metallurgical alteration in the constitution of the metal, but to the changes in its state of aggregation, induced by the process of forging, by the long-continued and unequal heating, and by the hammering. The conclusion deduced, by aid of certain numerical statements, was that practically the iron of very heavy shafts, forged guns, huge cranks, and other similar masses, might be expected to become permanently set and crippled at a trifle above 7 tons per square inch, and to give way by fracture at about 15 tons per square inch by tension, and to completely lose form at pressures of from 15 to 18 tons per square inch. Therefore it followed, that allowing a deduction of one-half, as sanctioned by practice, from the elastic limits of tension and of pressure, for the margin of safety, the iron of such forged masses should not be trusted, for impulsive strains, exceeding about 1¼ ton per square inch of tension, and about 4½ tons per square inch of pressure, or for passive tensile strains of 3½ tons per square inch, or for passive pressure beyond 9 tons per square inch. Further experiments demonstrated that in heavy rectangular forged slabs of upwards of 12 inches in thickness, in the plane of the slab the resistance to all the forces was much higher, and hence large cranks, which were usually cut out of such rectangular forgings, were stronger than the shafts to which they were attached, in the ratio of 8 to 6. The physical cause of the difference in strength between large cylindrical and rectangular forgings, although made from the same original material, was to be found in the difference of the molecular arrangement. The integral crystals of the cylindrical masses were strained, distorted, and partially separated, by the effects of hammering in various directions, and by the peculiar constraining forces due to contraction in cooling; whereas none of these forces acted to the same extent upon rectangular masses, which were only hammered in three directions, and the constraining forces of cooling were all parallel to the faces of the parallelopiped, or in three directions only.

A special peculiarity noticed in heavy forgings was the sudden and extreme inequalities of texture and of strength found in different and even in closely adjacent portions of the same mass, producing great uncertainty of result in practice. Another peculiar feature was, that the rates of extension or of compression did not move uniformly, but by fits and starts. This phenomenon obviously arose from the *per saltum* disintegration of planes of crystallization, and their more or less complete separation in a crystallized but yet ductile body. This had never been observed in fibrous irons, or in those in which the finely elongated crystals were all rolled parallel and in the line of the bar or the sheet.

Within the limits of practice, the work of passive resistance sustainable by heavy forgings was about one-half that of the faggot iron from which they were manufactured; but at the ultimate point of rupture they gave a better result. Heavy forgings were also more trustworthy when exposed to tensile strains in the direction of their length, or to transverse strains, as in girders, which ultimately were resolved into longitudinal strains, than when subjected to twisting strains, as in shafts, or to direct pull across the direction of length. These and other considerations induced attention to the apparently superior power of puddled steel to support the forces by which the ordinary forged masses of wrought-iron were fractured, especially as by the employment of smaller and lighter masses greater strength in shafts, &c., could be secured. One special peculiarity appeared to be, that in the heaviest pieces of this material the internal structure was as fine and close in the grain as it was in the smallest bar. The elastic limit was above that of the best wrought iron, and the elasticity was so much more perfect, that it might be trusted almost up to the elastic limit of about 15 tons per square inch, and in forged masses it possessed this strength nearly equally in every direction. Its extension (beyond the elastic limit) gradually enlarged up to the breaking point, which was often found to reach 48 tons per square inch.

Puddled steel appeared to combine the great strength of cast steel with the ductility and perfect elasticity of the best wrought iron. Its resistance to pressure was very remarkable, being more than double that of harsh crystalline wrought iron, and more than three times that of the best fibrous wrought iron in bars or plates. Thus it might be safely used under a passive strain or load, of 20 tons per square inch, after allowing a margin of one-half for security. Puddled steel would thus evidently become an important practical adjunct in the construction of machinery, in building vessels of light draught of water, and for artillery of the largest calibre. It

Digitized by Google

possessed also the peculiarity of resisting corrosion much better than wrought iron plates, and thus had an additional value for shipbuilding. It was anticipated that it would ultimately be extensively employed for the boilers and even the fire-boxes of the locomotive boiler.

From this investigation nothing of a certain character could be concluded, as to any fixed relation between the strength and the specific gravity of the several sorts of iron experimented upon. the weakest irons—those from the heavy forgings—having generally the highest specific gravities, though always lower than their integrant faggot bars. Thus it appeared that specific gravity was a characteristic to which too great importance had hitherto been attached in relation to strength, both in cast and in wrought iron.

THE ARMSTRONG GUN.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Having read in the *Times* of the 28th Feb., a detailed description of Armstrong's gun and projectile, taken from your Magazine, I beg to say that both are in all the most essential points complete copies of my gun and shot, which have been in the hands of the Government for upwards of 40 years, and that I am the original inventor. Some 45 years ago I invented a breech-loading rifled cannon (also small arms), and by direction of the authorities sent it to Woolwich for inspection, where it has remained ever since. I had a second 6-pounder gun cast, which remained at my own house till 1851, when I sent it to the Great Exhibition, and afterwards brought it under the notice of the late Duke of Wellington, who referred me to the Ordnance Office. In 1852 I laid the matter before the late Lord Raglan, who personally expressed himself highly pleased with the model, and directed me to send the gun itself to Woolwich to be examined by a board of officers. All this was done and the principle of my gun approved of, but the Board declined to recommend the Government to make a large gun and test the matter, although I offered to pay the cost if it failed. From this you will see that I have at this moment two breech loading rifled cannon at Woolwich, one of which has been there for forty years and the other since 1852, both of which may be seen by Mr. Armstrong or any other person. The chamber in my gun being a shade larger than the rest of the bore, the shot cuts its way out, and for this purpose my shot (samples of which are at Woolwich in the guns) are made of iron cased with lead. After loading, the breech in my gun is closed by a cast steel breech-piece, worked by a lever with the greatest facility, and prevents all escape of gas. I have also at Woolwich the model of a gun, showing how ordnance can be greatly increased in strength, and yet reduced to about one-half the usual weight of metal. This I accomplished differently from Mr. Armstrong. While he uses a steel tube and iron bands, I use an iron tube and steel bands, which being driven on to the gun red hot, contract and increase the strength twofold. I may also add that my guns are fitted with a bullet-proof screen, such as suggested by Captain Coles in the *Times* of the 28th February. This screen completely covers the gun, and protects the gunners from all danger. I have also invented a hollow lead shot (also at Woolwich) which possesses great advantages over the ordinary iron in naval warfare. When it strikes it flattens to some extent, and not only makes a hole double the original size of the shot, but instead of cutting a clean hole through a vessel which can be easily filled up, it tears the wood into splinters. I beg to apologise for the length of this letter, but as you have been the means of giving such extensive publicity to Mr. Armstrong's gun, &c., I hope you will in fairness accord me a similar space in your Magazine for this communication,

I am, Gentlemen, your obedient servant,

J. C. DANIELL.

Limpley Stoke, Bath.

LONDON FIRES IN 1858.

TWENTY-EIGHTH ANNUAL REPORT.

By Mr. WM. BADDELEY, *C.E., Inventor of the Portable Canvas Cisterns, Farmers' Fire-engine, Improved Jet-spreaders, &c.*

"The statistics of London fires are by no means devoid of interest, and the time may come when they will form an index to the social advancement of the people; for, in proportion as houses are built more and more fire-proof, and habits of carefulness become more and more diffused, the number of destructive fires will assuredly lessen."—*Knight's London.*

(*Continued from page* 154.)

AMONG the causes of fire the great number of accidents arising from the use of gas is very remarkable, and is a standing disgrace to the science of the age. And not only have these accidents been numerous, but in many cases serious, and in some fatal. A large proportion of these accidents have arisen from the hydraulic joints of gaseliers, and it is greatly to be desired that some efficient substitute for this simple and beautiful contrivance could be hit upon: for so long as water will evaporate, and people will forget to replenish, mischief will continually arise, and when gas and atmospheric air combine in due proportions an explosive compound is produced of the most destructive character.

A very serious explosion of gas took place at *Bell's Life in London* office, in the Strand, in July last; the street mains were being relaid and an escape of gas therefrom entered the cellar; in taking down a light a terrific explosion took place, by which two persons were very seriously injured.

In September the inhabitants of Haggerstone were alarmed by a tremendous explosion taking place at the Independent Gas Works. It appeared that a great escape of gas took place from the mains in the valve or regulating shed, and before any attempt could be made to stop the defect, the gas rushed into the smiths' shop where it ignited, and a fearful explosion was the result, five of the workmen being severely injured.

On the 14th of September an explosion of gas took place at the residence of Colonel Greville, Albert-gate, Knightsbridge, by which three persons were seriously injured; one of whom died after lingering three weeks in great agony. At the coroner's inquest the evidence went to show that the premises had recently been supplied with gas, the fittings having been put up by Mr. Edward Lewis, of Churton-street, Pimlico, under the superintendence of Mr. Joseph Wheeler, of Smith's-place, Chelsea, foreman to the gas company. The was a burner in a strong room on the basement floor, and there appears to have been an escape from some part of the fittings, of which the above-named parties were cognisant, and directed that the door of the strong room should not be closed. Why the defect was not remedied, and this caution rendered unnecessary, did not appear; the caution, however, was disregarded, and Elizabeth Bumplin, housemaid in the establishment of Colonel Greville, going to the closet with a light, an explosion took place, by which she was fatally and two other female servants seriously injured. After hearing the evidence the jury returned a verdict of "Accidental death," and considered that great blame attached to the gas-fitter.

Unextinguished tobacco thrown carelessly about is known to have occasioned no less than 41 fires last year, several of them of a serious character. A fire from this cause took place in February last at No. 13 Young Street, Kennington, by which the front drawing-room and contents were seriously damaged by fire and smoke, but the fire was unperceived by the inmates, and was self-extinguished during the night by its own smoke. The mismanagement of candles continues to prove a fruitful source of mischief; 251 of these accidents have been recorded during the year. Flues in various ways have caused nearly a hundred fires. Gas numbers 131. 47 fires are known to have been wilfully occasioned, and 29 are strongly suspected to have been so. With reference to this matter a writer recently observed that, "while over a hundred millions sterling are in what may be called Vulcan's London Market. it is no wonder that numerous ardent suitors will present themselves from time to time, eager to touch a part of this vast dowry for arson. It is true that the intention is only to convey the portion to legitimate suitors, but where the interests are so large, and the false appearances differ so little from the real, it is very difficult to maintain a just discrimination. In other and less sentimental words, where a hundred millions of money are put down, in the metropolis alone, as a premium for fires, it would be strange indeed if fires did not occur. The temptation is very great to a dishonest man to set his dwelling on fire, and the opportunities are almost complete. Every man's house is his castle, and within this fortress he can generally do what he pleases. The amount of property within its walls, and the combustable materials he may have collected there, are not easily proved, when both have been wholly consumed. The initiated in matters of this kind tell us, that the number of really accidental fires is a mystery whose exposition had better not be attempted. We have no desire to lift the vestal veil. Indeed it is altogether a very delicate affair. The recent trial of Mr. Roper, of Greenwich, shows how almost impossible is the solution of the problem of what is, or is not, an *accidental* fire."

The following tabular analysis exhibits in each instance the occupancy of that part of the premises in which the fire originated, illustrating the relative liability to fire of various trades, manufactories, and private dwellings:—

ASSOCIATION OF FOREMEN ENGINEERS.

On Saturday night last the ordinary monthly meeting of the Association of Foremen Engineers took place, and after four new members had been elected, and the usual routine business was disposed of, Mr. Joseph Newton, Chairman of the Society, proceeded to read his promised paper on the "Influence of mechanical science and mechanical men on the age in which we live." As this was the first occasion on which Mr. Newton had conducted the duties of the office to which he had been recently elected, the paper, to a great extent, might be called an inaugural address. In it the progress of mechanical inventions during the first half of the nineteenth century was very fully traced, and the mighty power exercised in the world by mechanical science at this hour was lucidly demonstrated. The unparalleled advantages which England possesses in her rich stores of mineral wealth, and which tends to make it the school of the mechanical arts, the author also referred to, and said that the very formation of the land—its geological formation, that is—made it of necessity the world's workshop. The persevering industry of the sturdy workers who converted the raw material which Providence had so largely scattered around us into finished machines and apparatuses for the comforts of mankind, was next noticed; whilst the necessity which unhappily exists for the diversion of so much scientific ingenuity and mechanical skill to the preparation of warlike implements was deeply deplored. Our space, however, will not permit us to extend the notice of Mr. Newton's interesting paper, which was well received by the numerous and intelligent audience who listened to it, and which now drew forth a vote of thanks at its conclusion.

We may say that a feeling allusion was made during its delivery to the fact that employers had not as yet extended that amount of sympathy to the Association which might have been expected, and which was ardently desired by its members. Mr. Newton trusted that the day was not distant when they would number many heads of firms as honorary members, for their interests were all quite identical, and they—the members of the Association—discussed no questions of which employers might not have complete cognizance.

It was announced that Mr. Keyte would read a paper on that evening month, on "The best mode of producing heavy castings in iron," and the sitting came to an end.

THE ENGINEERS OF THE ROYAL NAVY.

The following memorial comes to hand as we are on the point of going to press. We most willingly give it insertion, but must necessarily defer any remarks we may have to offer upon it until next week:—

"To the Lords Commissioners of the Admiralty for Executing the Office of Lord High Admiral of the United Kingdom of Great Britain and Ireland.

"*The Memorial of the Inspectors of Machinery Afloat, Chief and Assistant Engineers of the Royal Navy.*

"Humbly Sheweth—

"That your Memorialists have not the same privileges extended to them as Officers of corresponding rank, viz.: Deputy Inspectors of Hospitals, Masters, Surgeons, and Paymasters, inasmuch as these Officers are allowed to retire after a certain number of years and with superior rank.

"That your Memorialists would beg to bring before your Lordships' notice the fact of First Class Assistant Engineers being appointed in charge of Ships bearing Captains and Commanders, although these Ships have a Master, Surgeon, and Paymaster; this necessarily keeps Chief Engineers on half-pay, and at the same time prevents the possibility of Assistant Engineers getting their promotion after a reasonable time. Upwards of 96 First Assistants are now serving, whose period of service exceeds ten years. The average period of Senior First Assistants now employed is about 13 years, dating from the first entry into the service as Engineers; and from the rate of promotion for the last two years it will take from 20 to 25 years before the whole of the present First Class Assistant Engineers can possibly obtain their promotion.

"That part of the Second Masters' time served, and the whole of the Assistant Surgeons', is allowed to count when promoted, whereas your Memorialists only date from the time of their being made Chief Engineers, although a great number were First, Second, and Third Engineers for many years previous to the Regulation of 1847. First Class Assistants also, when promoted on the present scale to Chief Engineers, have none of their time allowed.

"Your Memorialists would likewise beg to represent that there is no pension allowed to the widows of First Assistant Engineers, as is the case with Assistant Surgeons, after 10 years' service, although the various changes of temperature to which Engineers are subjected, as also the great physical exertions required in the performance of their duties, cause a much greater wear and tear of constitution, and, therefore, more deaths in proportion, than with any other class of Officers.

"Your Memorialists humbly trust, that the importance of the Steam Branch of the Service is such as will induce your Lordships to take their case into your favourable consideration, and, as in duty bound your Memorialists will ever pray, &c."

LIST OF NEW BOOKS.

Taylor's Builder's Price-book, 1859, 4s.
Todhunter's Plane Trigonometry, 5s.

New Army Blank Cartridge.—The General Commanding-in-Chief has sanctioned the adoption of a new pattern blank cartridge, proposed by the Superintendent of the Royal Laboratories, for assimilating the method of loading with blank to that of loading with ball cartridge, and cartridges of this description are now ready for delivery. They are composed like, the service ball cartridge, of an inner bag, containing the powder; mock bullet, consisting of a paper bag, with a muslin bottom, filled with fine grain powder; and an outside bag to contain both. To insure the flash of the discharge igniting the powder in the mock bullet, and to prevent its being projected from the musket entire, a portion of the bottom of the outside bag is cut away. No portion of the paper requires to be torn off.

NOTICES.

We have thought it advisable to dispense with the "Notes" of our Country Correspondents, replacing what was most valuable in them by a column or two of Gossip, by which means we shall gain more space for the mass of scientific matter which every week presses for publication. None of our readers will, we believe, disapprove of the change.

The Mechanics' Magazine will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to E. A. Brooman, at the Post Office, Fleet Street, London, E.C.

The demand for Mr. E. J. Reed's paper—

On the Modifications which the Ships of the Royal Navy have Undergone during the Present Century, in respect of Dimensions, Form, Means of Propulsion, and Power of Attack and Defence,"

has been so great that the Journal of the Society of Arts, the Mechanics' Magazine, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

OUR WEEKLY GOSSIP.

The death of Mr. Thomas White, the founder of the dockyards at Cowes, Isle of Wight, is announced. Mr. White is succeeded by his sons, Messrs. J. and R. White, who at present employ about 400 men and apprentices. The deceased gentleman was in his 86th year.

It is stated that the Harbour of Refuge Commissioners, in their forthcoming report, will recommend two Scottish Ports—Wick and Peterhead—as desirable points for the expenditure of some of the public funds. The Commissioners are said to be prepared to recommend, on these and some Irish and English ports, an outlay of £2,000,000.

The ceremony of opening the "Tyne Docks," at Jarrow Slake, which have been constructed by the North-Eastern Railway Company, has taken place with becoming pomp. The piece of plate voted by the Directors, with £1,000, as a testimonial to Mr. Harrison, the engineer, was presented at the dinner.

Glycerine, though comparatively a new discovery, is most extensively used in the arts; and scarcely a month passes without developing some new mode of application, confirmatory of its value. The spent lees of the soap makers (from neutral fats) contain on an average fully 2 per cent. of glycerine, 1½ per cent. of soda, and 8 per cent. of common and other salts. By a process just patented by Mr. Reynolds, a London chemist, the glycerine can be separated from saline and other matter at a very trifling cost, the expense of the process being in some instances covered by the value of the regained salts.

At the risk of wearying some of our readers with the incessant sound of guns, we must, we presume, jot down the current gossip respecting them. The steam-transport *Contest* has just landed at Woolwich pier 16 heavy siege guns manufactured by the contractors at the Lowmoor works. A similar number has been disembarked weekly from the same firm for many weeks past, together with a corresponding number from other contractors. None of the guns cast in the standard foundry of the Arsenal have been issued for service. They are ordered to be retained for experimental purposes.

Sir William Armstrong's gun—over which the Woolwich officials continue to make themselves excessively ridiculous—was brought out again on Monday in the Royal Horse Artillery square for

Digitized by Google

drill practice. The entrances to the square were strictly guarded by extra sentries and non-commissioned officers of the corps, who were ordered to exclude, without exception, all persons not wearing the uniform of officers of the garrison. At the termination of the drill the gun was restored to its temporary shed and secured from observation and inspection by lock and key. "A party of Engineer officers proceeding to the literary and scientific institution of the garrison were informed," says the *Times*, "by the sergeant on special duty at the gate that they could not be allowed to pass. He, moreover, added that the General himself would not be admitted out of uniform. These restrictions are sanctioned by the commandant of the garrison." Sir William Armstrong will begin, we fear, to lament his share in all this contemptible child's-play.

Mr. John Anderson, F.R.S., inspector of machinery to the War Department in Woolwich Arsenal, has been very judiciously appointed assistant-engineer of rifled ordnance, to carry out, in conjunction with Sir W. Armstrong, the manufacture of the new guns for the Royal Artillery. Mr. Anderson, whose scientific direction of the machinery department of the Royal Arsenal has been marked by various productions for which he was most liberally rewarded by Government grants and otherwise, was a short time ago presented with a compensation of £3 000 by the Council of the Board of India for his invention in the manufacture of leaden bullets. He is a very fit man for the new appointment. More civilian appointments are also spoken of as about to take place in the Laboratory and the other manufacturing departments of the Arsenal.

Accounts continue to reach us of successful experiments with Sergeant Warry's breach-loading cannon. We examined this gun at Brompton a few days since, but found it advisible to defer giving a detailed description of it for a few weeks. On the same day we had the satisfaction of being shown over the model-room and libraries of the Royal Artillery at Brompton, by colour-sergeant Clark, whose soldierly courtesy was only to be equalled by his intelligent acquaintance with the admirable collection of models and books there brought together. The reading-room, which the non-commissioned officers of the force have fitted up for themselves, is an exceedingly pleasant apartment. In that apartment, curiously enough, we first observed that the *Times* had reproduced our remarks on the Armstrong gun, thus giving them to that vast military class which a scientific journal can hardly hope to reach. We were gratified to learn—and indeed to observe for ourselves—that Colonel Sandham, the gallant chief officer of Artillery at Brompton, took an unaffected interest in the educational appliances with which the officers and men under him have been furnished.

On Tuesday week a lecture was delivered at the United Service Institution—Major-General S. Stanhope in the chair—by J. Macintosh, Esq., "On the Use of Combustible Materials in the New Strategies of War." The lecture was a statement of those devices with which our readers are now familiar as forming Mr. Macintosh's new system of warfare. It was attended by the Earl of Shrewsbury, Lords Overstone, Ingestre, and Ranelagh; Lieut.-General Sir W. Codrington, K.C.B., General Cannon, Vice-Admiral Ryder Burton, Major Farrell, Captain Stopford, R.N., and many members of the naval and military professions.

It is difficult to see what will be the end of the dispute about the dams in the Nene. Some eminent members of the Chancery bar are reported to have expressed an opinion that the members of the acting committee of the Nene Valley Commissioners are personally liable for the repayment of £37,000 alleged to have been misappropriated in the execution of works in the upper division before the works in the lower division of the river were completed. It is stated that actions are about to be commenced against the Commissioners on behalf of the individuals who were imprisoned on warrants, on a charge of felony, for removing the dam at Waldersea, after the local magistrates had made an order for its being taken away.

With reference to the Plymouth Great Western Docks, it may be interesting to give the following particulars. The Milbay pier, which was the first portion of the work constructed, projects from the extreme eastern point of the harbour of Milbay, with a water frontage of 400 feet, and is from 40 ft. to 90 ft. wide. Coal stores are erected on a portion of this pier, adapted to supply steamers with coals with despatch, and the depth of water at the pier is from 18 ft. to 40 ft. below low water spring tides. Within the pier—about 100 ft from it and sheltered by it—is an iron pontoon, 300 ft. long and 40 ft. wide, with a depth of water from 12 ft. to 24 ft. below low-water spring tides. The stores of this pontoon are capable of containing 4,000 tons of coal, and this portion of the harbour is employed in the accommodation of steamers. There is a large inner or floating basin at the extreme end of the bay, containing an area of 13 acres of water, surrounded by spacious quays. Within the floating basin, at the south-western end is a graving dock, 367 ft. long.

The new telegraph line to the Continent, by way of Cambridge and Norwich, is not yet in operation, but is being actively carried out. At Newmarket, the wires are carried underground through the town, and also on each side of it for nearly a mile.

The latest bit of gossip that has reached us is to the effect that Sir William Armstrong applied, two days since, for another patent for improvements in the construction of cannon and projectiles. We refrain, at this early stage of his protection, from hinting even at the nature of the improvements. In due time, however, they shall be produced. The application has been made rather with the view of preventing others from interfering with Sir William's proceedings, than with that of securing privileges for the inventor.

GRIFFITHS' SCREW PROPELLER.—Mr. Griffiths writes as follows:—"Mr. Isherwood in his 'Engineering Precedents for Steam Machinery,' as quoted by you in your number for Feb. 18, seems to labour under the delusion that by rounding the corners of a common screw propeller, and providing it with a spherical boss, he has made a Griffiths' propeller. This also seems to be a prevalent error in this country, and is the plan frequently followed to evade my patent rights. They are, indeed, infringements, worse than useless as regards the perpetrators, but damaging in their effects to me, as they are calculated to give an erroneous idea as to my propeller and its capabilities. The result of these alterations is to destroy the common screw, without gaining any of the advantages to be obtained from the use of my patent screw propeller, in which the broader part of the blade is placed near the boss, at which place the blade of the ordinary screw is reduced to its smallest proportions. A reference to No. 5 of your New Series, where my screw is figured, will show your readers that what I state is correct. Careful experiments have convinced me that the centre of the screw is the most effective propelling part. In the abortions made by cutting away the common screw my propeller is merely caricatured, as forms are distorted in shadows.—ROBT. GRIFFITHS, 69 Mornington-road, Regent's-park, N.W., March 3, 1859.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated December 18, 1858.

2898. I. Ketchum, of Liverpool, Merchant. Improvements in the method of roasting meat, poultry, game, by basting the same, and in the method of manufacturing the necessary apparatus for so doing.

Dated January 22, 1859.

200. L. A. Drouin, of Paris, Joiner. Improvements in covering joinery work with metals or metallic alloys, and apparatus for the purpose.

Dated January 29, 1859.

270. J. J. A. de Bronac and A. J. M. Dcherrypon, Civil Engineers, of Paris. A new or improved process for treating metallic sulphurets, phosphurets, arseniurets, antimoniurets, and particularly sulphuretted ores of lead, antimony, copper, silver, zinc.

Dated February 1, 1859.

284. R. Needham, of Dukinfield, Engineer. An improved water-gauge for steam-boilers.

Dated February 5, 1859.

336. T. R. Averst, of Newenden, Kent, Book-keeper. Improvements in breech-loading guns and other fire-arms. A communication from J. H. Sears.

Dated February 8, 1859.

353. W. Waller, of Chesterfield, Mechanical Engineer. Improvements in agricultural or farm implements or apparatus. Partly a communication from W. Rogers.

Dated February 9, 1859.

368. G. Bower, of Saint Neot's, Huntingdon, Gas Engineer. Improvements in apparatus for the manufacture of illuminating gas.

Dated February, 10, 1859.

376. W. A. Covert, of Long Island, New York. An improved self-acting railway switch. A communication from C. L. Spencer.

Dated February 11, 1859.

386. H. Bruce, of Currie, Midlothian, Paper Manufacturer. Improvements in apparatus for the manufacture of paper.

Dated February 12, 1859.

396. C. R. Moate, of Old Broad-st., Metal Broker. Improvements in the manufacture of nuts, screw bolts, spikes, and other headed fastenings. A communication from J. Gibbs, of Alexandria.

Dated February 15, 1859.

417. C. L. Roberts, of Clerkenwell. The manufacture of an improved cigar.

419. F. Walters, of Sheffield. The application of the waste heat from puddling furnaces.

421. J. Paterson, of Wood-st., City, Manufacturer. Improvements in brace buckles and loops, and in braces.

423. G. Bedson, of Manchester, Manager. Improvements in joining wire for telegraphic and other purposes.

Dated February 16, 1859.

424. J. F. Tourrier, of Manchester-st., Manchester-sq. Preventing oscillation of the last carriage of a railway-train, and giving rigidity and steadiness throughout the train.

425. M. Crawford, of Liverpool, Ship Chandler. An improved anti-fouling metallic varnish applicable to ships' bottoms and other similar purposes.

426. S. Bailey, Mining Engineer, of Wednesbury. Certain apparatus for preventing the skip in mine operations being pulled over the pulley on which the rope or chain works, to which such skip or cage may be attached, as well as preventing the skip or cage re-descending until put in motion for that purpose.

427. R. Cookson, of Layton Hawes, near Blackpool, Gentleman, and C. W. Homer, at Castle-hill, near Northwich, Civil Engineer. Improvements in machinery for making bricks, tiles, tubes, and other articles of plastic materials, and in the mode of joining drain pipes.

428. C. E. Wright, of Nottingham, Commercial Traveller. Improvements in means or apparatus employed in the nursing or treatment of infants.

429. R. J. S. Pearce, of Fleet-st., Machinist. Improvements in weighing and dynamic machines.

430. P. M. P. Bourjeaard, of Davies-st., late Surgeon in the French Navy. An improved apparatus for supporting the womb.

431. W. E. Newton, of Chancery-lane. An improved mowing machine or grass harvester. A communication from J. P. Adriance.

432. A. V. Newton, of Chancery-lane. An improvement in the construction of brushes. A communication from I. W. Shaler.

433. W. E. Newton, of Chancery-lane. Improved machinery for making bricks. A communication from A. Mitch, of Berlin.

434. W. H. Horstmann, of New York. Telegraphic cables and the mode of constructing the same and laying them down.

435. J. J. Russell, of Wednesbury. Improvements in machinery used for heating and welding the edges of the plates used in the manufacture of cylinders and other articles.

436. W. A. O'Doherty, of Eastcheap. An improvement in black-lead pencils and pencil cases. A communication from D. D. Sweet.

437. J. Seguin, Doctor of Medicine, of St. Maurice, France. Improvements relating to the employment of moving power arising from the tides and its application to manufacturing, agricultural, and other purposes.

439. J. Breeden, of Birmingham, Manufacturer. New or improved machinery for the manufacture of taps or stop-cocks, and fittings for gas, steam, and water pipes.

440. J. Eason, of Oxford-st. Improvements in apparatus applicable to tanning, dyeing, and obtaining extracts from vegetable, animal, and mineral substances.

Dated February 17, 1859.

441. S. T. Cooper, of Upper Clapton, Gentleman. Improvements in the use and application of artificial light.

443. H. Y. D. Scott, of Brompton Barracks, Captain Royal Engineers. An improvement in the manufacture of cement.

444. B. Saillard, of Lamb's Conduit-st., Electrotyper. An improved mode of obtaining printing-plates from collodion pictures.

445. P. E. Fraissinet, of Paris, Civil Engineer. A new or improved structure of iron, applicable for paving, flooring, bridges, gratings, girders, and other like purposes.

446. T. Cattell, of Euston-sq., M.D. Improvements in treating and purifying gutta percha.

447. F. W. Emerson, of New Charlton, Mining Engineer. Improvements in the treatment of certain ores of lead, and obtaining from them valuable primary and secondary products.

Digitized by Google

449. J. H. Johnson, of Lincoln's-inn-fields. Improvements in apparatus for propelling and steering vessels and other floating craft. A communication from J. Eton.

Dated February 18, 1859.

450. J. J. Cole, of Essex-st., Strand. Improvements in venetian and other suspended blinds, and in the method of hanging and working them.

451. C. Garton, of Bristol, Brewer. An improved method of treating cane sugar, in order to render it fitter to be employed in brewing, distilling, and wine and vinegar making.

452. H. Swaisland, of Clerkenwell, Mathematical Instrument Maker. Improvements in box sextants.

453. G. Wallis, of Stretton, Stafford, Artist. A new or improved method of engraving, applicable to the production of printing surfaces and the ornamentation of metallic and other surfaces.

454. G. Kammerer, of Lombard-st., Merchant. Improved gearing for gins or horse mills, applicable for grinding, winnowing, and other purposes requiring motive power. A communication from Messrs. Lotz, of Pouancé, France.

455. W. Clark, of Chancery-lane. Improvements in emptying cesspools, and in raising other fluid and semi-fluid matters. A communication from P. T. Joly, jun., of Paris.

456. W. Clark, of Chancery-lane. Improvements in pressure gauges. A communication from L. Droissart, of Paris.

457. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the manufacture of textile fabrics and in the machinery or apparatus employed therein. A communication from A. de Chavagneur, of Paris.

Dated February 19, 1859.

458. P. A. J. Dujardin, of Lille, France, Physician. Improvements in the printing apparatus of railway telegraphs.

459. A. R. L. de Normandy, of Judd-st., Analytical Chemist. Improvements in an apparatus for obtaining fresh water from salt water.

461. W. Clay, of Liverpool, Iron Manufacturer. Improvements in the manufacture of deck and other beams and of angular and other bars of various forms.

463. S. Wheatcroft, of New North-road, Engineer. Improvements in the method of, and the means for, uniting lace to blond and other fabrics, and also in the apparatus used for manufacturing or converting the same into bonnet and cap fronts, rouches, and such like similar articles of millinery.

464. C. F. Vasserot, of Essex-st., Strand. An improved apparatus for manufacturing the strands of wire-ropes. A communication from J. B. Pieux-Aubert.

465. C. F. Vasserot, of Essex-st., Strand. An improved carding machine. A communication from V. Madeline-Morin.

467. F. P. J. Van den Ouwelant, of Paris, Gentleman. Improvements in apparatuses to be applied to fire-places for obtaining a more complete combustion of the fuel employed therein.

Dated February 21, 1859.

468. G. Paul, of Glasgow, Mechanic. Improvements in spindles and flyers.

469. O. Blake, of Blackwall. Improved machinery or apparatus used in the manufacture of glass.

470. G. McCulloch, of Manchester. Improvements in machinery or apparatus for spinning, doubling, and throwing silk, and doubling other fibrous materials.

471. T. Wilson, of Birmingham, Engineer. Improvements in the manufacture and construction of ordnance.

472. A. Belpaire, Engineer, of Brussels. Improvements in the reversing gear of locomotive and other steam engines.

473. G. Humphrey, of Deptford, Engineer. Improvements in meters for measuring fluids and gases.

475. R. Jobson, of Wordsley, Iron Founder. Improvements in supplying water or other fluid to axletree boxes and other journal bearings, to lubricate the same.

477. R. W. Johnson, of Oldbury, Worcester, Railway Carriage Builder, and W. Stableford, of the same place, Manager. Improvements in axle boxes.

Dated February 22, 1859.

479. T. Smith, of Chatteris, Cambridge, Watchmaker. Floating wheels for driving machinery.

480. W. Soelman, of Bennett-st. Improvements in the construction of propellers.

481. J. Grimond, of Manchester, Manufacturer. Improvements in the treatment and preparation of jute and other fibrous materials, and in machinery or apparatus employed therein.

482. J. Curtis, of Drury-lane. The manufacture of military sash net, and machinery to be employed therein.

484. J. Hine, of Clerkenwell, Cabinet Maker. An improved book slide.

485. E. Lund, of Manchester, Gentleman. Certain improvements in the manufacture of fabrics or textures to be used in the construction of umbrellas and parasols.

486. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. A method of fixing tannin upon textile fibres, and the employment thereof in dyeing black and dark colours. A communication from M. Verguin, of Lyons, France.

487. T. R. Harding, of Leeds, Hackle Pin Maker. Improvements in the manufacture of card surfaces to be used in preparing fibrous materials.

Dated February 23, 1859.

489. A. W. Smethurst, of Chorley, Lancaster, Cotton Spinner. Improvements in machinery for driving looms for weaving.

491. W. Ashton, & Heaton Norris, Lancaster, Manager. Improvements in gas regulators.

493. U. Scott, of Camden Town, Civil Engineer. Improvements in carriages, and various parts of the same, which parts may be applied to vehicles of any description.

495. S. R. Samuels, of Nottingham. Improvements in twist lace machines.

497. G. Turnbull, of Calcutta, Civil Engineer. Improvements in the permanent way of railways.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

524. F. Brignolcs, of Duke-st., Adelphi. The disinfection and rectification of alcohols, by the separation of the essential and other oils from the alcohol. A communication from St. Cyr Prieur, of Avignon, France. Dated February 26, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, March* 8, 1859.)

2375. M. Mason. Stands or stages.
2384. M. Mason. Printing machines.
2386. C. Wicland. Time keepers.
2389. J. Luis. Boring machine. A communication.
2392. J. Kinsey. Steam engines and pumps.
2393. C. Cheyne. Floors and ceilings.
2405. T. Railton. Cap fronts.
2408. B. Foster and P. Smith. Spinning and doubling.
2418. J. Wright. Propelling. A communication.
2419. G. Zanni. Magneto-electric machines.
2422. L. J. Lewis. Fastenings.
2423. J. Morris. Printing fabrics.
2433. J. Cariss. Switch box and gear.
2434. E. Maynard. Telegraph cables.
2435. C. Perley. Disconnecting boats.
2438. M. A. F. Mennons. Railway brakes. A communication.
2442. R. C. Smith. Buoy.
2444. M. L. J. Lavater. Cartridges.
2458. J. Fowler, jun., R. Burton, and D. Greig. Applying power to ploughs.
2465. C. Mather. Drying yarns.
2471. T. Till. Nails, &c.
2472. T. Briggs. Mattresses, &c.
2478. S. Davey. Blasting powder.
2489. J. Jackson, A. Fisher, and J. J. Harney. Strips of steel.
2490. J. Platt. Spinning and doubling.
2501. J. F. Amblet and A. Polart. Elastic fabrics.
2505. J. L. Jullion. Paper.
2508. J. Felix. Castors.
2510. W. Clark. Signals. A communication.
2513. A. V. Newton. Obtaining extracts. A communication.
2532. M. Benson. Rails for railways. A communication.
2538. T. F. Cocker. Wire and strips of steel.
2540. J. G. Martien. Iron.
2547. J. Courage and F. Bennett. Furnaces.
2561. A. Dick. Yellow pigment.
2594. J. Platt and H. Chubb. Bricks or tiles. Partly a communication.
2595. W. Clark. Tanned hides. A communication.
2622. W. Clark. Purifying phosphates of lime. A communication.
2629. A. V. Newton. Transmitting motive power. A communication.
2650. S. W. Johnson and J. Varley. Pressure and vacuum gauges.
2666. A. V. Newton. Bolts and Rivets. A communication.
2685. E. Dixon and J. Fisher. Iron tubes.
2695. J. Tangye. Hydraulic presses.
2787. J. Jobson. Stoves and fire-places.
2792. J. Dawson. Raising the nap on cloths.
2859. J. Webster. Copper and zinc.
2898. I. Ketchum. Roasting meat.
27. C. B. Blyth. Treating fibrous materials.
83. W. Tillie. Shirts and fronts.
216. J. Fowler, jun., R. Burton, D. Greig, and J. Head. Agricultural implements.
227. J. White. Facilitating respiration.
275. T. Wilson. Fire-arms.
309. W. Clayton and J. Goodfellow. Metallic pistons.
348. T. Moss. Paper and ink.
353. W. Waller. Farm implements. Partly a communication.
365. J. Crossley. Steaming yarns.
374. J. Young. Knobs and roses.
386. H. Bruce. Paper.
401. H. Gardner. Preparing fibres.
413. J. Copcutt. Obtaining light.
426. S. Bailey. Mine Cages.
439. J. Breeden. Stopcocks, &c.
440. J. Eason. Tanning, dyeing, &c.
452. H. Swaisland. Box sextants.
459. A. R. L. de Normandy. Obtaining fresh water.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 4, 1859.

2006. W. H. Child.
2027. B. Hockin.
2031. A. Lamb and J. White.
2041. J. Rowley.
2059. W. Toshach.
2066. J. L. Hinks.
2077. J. Turner.
2401. G. M. Casentini and J. O. Barnard.
2804. J. V. Scarborough.
2984. H. C. Vion.
50. J. H. Johnson.

Sealed March 8, 1859.

1811. W. Smith.
2043. C. N. Kottula.
2044. J. Tatlow and H. Hodgkinson.
2056. F. A. E. G. de Massas.
2058. D. Cheetham.
2071. W. Thomson.
2113. H. Barrow.
2175. J. Morrison.
25. R. Tempest and J. Tomlinson.
75. F. Lehr.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

528. J. Reading.
534. F. Kaselowsky.
543. J. E. Hodges.
545. J. E. Hodges.
549. T. Lambert.
567. A. Newburger.
570. J. Downie.
576. H. Cooke.
609. G. Rees.
626. R. W. Winfield, J. Simms, and T. Lloyd.
631. C. Randolph and J. Elder.
761. J. Mc Lean.

PATENT ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1856. 761. J. McLean.

LIST OF SPECIFICATIONS, &c.

Published during the week ending March 4, 1859.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 1571, 1604.

Boilers and their Furnaces, 1592.

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1550.

Ships and Boats, including their fittings, 1554, 1561, 1576, 1602.

Cultivation of the Soil, including agricultural and horticultural implements and machines, 1549, 1591, 1620, 1622.

Food and Beverages, including apparatus for preparing food for men and animals, 1556, 1560, 1578, 1586, 1615.

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1555, 1579, 1596, 1603, 1619, 1624.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c., 1625.

Lighting, Heating, and Ventilating, 1557, 1565, 1567, 1570, 1580, 1589, 1598, 1599.

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1552, 1564, 1568, 1570, 1572, 1588, 1611.

Metals, including apparatus for their manufacture, 1551, 1569, 1575, 1608, 1613.

Chemistry and Photography. *None.*

Electrical Apparatus, 1573, 1587, 1605, 1606, 1607.

Warfare, 1593, 1595, 1623.

Letter Press Printing &c. *None.*

Miscellaneous, 1550, 1553, 1558, 1559, 1562, 1563, 1566, 1574, 1576, 1577, 1581, 1582, 1583, 1584, 1585, 1590, 1597, 1600, 1601, 1606, 1609, 1610, 1612, 1614, 1616, 1617, 1618, 1621.

1549. C. N. Kottula. *Improvements in the manufacture of manure.* Dated July 9, 1858.

This consists in the employment, in the manufacture of manure, of a compound of dissolved resin, or resin saponified with alkaline lye and lime, whether the resin be dissolved or saponified, and the materials be combined at the first, or at any subsequent stage of the manufacture. *Patent completed.*

1550. F. H. Edwards. *Improvements in pneumatic springs for railway carriages and other purposes.* Dated July 9, 1858.

This consists in the use of an air-cushion contained within a metallic cylinder, having its inner end closed, such cushion being acted upon and compressed by a plunger of such form as is calculated to restrict the area thereof exposed to unsupported pressure, and to maintain that area invariable during the whole travel of the plunger. *Patent abandoned.*

1551. J. M. Rowan. *Improvements in manufacturing wrought-iron wheels and bosses, or centres, and in the*

Digitized by Google

mode of, and furnaces for, heating the same during such manufacture. (A communication.) Dated July 9, 1858.

This relates to a method of forming parts of wrought-iron wheels or hubs or bosses for screw propellers, and consists in making the butts of the spokes for the hubs of wrought-iron wheels of an angular, curved, or zig-zag form, so as to ensure a lap-welded hub, when they are brought and welded together; 2, to the mode of, and apparatus for heating the parts of wheels or bosses that are to be welded together, and consists in heating those parts all over simultaneously by causing the heat to act from above and below alternately. *Patent completed.*

1552. W. E. NEWTON. *Improvements in the construction of umbrellas and parasols.* (A communication.) Dated July 9, 1858.

This relates to a mode of constructing the frames of these articles of wire, and consists in forming the ribs with their eyes of single pieces or lengths of wire. The eyes of the ribs and stretchers are formed by bending or turning up the wire. *Patent completed.*

1553. A. PORECKY. *Improvements in the manufacture of certain articles of whalebone, horn, tortoiseshell, and other corneous matters, or the artificial imitations thereof.* Dated July 10, 1858.

This consists, 1, in making busks for ladies' stays from any of the materials mentioned or included in the title of this invention. The inventor takes strips of such material, to which he gives a fluted or corrugated form, thereby imparting thereto the necessary strength and elasticity, though of smaller bulk and less weight than usual, and at the same time forming channels through which perspiration may pass off, and air be admitted to the body. 2. In making from the materials above mentioned various articles, as walking sticks, whips, fishing-rods, penholders, &c., to do which he takes strips of such materials, and bends, presses, or forms them into a plain, fluted, ornamental, flexible or rigid tube, or some longitudinal section thereof. The said hollow articles may then be either wholly or partially filled with a suitable composition, or they may be left unfilled, thereby allowing of their sliding one over the other like a telescope. *Patent abandoned.*

1554. G. H. WAIN. *Improvements in reefing and furling sails.* Dated July 10, 1858.

The patentee claims the application of a revolving spar or roller made fast to any portion of the sail, which spar is made to turn round and furl up the sail, in two directions, "with the application of every such spar for every such purpose." The peculiar arrangement of ropes or other haul-yards for giving the required rotary motion to the revolving spar, and the combination and general arrangement of machinery and parts described, and for the purpose set forth. This invention is not described apart from the drawings. *Patent completed.*

1555. W. LANGSHAW. *Improvements in machinery or apparatus for wearing fancy looped or knotted fabrics.* Dated July 10, 1858.

This consists of an improved needle with improved mechanism for working the loom. The patentee employs double bearded swivel-hooked needles, each double hook working on a pin, so that when one side seizes fresh yarn, the other side gives off a loop without any impediment. The improved mechanism consists of certain improvements in the modes of giving the pattern to the fabric in the taking-up motion, and in the general arrangement of the loom. He also employs improved temples, consisting of two or more rollers or pulleys having projecting spikes which pass through the fabric and keep it extended, the pulleys revolving as required with the passage of the work. *Patent completed.*

1556. J. F. WATSON and V. B. FADEUILHE. *Improvements in the preparation of cocoa and chocolate, and also of nutritive compounds from the seeds of the plant called Soja hispida and Cicer arietinum.* Dated July 10, 1858.

This consists in mixing with cocoa, &c., dried milk. It also consists in combining the flour produced from the seeds of the *Soja hispida* and the *Cicer arietinum* with cocoa, &c., and dried milk, or with the juices of meat. *Patent abandoned.*

1557. P. BURRELL. *Improvements in ventilating sewers and other receptacles of sewage.* Dated July 10, 1858.

Here pipes are laid along the lines of sewers just above them, and at intervals connexions of small diameter are made between the interior of the sewers and the pipes. The pipes are arranged in connexion with apparatus for withdrawing the air and gases from the pipes into the apparatus, which consists of vessels similarly constructed to gasometers, and moved up and down by suitable power. The gases may be forced through water, with such chemicals therein as will arrest the valuable products in the gases; or the gases may be subjected to fire, to decompose them. *Patent abandoned.*

1558. W. NORTHEN. *The application of stoneware or earthenware, coloured or plain, to improved and original designs.* Dated July 12, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 620, No. 1846, of the MECHANICS' MAGAZINE. *Patent completed.*

1559. J. LOACH and J. COX. *Certain improvements in ornamenting glass with perforated metallic and other plates.* Dated July 12, 1858.

This consists in producing ornamental panes for windows by a middle, perforated, or open-work plate or sheet. Also in a mode of ornamenting certain articles by a perforated plate or sheet placed or secured on the back or inside of the plate or other glass cut or finished to the shape and size required. *Patent completed.*

1560. J. MACINTOSH. *Improvements in apparatus for the manufacture of articles of confectionery.* Dated July 12, 1858.

This relates to the manufacture of "pan goods," the necessary action being produced by the rotation of the primary driving gearing. The pan does not revolve, but receives a powerful differential action, which rolls the articles in the pan to all sides and shapes them with great rapidity and accuracy. *Patent abandoned.*

1561. M. A. F. MENNONS. *An apparatus for stopping leaks in ships.* (A communication.) Dated July 12, 1858.

This consists of a double coil of waterproof tissue, or metallic gauze, rendered impermeable, which coil being suspended to the sides of the vessel is unrolled by lines arranged and worked from the deck. *Patent abandoned.*

1562. M. A. F. MENNONS. *Improvements in the construction of fire engines and similar apparatus.* (A communication.) Dated July 12, 1858.

A complete specification of this invention was filed with the application. The invention is not described apart from the drawings. *Patent completed.*

1563. R. A. BROOMAN. *Certain new or improved machinery for the manufacture of wire heddles.* (A communication.) Dated July 12, 1858.

This consists of a pair of revolving cylinders, with appurtenances for drawing in the wire, gripping, twisting, and discharging the same, whereby the heddle is made and discharged automatically. The invention is not fully described apart from the drawings. *Patent completed.*

1564. D. S. WILTON. *Improvements in pianofortes.* Dated July 12, 1858.

Here each string is wound round and fastened to a lever with a projecting curved surface on which the string rests. The lever moves on one end, which rests on a ridge or projecting plate fixed to another plate at the upper part of the pianoforte, and into which the tuning screw enters. Through the lever a tapering slot is formed for the tuning screw, on which screw there is a collar, between which and the lever a washer is introduced. This arrangement suits upright pianofortes, but a modified arrangement is applicable for horizontal pianofortes. *Patent abandoned.*

1565. N. DEFRIES. *Improvements in apparatus for measuring gas.* Dated July 12, 1858.

To keep the water to a constant level in a gas-meter, there is a vessel containing an additional supply of water affixed to the meter, from which a pipe with a covering valve descends to facilitate the filling and refixing of the water-supply vessel to the gas-meter. The pipe of the supply vessel descends into a water chamber so that the water in the meter and the chamber will at all times stand at a like level. In the event of the water in the meter and chamber falling below the proper level, water will descend from the vessel containing the additional supply, provision being made for the passage of air from the outer atmosphere into such water vessel when the water falls too low; but the flow of air from the atmosphere into the additional water-supply vessel is shut off as soon as the proper water level is obtained in the meter. *Patent completed.*

1566. J. TAYLOR. *Improvements in the manufacture of blocks for the construction of sewers, drains, and arches.* Dated July 12, 1858.

Here blocks of clay or brick earth are produced by expressing through moulding dies of the following form:—The inner surface is concave, and the sides are inclined to correspond with the section of the circle it is intended to produce by a series of such blocks. The outer surface of each block is formed with a longitudinal rib. In using such a block to produce a section of a sewer, a mould such as is now employed is used; one of the blocks is introduced therein, then the mould is filled in with bricks, and cement run in. By these means the number and extent of joints interior of a sewer, &c., will be greatly reduced. *Patent abandoned.*

1567. T. EARNSHAW. *Improvements in the manufacture of night lights.* Dated July 12, 1858.

Here a stand is made for each night-light of plaster of Paris, on which it can safely be burned without the bottom of the night-light being immersed in water. *Patent completed.*

1568. E. CHARD. *Improvements in pianofortes.* Dated July 13, 1858.

This consists in communicating motion to the hammer direct from the key by a hinged lever sticker. Also to a mode of insulating the sounding board by suspending it direct from the springs or wires. *Patent abandoned.*

1569. J. WEBSTER. *An improved manufacture of certain kinds of metallic ingots.* Dated July 13, 1858.

Here the inventor makes a case or hollow ingot of the form it is intended the finished ingot shall have, the said hollow ingot being made of the metal it is intended the surface of the rolled plate shall have. The case is closed on all sides excepting one. He pours into the ingot through the open side the metal to form the interior of the plate. He then closes the opening with a piece of the same metal as the surface of the ingot. When rolled the plate of metal is coated entirely with the desired metal. *Patent abandoned.*

1570. J. A. FUSSELL. *A new or improved method of ornamenting chandeliers, pendants, and brackets for gas and other lamps, which method of ornamenting is also applicable to curtain bands.* Dated July 13, 1858.

This consists in applying small mirrors or pieces of looking glass to parts of chandeliers, pendants, &c., the said mirrors being inserted and fixed in a framing formed in the article, and defended at the back, so as to prevent any injury to the silvered surface. *Patent completed.*

1571. J. TRAVIS and T. and F. SUGDEN. *Certain improvements in lubricating the valves and pistons of steam engines.* Dated July 13, 1858.

The inventors use a vessel for holding a reserve of oil, &c., and to this vessel connect on the lower side a valve or tap made to slide, rotate, or reciprocate, by a connexion with some moving part of the engine, by the working of which valve or tap, the oil, &c., passes in small quantities, at given intervals, from the vessel, the valve or tap receiving the same and delivering it into the outlet pipe below. They connect the outlet pipe to the conduit pipe, whereby the steam is conveyed from the boiler to the engine, or to the steam passage of the valve box or boxes, so that the oil, &c., is partially vapourised, mingling with the current of steam, and is thereby carried along and deposited upon the valve facings and interior surface of the cylinder. *Patent abandoned.*

1572. J. EDWARDS and T. NEWEY. *Improvements in the manufacture of blind furniture.* Dated July 13, 1858.

This relates to a method of fastening the tassel cord to blinds. The patentees take a hollow acorn, or other design made of wood, bone, &c., made to unfasten in the middle by a screw, and having a hole made in one end to allow the tassel cord to be passed through, and a screw fixed into the other end whereby to fix it to the blind. The tassel cord is passed through the hole from the outside, and a knot tied in the end, which knot is then drawn inside. The design is then put together, the tassel cord being suspended from it. *Patent completed.*

1573. J. J. FIELD. *A new method of supporting and carrying telegraph wires, ropes, and cables.* Dated July 13, 1858.

This consists in supporting telegraph wires, ropes, and cables in the air by balloons or vessels containing light gaseous fluids. *Patent completed.*

1574. G. BUCHANAN. *Improvements in sugar-cane mills.* Dated July 13, 1858.

This relates to the construction of the standards or side-frames of sugar-cane mills for carrying the rollers; the mode of drawing out the lower rollers, the iron tie bars at the sides of the standards, the flanges at the ends of rollers, and other details not described apart from the drawings. *Patent completed.*

1575. A. SHANKS. *Improvements in machinery for planing, slotting, and shaping metals.* Dated July 13, 1858.

The inventor gives motion to the cutting tools by hydraulic appliances, in lieu of toothed gearing, cranks, racks, and screws. *Patent abandoned.*

1576. W. BEADON. *Improvements in the manufacture of bags for corn and other articles, and sails for ships.* Dated July 13, 1858.

This consists in combining metal wire with the yarn, &c., of which the bags, &c., are made. *Patent abandoned.*

1577. R. WILSON and A. HORWOOD. *An improved pipe joint.* Dated July 13, 1858.

Here the inventors insert the ends at the two pipes into an india-rubber tube, and on the outside of the tube they affix metal clips or clasps, and screw them with set screws to press the tube around the pipes. *Patent abandoned.*

1578. E. J. MAUMENE and L. B. JAUNAY. *An improved method of and apparatus for the production of sparkling wines.* Dated July 14, 1858.

Here the wine is placed in metallic vessels, where it remains while froth or effervescence takes place. *Patent abandoned.*

1579. C. DE POORTER. *Improvements in hand or power looms.* Dated July 14, 1858.

This consists; 1, in applying directly shuttle driving rods to power loom battens. 2. In a process for stretching out the warp and woven cloth on the hand or power looms by a contrivance the effect which is to maintain the warps in a regular tension during their unrolling from their beam, and to roll up with a like tension the cloth as it is woven, by yielding to the warp threads at the moment they open for the shuttle's passage. 3. In applying to hand or power looms several new processes, which allow weaving by merely raising and lowering many kinds of tissues which have been produced only on the old hand looms by using either cording, Jacquard apparatus, or drawing the blades by the help of a great many treadles. 4. In new processes for working or effecting the raising, lowering, or stoppage of the shuttle boxes, &c. 5. In applying a steady and motionless stretcher to any loom working with a regulator. 6. In transforming the old ribbon or lace loom into a new one, by doing away with all the partial warp or ribbon beams or rollers with their pulleys and counterpoises, and giving to such looms a single warp beam and a single cloth rolling beam as in common looms, and by subdividing the warp thread in a reed in as many portions as each ribbon is to contain of these threads, and applying the improved stretcher on both beams.

1580. W. WOODCOCK. *Certain improvements in apparatus for warming air.* Dated July 14, 1858.

This consists in casting pipes of metal, with wings radiating transversely from their outer surface, so as to cause a current of air, when such pipes and wings are heated, to pass upwards between the wings. *Patent completed.*

1581. R. BURNS and J. REA. *Improvements in machinery for grinding bones and other hard substances.* Dated July 14, 1858.

This refers to a previous patent of the patentee, and consists in relieving the cutting bar when interfered with by hard matters mixed with the substances to be cut; also in a peculiar mode of setting the knives in the cutting cylinders of bone machines. The invention is not described apart from the drawings. *Patent completed.*

1582. J. COWAN. *An improved screw-nail.* Dated July 14, 1858.

This refers to screw nails that may be driven into timber, &c., and withdrawn by a screw driver. *Patent abandoned.*

1583. F. CHAPUSOT and V. AVRIL. *Improvements in producing a more or less perfect vacuum, and applying the same to industrial purposes.* Dated July 14, 1858.

This invention is based on the equilibrium existing in a barometric tube between the chamber and a column of liquid. It consists in the use of a large barometric chamber, and filling the same with water or other liquid, then drawing off the liquid through an outlet pipe with stop cock, so as to produce a more or less perfect vacuum in the vessel. The same may be applied for emptying cesspools, cleaning harbours, and various other purposes. *Patent abandoned.*

1584. J. JONES. *Improvements in meters for measuring liquids.* Dated July 14, 1858.

Here the meter is so arranged that the valve, by which the flow of the liquid is governed, is caused to move by the re-action of the pressure of the liquid within either of the chambers when it is fitted on instruments in connection with the valve. *Patent completed.*

1585. E. OWEN. *Improvements in distilling.* Dated July 14, 1858.

This consists in submitting the body to be distilled when in a liquid condition, and in a state of minute division, to

Digitized by Google

the action of steam, or some heated gaseous vapour. *Patent completed.*

1586. T. WHEELER. *An improved combination of machinery for cutting, slicing, grating, and pulping turnips, mangold wurzel, and other roots.* Dated July 14, 1858.

This consists in casting suitable openings in a conical disc or discs set at any angle, or in flat discs or cylinders. To these apertures suitably shaped knives are fixed. The patentee uses a roller consisting of a worm or thread fixed upon a cone, and made at convenient angles, so as to work the conical disc. There are various modifications included. *Patent abandoned.*

1587. J. MACLEAN. *Improvements in machinery or apparatus for laying or submerging telegraph cables in water.* Dated July 14, 1858.

Here the cable is passed direct from the ordinary or any other paying-out apparatus. It is then passed beneath a grooved wheel carried by the deck of the vessel, and thence ascends over a grooved wheel on the top of a long vertical traversing shaft, the lower end of which is set in a vertical tube or guide carried by the vessel. This shaft and wheel is retained at its highest elevation by counterweights suspended from chains attached to the shaft at the top. It next passes beneath a second grooved wheel upon the deck, again rises and passes over the upper grooved wheel of another compensating weight and spring arrangement, then passes beneath another grooved wheel at or near the level of the vessel's deck, finally reaching the water at an angle of about 45 deg.

1588. T. WHEELER. *Improvements in washing, wringing, and mangling machines.* Dated July 14, 1858.

This invention was described and illustrated at page 90, No. 6, of the MECHANICS' MAGAZINE (New Series).

1589. H. W. WIMSHURST. *An improvement in store grates.* Dated July 14, 1858.

This consists in supplying a fire with fuel from a hopper under the fire. The fuel is forced upward into the centre of the fire, and the ashes find egress on each side. *Patent abandoned.*

1590. J. RHEINAUER. *Improvements in the bearings for axles and shafts in order to lubricate and exclude dust from such bearings.* (A communication.) Dated July 14, 1858.

The lubricating apparatus consists of a piece of wood placed in an oil vessel under the axle, &c., within the bearing, and the upper surface of this piece of wood is caused to press against the axle, &c., by springs. Over the lubricating block, which is grooved to receive it, a wick of felt, &c., is laid, and its two ends descend into the oil, the oil being sucked up by the wick and applied to the axle, &c. The bottom of the groove in the lubricating block is furrowed to assist the transmission of the oil to every part of the wick. The apparatus for the exclusion of dust is specially applicable to the bearings of railway carriages, and consists of a ring of felt, &c., enclosed between two metal rings attached to the end of the bearing; the axle passes through the rings, and dust is thereby excluded. The lubricating apparatus is modified according to the purpose to which it is applied. *Patent completed.*

1591. J. FOWLER, JUN. *Improvements in apparatus used when ploughing, tilling, or cultivating land by steam power.* Dated July 14, 1858.

This consists, 1, in a method of combining winding capstans or drums with portable steam engines. 2, in apparatus for taking up the slack of the rope behind the implement. *Patent completed.*

1592. C. W. WILLIAMS. *Improvements in locomotive and other boilers for giving them increased power in generating steam.* Dated July 15, 1858.

This consists of certain arrangements for causing the heated products of combustion passing through the flues or tubes to be changed from their direct onward course, and to take an oblique one, thereby occasioning an action more impinging on the interior surface of the tubes or flues, by which more heat will be passed to the water. *Patent completed.*

1593. R. BRAZIER. *Improvements in repeating fire-arms.* Dated July 15, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1594. J. ASHMAN. *Improvements in artificial legs and arms.* Dated July 15, 1858.

This relates to constructing artificial limbs of textile fabric cemented by glue, &c., and covering certain portions of such limbs with animal skin, to give to such parts the appearance of natural skin; also to means of actuating the joints. Provisional protection has not been granted to the inventor. *Patent abandoned.*

1595. C. P. ASTON. *Improvements in breech-loading arms.* Dated July 15, 1858.

This consists in forming a cup-like seat in the breech to receive the rear end of the barrel or barrels. He causes the barrel to slide to and fro in a direct line with the breech, and prefers to form the percussioning in the breech. *Patent completed.*

1596. W. A. GILBEE. *Improvements in the mode of covering cotton, woollen, and other thread with silk, and in the apparatus connected therewith.* Dated July 15, 1858.

Here the cocoons are placed in a vessel containing water and wind round a thread of cotton, &c., from a bobbin in front of the vessel; the thread enters the water and passes out through the cocoons, being guided by an iron wire placed transversely in the water, where it forms a hook at the required part to keep the thread perpendicular with an eye in a suitable plate or stem. When the cotton thread has been joined by the cocoon thread it passes through a hole or eye, and at the same time rolls over a spindle receiving a rotary motion round itself. This motion is obtained by a hollow cylinder put in motion by a strap or band. *Patent abandoned.*

1597. H. BEVAN. *A new or improved machine for effecting or facilitating arithmetical operations.* Dated July 15, 1858.

This consists of a series of strips of metal, each strip having marked upon it two vertical rows of figures separated by a broad line. Each row is divided by a horizontal division into groups, such group consisting of ten. There are as many groups as there are places of figures in the multiplier; that is, one group for the units in the multiplier, another group for the tens, and so on. *Patent abandoned.*

1598. A. H. J. BASTABLE. *Improvements in apparatus employed in the production of light.* (A communication.) Dated July 15, 1858.

This invention consists in protecting the cylinder of lime, &c., (used for producing light by throwing a jet of gas, &c., thereon) by a metal case. The cylinder projects upward beyond the end of the case, and the jet strikes the portion of the cylinder above the case. *Patent abandoned.*

1599. T. BARTLETT. *Improvements in stoves, fire-places, and furnaces.* Dated July 15, 1858.

Here the fire is lighted in an upper compartment, and a portion of the grate, with one or more of the fire-bars, is opened, and coal is supplied to a lower compartment, which will progressively become ignited. The gases and products therefrom will rise up through the well-ignited fuel in the upper compartment of the stove, and be burned. *Patent completed.*

1600. P. FAIRBAIRN. *An improvement in lathes.* (A communication.) Dated July 15, 1858.

This relates to "dead centre lathes," and consists in fitting to the front of the driving head dead centre a seat to receive change brushes or bearings capable of being used as a fixed support for the outside journals of the axle of the article to be turned. The axle being thus supported it will be free to revolve. The article itself is to be driven at its circumference from the face plate by a pin, element driver, &c. The driver can turn round without interfering with the axle carrier. *Patent abandoned.*

1601. W. E. NEWTON. *An improved mode of giving alarm in cases of fire in houses, ships, or other buildings.* (A communication.) Dated July 15, 1858.

This consists in attaching combustible threads to grenades, suitably placed so that on the threads taking fire an alarm will be given by the explosion of the grenades. The threads are to be protected from damp by enclosing them in tubes of gutta percha, &c., perforated with small holes to facilitate the combustion of the threads. *Patent abandoned.*

1602. W. BETTS. *Improvements in the manufacture of capsules, and in the apparatus to be employed therein.* Dated July 15, 1858.

Here the inventor takes a mould having on it a male screw formed on the neck of the bottle to which the capsule is to be applied; the capsule being placed on this screw-mould, the mould and capsule are rotated and moved in a lateral; a small disc is then pressed against the capsule, which forces it into the indentations of the screw-mould, and at the same time embosses the raised portions of the screw, and a stiff screw capsule is produced. *Patent abandoned.*

1603. T. LEIGH. *Improvements in machinery or apparatus for sizing warps.* Dated July 16, 1858.

This consists in applying to the ordinary sizing machines or tape lers one or more steam chests for drying the warps. *Patent completed.*

1604. F. PRIESTLEY. *Improvements in condensing steam engines.* Dated July 16, 1858.

This consists in drawing off the condensed water and air from the condensor by creating a vacuum in the air-pump, barrel, or cylinder without any piston, or in a suitable closed vessel, by the alternate admission and condensation of steam. The water when drawn from the condenser, and that formed by the condensation of the steam in the vessel itself is blown through, the same by the steam, and the steam and cold water for condensation are alternately admitted by suitable valves, whereby the air-pump and piston-rod, and the crank for working the same, are dispensed with, and a saving of power and cost, and of space occupied, thereby effected. *Patent abandoned.*

1605. C. DE BERGUE. *Improvements in submarine telegraph cables, for submarine purposes; and in the machinery for manufacturing such cables; and also in the machinery to be used in paying such cables out of ships at sea.* Dated July 16, 1858.

This invention was described and illustrated at page 157, No. 10, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1606. M. VOSS. *Safely submerging ocean telegraph cables and other heavy bodies in rivers, lakes, and seas, by means of inflated buoys and connecting gear.* Dated July 16, 1858.

Here the submersion of the cable is effected by buoys or air-cases, for the temporary suspension of portions of the line. *Patent abandoned.*

1607. P. ARKELL and A. MELHADO. *Improvements in the submerging of telegraph cables.* Dated July 16, 1858.

This invention was described and illustrated at page 157, No. 10 of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

1608. A. P. PRICE. *Improvements in the treatment and smelting of certain ores or compounds of tin, and of tin, and of certain alloys thereof.* Dated July 16, 1858.

This invention consists chiefly in employing carbonaceous or bituminous matter for the above purposes. *Patent completed.*

1609. C. S. PUTNAM. *An improvement or improvements in the apparatus for hardening vegetable gums, oils, and other substances susceptible of being hardened by steam.* Dated July 16, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1610. T. F. CHORLEY. *Improving the form of banker's cheques and other similar documents, with the view of preventing fraudulent dealings therewith.* Dated July 16, 1858.

This consists in printing on banker's cheques, &c., the words "uncrossed cheque," which are to be torn off if the cheque is passed through a bank, and left on if payable to bearer. *Patent abandoned.*

1611. W. A. B. BUSSETT. *Improvements in military capes or cloaks.* Dated July 16, 1858.

The capes are so formed that several may be combined and form a tent. *Patent completed.*

1612. T. HART. *Improvements in taps or cakes, and in apparatus for regulating the flow of fluids.* Dated July 17, 1858.

This relates to a patent granted to G. Buchanan, 3 Dec., 1850, and is not described apart from the drawings. *Patent completed.*

1613. J. SPENCE. *An improvement in the manufacture of tin plates and terne or leaded plates.* Dated July 17, 1858.

This consists in manufacturing such plates from sheets of steel, iron, or puddle steel and coating them with tin or alloy. The said sheets are rolled from a finished piece or bar, or from a piece of the puddled bar in its first stage of manufacture. *Patent completed.*

1614. J. T. SMITH. *A new or improved manufacture of coke.* Dated July 17, 1858.

This consists in mixing small coal with tar and setting fire to it in the open air or in a retort. *Patent abandoned.*

1615. W. WILDES. *An improved arrangement or arrangements of machinery for reducing vegetable matter to pulp.* Dated July 17, 1858.

This consists in driving rolls or cylinders at different speeds, or in driving rolls or cylinders of unequal diameters at the same speed. *Patent completed.*

1616. R. A. BROOMAN. *Improvements in apparatus for the reception of fecal and sewage matters, and in the treatment of fecal matters.* (A communication.) Dated July 17, 1858.

This consists in collecting the sewage, &c., in a suitable vessel, causing the precipitation therein of all solid matter, treating such solid matter with sulphate of lime, working it up in a brick machine, drying it and reducing it to powder to be used as manure. *Patent abandoned.*

1617. W. PIDDING. *Improvements in securing and forming envelopes.* Dated July 17, 1858.

Here the inventor seals with wax the outside of the ends of the tongues of envelopes without connecting them by the wax with the remaining portion of the envelopes. He also forms envelopes of two or more pieces of paper so that waste paper may be used in their manufacture. *Patent abandoned.*

1618. W. A. LLOYD and E. EDWARDS. *Improvements in aquaria tanks and similar receptacles for aquatic animals and plants.* Dated July 17, 1858.

These tanks are formed with a dark chamber, which is not intended to contain animals or plants, but the fluid it contains communicates with the fluid in the space holding the animals and plants. *Patent completed.*

1619. J. J. DESMARES. *A new process for oiling wools.* Dated July 19, 1858.

This consists in combining with a given weight of pure olive oil one-fifteenth part of liquor ammonia, and oiling the wools with this compound. *Patent abandoned.*

1620. C. F. VASSEROT. *An improved artificial manure.* (A communication.) Dated July 19, 1858.

This manure is composed of straw, green forages, such as trefoil, peas, &c., lime, salt, and water. *Patent abandoned.*

1621. C. BRAY. *Improvements in ice safes.* Dated July 19, 1858.

The outer case of this safe is made of wood, lined with felt, and closed by a cover. This outer case contains another case of wood, lined with metal, also closed by a cover. In the upper part of this inner case there is a metal box for ice. This box is perforated at bottom, and has a cover. Underneath this ice box are several metal cylinders for bottles of wine, &c., over which the water which drains from the ice trickles. The ends of the cylinders pass through to the outer case, and are each closed separately. The series of cylinders is closed in by a hinged flap on the outer case. Against one side of the box is a metal cistern for water, and in the other are shelves for articles to be cooled. *Patent abandoned.*

1622. H. SMITH. *An improvement or improvements in the manufacture of harrows.* Dated July 19, 1858.

The patentee claims, 1, joining the bars constituting the frame of the harrow, by hollow bolts passed through holes at the crossings in the bars, the protruding ends of the bolts being expanded and riveted upon a collar or washer previously placed upon the hollow rivets, the hollow rivets, in addition to joining the bars of the harrow, containing the holes in which the tines or tangs are fixed. 2. In fixing the tines or tangs in harrows, by forcing them either by percussion or by pressure into taper holes formed in the hollow bolts by which the framing of the harrow is held together. *Patent completed.*

1623. C. REEVES. *Improvements in repeating fire-arms.* Dated July 19, 1858.

The patentee claims, 1, the mechanism for raising the hammer or cock, and liberating the raised hammer or cock by pressure upon the trigger, and the mechanism for holding the hammer or cock at half and full cock, and of liberating the cocked hammer when the said hammer has been cocked by pressure upon the comb of the hammer. 2. The method of constructing and fixing the axis on which the revolving barrel of a repeating fire-arm rotates, by making the axis a quick threaded screw engaging in the anterior part of the frame in which the revolving chamber works, so as to advance or recede in the frame when the axis is made to rotate. *Patent completed.*

1624. T. GREENWOOD, J. BATLEY, and J. SALT. *Improved machinery for preparing silk to be spun.* Dated July 19, 1858.

This relates to machinery for opening the cocoons or waste silk, and consists in the use of two opening cylinders and of a machine denominated the "separating spreader." The silk is fed to this machine by the feed cloths or bands. *Patent completed.*

1625. J. W. WILSON. *An improved preparation of materials to be used for roofs and other parts of buildings, and for various purposes for which wood is now generally employed.* Dated July 19, 1858.

This consists in combining together, by some adhesive material, shavings or thin sheets of wood arranged in layers one above another. These sheets are to be corrugated by corrugated rollers. *Patent abandoned.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MARCH 18, 1859.

THE SHIPS OF THE ROYAL NAVY.

WHETHER Lord CLARENCE PAGET is really anxious for the truth, or whether a seat at the Board of Admiralty would be much more likely to satisfy him, it is not for us to inquire; but it *is* for us to assert that the course which he is pursuing will lead him far more surely to the latter than to the former. Lord as he is, and acquainted as he ought to be with what is just and honourable, he has yet to learn that errors, perversions, and misrepresentations are disgraceful weapons in the hands of public men.

It is, and has long been, perfectly manifest to us that the greatest enemies to our administrative reforms are the men who incautiously and inconsiderately attack our administrative departments. Their broad and sweeping charges excite public indignation, only that it may be baulked by official justifications. Thus the true friends of reform are trifled with, and their hope of useful change is perpetually destroyed.

We shall not now follow Lord PAGET through those figures of his which no one can either contradict or verify without access to information not yet published. Indeed, we shall not even enter upon the question of the cost of ships at all, because in the Department of the Surveyor of the Navy a return is now being prepared for the House of Commons which will settle that question much more completely than we could possibly do. We will merely advert, and that briefly, to those portions of his lordship's speech which referred to what he was pleased to call "the reckless alterations of new ships;" and that we may not misrepresent him, we will quote his words as reported in the leading journal. He said:—

"Almost every ship was altered. Take the case of a three-decker, the *Howe*, 121 guns. She was laid down only last year or the winter before, but the dockyard people were now pulling her down to put a new bow upon her. Had any great improvement been made in the bows of ships within the last two years? Nothing of the kind had taken place. Another case was that of the *Immortalité*, a 51-gun frigate, now being built at Pembroke. That unfortunate ship had gone through a great deal of trouble. She was first of all lengthened amidships. Last year, orders went down from the Admiralty to lengthen her five feet by the bow. Certain parties—he did not know who, but he had no doubt persons at Pembroke—thought that to lengthen a frigate five feet by the bow would be to make an imperceptible alteration, and would have no effect whatever. We lengthened yachts 14 or 20 feet by the bow. But the authorities were inexorable, their orders were reiterated, and the poor ship was lengthened five feet by the bow. The result was, as might be naturally supposed, that either the First Lord himself, with his fine nautical eye, or some other member of the Admiralty Board, saw upon visiting her that she was not fit to go to sea, and ordered her to be pulled down again and lengthened 15 feet. Such instances of official blundering would be amusing if they were not so costly. The *Orlando*, the *Mersey*, and, indeed, almost all that class of ships, had been treated in a similar manner; but, not to detain the House, he would now ask their attention to a case which was almost incredible. Some time ago a frigate, the *San Fiorenzo*, was being built either at Deptford or Woolwich. She was a great favourite with the London folks, who used to visit her in large numbers, and a beautiful model she was.

Sir J. PAKINGTON.—Where is she now?

Lord C. PAGET.—The First Lord asked where she was now. Why, she had vanished into thin air—gone, he hoped, to another and a better world. (Great laughter.) He would not trouble the House with any more of these cases. The *Lyra*, the *Racer*, and other noble vessels began life at 450 tons, but they gradually grew in size until they arrived at 750 tons, when they were launched. Was not that a reckless expenditure of money?"

Now, let us consider the facts of each of the cases here adduced in the order in which the vessels are named—the *Howe*, the *Immortalité*, the *Orlando*, the *Mersey*, the *San Fiorenzo*, the *Lyra*, and the *Racer*; and in doing so, it is absolutely essential to remember that we are dealing with a period when the introduction of steam has been imperatively demanding the "re-construction" of such vessels as were originally designed and laid down as sailing ships. Of the first case adduced—that of the *Howe*—we have but little to say, because it happens that the alteration to which she has been subjected was never altogether approved by ourselves. That alteration, however, in the vessel has by no means involved the "pulling down" of the ship, as Lord PAGET implies. And if no great improvement has been made in the bows of ships during the last two years, facts have been observed which induced the Admiralty to consider a further increase in the fineness of the bows of our large screw ships desirable; and it was in consequence of this, and not from mere wantonness, of course, that the change in the bow of the *Howe* is being made. For the lengthening of the bow of the *Immortalité*, Sir CHARLES WOOD was responsible, and has since made in the House of Commons the following statement respecting it:—"The fact is," he says, "the ship was in frame, and it was only necessary for the purposes of the alteration that a few bolts should be removed; the whole of the extra expense being the mere cost of additional labour. I may add that the reason why the change was made was to secure the advantage of her having fine lines at the bow." This statement is, we can assure our readers, perfectly true, and we need only add that the first lengthening of the ship amidships was absolutely essential to her conversion from a sailing ship into a screw. With regard to the *Orlando* and the *Mersey*, we have only to offer an unqualified contradiction to Lord PAGET'S assertion. These vessels have never been lengthened or interfered with in any such way since their keels were first laid. The *San Fiorenzo*, or as much as ever existed of her, "vanished" certainly, but not, we fear, into either another or a better world. The facts respecting this ship are very simple. Before the use of the screw became general, she was laid down at Woolwich as a sailing frigate 188 ft. 9 in. long. After she had been put into frame, and before her planking was nearly completed, it was proved advisable to discontinue building sailing ships of war. In order to convert her into an efficient screw ship, it would have been absolutely necessary to lengthen her nearly 50 ft.—46 ft. 3 in. was the additional length decided upon. But unfortunately the slip at Woolwich would not admit of the extra length being added, and from the extreme narrowness of that dockyard at the building end of it, the slip itself could not be lengthened. In most dockyards the fore end of a slip might be carried forward without difficulty, but the Woolwich slip was already within a few feet of the dockyard wall, and the wall itself is all but touched by the houses of the town. The projection of a slip 50 ft. into the Thames for a considerable period was, of course, altogether impracticable. The only course left, therefore, was to take down the frame of the ship, and apply its timbers in the construction of some other vessel; and this is what was done. That those timbers afterwards served under another name than *San Fiorenzo*, can scarcely, we presume, be deemed a calamity. So much for the "case which was almost incredible."

It only remains for us to notice what was said of the *Lyra* and the *Racer*. Of this portion of Lord CLARENCE PAGET'S speech we have scarcely patience to speak. Will it be believed that all he said about these noble vessels beginning life, and gradually growing in size from 450 to 750 tons, was based upon the simple fact that the names *Lyra* and *Racer* were first appropriated *on paper* to vessels of one class, and that it was afterwards found convenient to transfer those *names* to vessels of a larger class? The vessels *Lyra* and *Racer* themselves have undergone no kind of alteration whatever.

Now, we put it to any honest, any candid, any sensible man whether, with these facts before us, we have not a right to ask if it is sheer incapacity, or wanton mischievousness, or something worse than either, that is at the bottom of those remarks of Lord PAGET'S which we have quoted? As to the expectation of any public advantage arising from his speech, we should almost feel disposed to spurn any benefit which was obtained for us by a speech so false, or by a man so extravagant. The truth appears to us to be that Lord PAGET has been whispering with dockyard men and officers, and seeking from them the materials for an attack upon the Admiralty. Information thus obtained would be very useful to a man who knew how to estimate it—how to discriminate between what was worthy of regard and what was the mere prejudice of men some of whom are but too willing to play the critic over matters which they but imperfectly comprehend. But for a man who is at once a Member of Parliament, a Lord, and an Admiral, to gather statements from such sources, and then to gravely reproduce them, in the hearing of the entire world, as facts which deserve to be implicitly credited, and which should induce immediate administrative changes—this, we say, is to abuse the privileges with which he is endowed by each and all of his high offices.

It would not be easy to calculate the mischief which has been wrought by the speech upon which we are commenting. There is not one of the noble lord's charges which has not been, or will not speedily be triumphantly replied to, and there the matter will end. And yet, is it to be for a single moment supposed that no evils, no errors exist in the administration of our dockyard affairs? Not by us, certainly, nor, we presume, by many others. But the vital evils which do exist Lord PAGET has passed silently by, and has expended all his remonstrances upon errors and absurdities of his own. And so, we fear, on naval affairs the public interest will for a long time to come continue to be to a certain extent sacrificed. The first essential of any reform of those affairs from without is, that they shall be taken up by a man who will have the patience to discover the truth, the courage to adhere to it, and the manliness to scorn the use of such weapons as Lord PAGET delights, apparently, to wield.

In the debate on the speech in question, Mr. CORRY reverted to a matter which we should not fail to notice here. Last year Lord PAGET furnished the Admiralty with the design of a frigate which was to prove infinitely superior to the vessels designed by the Surveyor of the Navy. We lost no time, as our readers will recollect, in showing how sad a blunder his lordship had made in his calculations. Mr. CORRY, on Friday last, told us that his lordship's design was referred to the Surveyor of the Navy, who sent in the following report on it:—

"From the above estimate it appears that the displacement is too small by 615 tons. Hence the ship would be immersed two feet beyond the draught of water given, and the greatest transverse section would be increased from 645 square feet to 720; and that when all the guns, as was intended, were fought on one side, the inclination of the ship would leave only 4 feet 3 inches for the height of the midship port in smooth water, and that to carry, as proposed, 1,000

Digitized by Google

tons of coals, it would be necessary to stow 600 tons on the lower deck."

And this brings us to notice the principal feature of last Friday's debate—viz., the unanimity with which the reputation of the Surveyor of the Navy was supported by many of the most distinguished speakers. To say that Lord PAGET'S speech was not an attack upon Sir BALDWIN WALKER is to talk nonsense. Had Lord PAGET taken the trouble to ascertain where the Surveyor's duties ended, and to have shown to how great an extent that officer's wishes and intentions are at times interfered with by shifting Boards of Admiralty, there might have been room to doubt his hostility to the Surveyor. But as it was, he permitted the full weight of his strictures to fall upon the Surveyor. And this we deem the worst feature of the whole affair; because, Sir BALDWIN WALKER has really managed the navy with unexampled judgment. We are quite aware that he has been most efficiently and constantly aided by a scientific staff of naval architects whose equals as a body are nowhere to be found out of the Government service. None would, we believe, assert this more cordially than the Surveyor himself. And herein lies one of his greatest merits. Instead of thinking lightly of, and disregarding the counsels of his scientific assistants, and enforcing crotchets of his own in place of their science—as ninety-nine admirals out of a hundred would have done—he has given full scope to the skill of those gentlemen, and has anxiously supplemented it by his own great knowledge and experience as a seaman. The consequence is, we have a navy which, whatever defects it may possess, is superior to all the navies of the world—a navy which is, as we have before said, and as Sir CHARLES WOOD repeated on Friday last, "the embodiment of all such sound and well-tested improvements as have hitherto been found compatible with the purposes for which ships of war are designed." And we say unhesitatingly that the man who, in the face of these facts, could permit himself to speak in public as Lord PAGET spoke on Friday last, deserves either the contempt or the pity rather than the approval of his country. This we say without wishing to deprecate any criticism which is just and instructive. On the contrary, we admit that evils exist, and we shall probably take an early opportunity of pointing out the nature of some, at least, of them.

THE TUBAL CAIN OF OUR COUNTRY.

IN the busiest streets of London we often meet a man whom we never see without blushing for our country. Had English statesmen been pure, that man would have been a millionaire; had they been wise, he would have been a peer of the realm. As it is, he lives in a single room, and is sometimes sorely troubled to retain even that. At the age of seventy-five, he has still to seek his daily bread, and is but barely saved from receiving it from the hand of charity. Hidden in obscure corners of the kingdom are three sisters of his, even more aged, and still poorer than himself. Yet the father of that hapless family gave untold millions to England, and contributed more than any other man to that material progress by which she gained, and still keeps, her pre-eminence. The aged son who still survives is RICHARD CORT, of Islington—the father was HENRY CORT, whom the first journal of the world lately named the Father of the British Iron Trade, and the Tubul Cain of our country.

It is no exaggeration to say that the inventions of HENRY CORT were the main agents by which the marvellous physical progress of this country has been attained. Before those inventions were introduced, Great Britain was mainly dependent upon foreign countries for its iron. Had our dependence continued, how would it have been possible for us to have entered upon any one even of the great works of modern times—such as the construction of steam engines, the replacement of hand manufactures by machinery, and the formation of railroads, electric telegraphs, iron ships, iron bridges, and iron buildings? It would manifestly have been impossible. But with the inventions of CORT came our emancipation. He taught us how to use the treasures of our own land for our own purposes, and how, thereby, to carry our useful arts far in advance of all that had ever been imagined. No doubt exists on this point. It has been openly attested by hundreds of the most eminent engineers, manufacturers, and men of science in the kingdom; Members of Parliament by scores have cordially acknowledged it; Cabinet Ministers have not hesitated to admit it; even the Queen has openly recognised it. Yet the aged family of this man are still permitted to creep on to the tomb, not utterly penniless and pensionless, it is true, but with only just sufficient crumbs from the tables of this opulent nation to keep them alive, and thus to prolong their poverty and shame.

Three years ago the total make of rolled iron produced by CORT'S machinery was computed at thirty millions of tons; and the saving to the consumers of iron as compared with the previous cost of foreign iron, averaging £20 per ton, has been computed by one of the most experienced and impartial judges, Mr. W. FAIRBAIRN, at SIX HUNDRED MILLIONS STERLING. This sum is represented as the pecuniary value of HENRY CORT'S inventions to the British nation in a memorial to Viscount PALMERSTON, presented by Lord STANLEY in 1857. The same memorial was strongly recommended by Lord STANLEY to the Earl of DERBY in 1858, signed by many of the most eminent scientific, practical, and parliamentary authorities, including two Cabinet Ministers. When a man is known to have directly enriched his country by six hundred millions of money, it becomes unnecessary to inquire in what other ways he has done it service. And in this case it would be absolutely impossible to measure, or even to trace, the innumerable services which one man has indirectly rendered us. Wherever wrought iron, in any form whatever, is used by us, there we are indebted to him; for his inventions have never yet been superseded. Nor can the full extent of the nation's debt to the CORT family be at all understood until it is known that HENRY CORT himself was not only unremunerated, but also robbed of a small private fortune and the whole of his patent property by Government officials, with whom, in his dealings with the Navy Board, he became associated. The great services which he rendered to the Royal Navy were rewarded by total ruin.

In return for all his inventions, labours, wrongs, and sufferings, and in consideration of the £200,000 of which he was defrauded, HENRY CORT'S widow and children have during the last seventy years received from the Government some two or three thousand pounds. The sums subscribed during the same long period by iron manufacturers, most of whom have made their fortunes by means of his inventions, fall considerably short of £2,000. Altogether the family has had less than £5,000. And even this sum has been received and expended in inconsiderable items, chiefly in the shape of pensions, which we are positively ashamed to mention in detail. And now, in their extreme old age, they are left to struggle on with the bare means of subsistence only—the son without even them, for he has had to sacrifice even this small pension in his efforts to obtain justice for himself and his sisters.

Now, we ask if the present condition of this family is not a great disgrace to us? Not to the press certainly; for, from the *Times* downwards, every newspaper in the land has done its best to serve them. But is it not a disgrace to the nation? And especially is it not a disgrace to those who, by a little self-devotion and energy, might have had justice done? Many have *promised* to aid in securing some suitable provision for the family. Lord STANLEY excited great hopes in this manner: but the cares of an empire in India have left him no opportunity for seeking justice, even for the family of the man who helped so much to make the British Empire what it now is. Mr. DISRAELI also undertook to consider the matter when he entered upon his present duties. Mr. ROEBUCK likewise commenced with energy the generous work of bringing the facts before Parliament; and when we remember what interests he represents—and still more, when we remember that he is the representative of that illustrious man, Dr. ROEBUCK, whose scientific labours so greatly aided the renowned WATT—we know not where to look for a person who could more fitly undertake such a work. Further, Lord PALMERSTON and Lord DERBY each promised to afford something more than temporary relief to the family. But, after all, nothing worthy of the circumstances has yet been seriously attempted.

It is not our desire, simply because we represent mechanical interests, to treat great questions with partiality, or to depreciate the claims of what are called "the professions." But we confess that we see something ominous in the fact that while soldiers, and sailors, and lawyers, and clergymen, are perpetually enriched and ennobled for very moderate services, no riches and no honours—nay, not even the common necessaries of life—are bestowed upon many inventors, nor even upon this family of one of the greatest inventors that God ever gave to this nation. Her Majesty has, it is true, conferred knighthood upon the inventor of a gun, and Ministers have added to the dignity a pleasant appointment; but a case or two of this kind cannot redeem our honour all the time we trample without pity upon the son and daughters of a man without whose inventions we could have had neither the arts nor the manufactures, neither the fleets nor the armies that now belong to us.

Is there no man, in or out of Parliament, who will take the matter up, and heartily endeavour to wipe away the stain of this dishonour? Casual and momentary aid is not all that is needed. There has been much of that afforded already. Ironmasters and engineers have subscribed trifling sums abundantly; Members of Parliament and Cabinet Ministers have given their good words to the cause; and Prime Ministers have contributed donations from the Royal Bounty Fund. But the wrong, and the suffering, and the shame, still endure. What is needed is the personal action of some man or men of influence, first to decide upon what ought to be done for this family, to the head of which we owe so much, and next to assume the responsibility of getting it effected. We sincerely hope that all the liberality of the nation will not be expended upon foreign exiles, and that while so many are turning philanthropists, some, at least, will not cease to be patriots. We do trust history will not have to record that, at the moment when our iron manufacture was most enriching us, and was even adding to our innumerable benefits that of a fleet of impregnable war-ships, the son and daughters of the

Digitized by Google

man who created that manufacture died neglected, indigent, and broken-hearted in our midst.

THE SHIPPING INTEREST.

The motion of Mr. Lindsay for a committee of the House of Commons to inquire into the burdens that press upon the shipping interest having been granted, this important subject will now receive the careful investigation which the considerations involved in it demand. Common justice requires that the British shipowner should be fairly dealt with by his countrymen, and in return they have a right to a "reciprocity" of regard—to use the phraseology of the shipowners—from him.

The complaints of the shipowners against unjust exactions (for we can give no milder appellation to processes by which the shipowner is mulcted for the lighting, paving, aye, and beautifying the streets of a town which derives its wealth and status solely from his patronage and enterprise), have but to be dispassionately represented to the country to insure a remedy. The general sense of the House of Commons will be too powerful for the opposition of such members as hold their seats on the "Lever principle" of *aut* Galway *aut nihil*," and who go to Parliament avowedly pledged to vote against everything that in any way touches the selfish interests of their local constituency. But if such points are conceded in justice to the shipowners, other demands, for exclusively protective privileges as opposed to the public good, must be as firmly resisted. The rights of property being respected, its obligations must not be forgotten, and we cannot shut our eyes to the evident purport of Mr. Crauford's speech, and one of the great objects in view in obtaining a revision of the various passenger and shipping acts at present in existence, viz., the limiting of the liability of owners to damages for loss of life, for which, as carriers of passengers by sea, they are (under Lord Campbell's Act) equally amenable with carriers of passengers on land. We cannot forget how perseveringly they have brought their influences to bear on the Board of Trade, with the proposed object of doing away with, or limiting by the merest consideration, this liability; but, thanks to the firmness of that department of the Government, their importunities on this point have been uniformly unsuccessful. It is true shipowners occasionally advanced in support of their pretensions for exemption their want of control over their servants when away at sea, and the hardship of making the owners the sufferers when accidents arise through their servants' carelessness under such circumstances. But what servant can be held to be under the control of his employer when once out of his sight? By the same rule the railway proprietor should be held harmless. And while asking for protection against the consequences of the negligence of their servants, can they show that they themselves conform even to the salutary regulations that the Government have been compelled from time to time to make compulsory on them, by legal enactment, with a view to guard the public against the consequences of the owners' neglect of the most obvious and necessary appliances on shipboard for the safety of life? Do not their very servants make public complaint of such neglect in respect of themselves, and are not many of the precautions that every feeling of humanity would suggest for ensuring the preservation of human life, and which the constantly-recurring liability to accident at sea renders imperative, not only entirely disregarded in scores of instances, but knowingly and wantonly withheld for the sake of the saving of a few pounds? In the important provision of boat accommodation, how do matters stand? By Act of Parliament, under fines and penalties (see Passenger Act, 1855, clause 27, which is seldom, if ever, enforced by the Government Officers when infringed), owners are compelled to make some provision in this respect; but the inefficiency of boats in equipment, condition, and capacity of accommodation, is generally the first theme for reprehension that the press have to descant upon when recording any serious desaster to the passengers of a ship at sea. Who can forget the *Amazon*, the *Birkenhead*, the *Victoria*, the *Arctic*, or later, the *Austria*? Scarcely a boat could be lowered to save from death the affrighted hundreds who vainly sought such a refuge. What would be the position in a court of law of any railway company through whose wanton neglect of an efficient code of signals or effective breaks, life had been thus sacrificed? And what Utopian board of directors would ever hope to pass an Act of Parliament by which, in the event of loss of life through accident to the train, the pecuniary compensation to the sufferers should bear a proportion to the value of such train—which is perfectly analagous to what shipowners require when they ask that their liability should be compassed by the value of the ship and cargo? Proof that they had complied with the requirements of the law made and provided, and that they had employed careful and efficient servants, would be their best, and, we imagine, only argument in extenuation of damages; and till shipowners can use the same, they are in justice liable to the consequences of neglect.

Pecuniary damages have conduced more than anything besides to greater care and improved management on railways, and a consequent diminution of loss of life; and when the pockets of owners are made to suffer for faults of a like nature, we may expect a better state of things. In self-defence they will impress on their captains and officers *their criminal responsibility* in the event of their failing in their duty to keep in proper order and make available their life-saving appliances; or, if need be, summarily to punish them for neglect. When human ingenuity was unable to suggest remedies in mitigation of human sufferings at sea, it was a different matter; but now that the value of the life-boat is known, and the safety with which it may be launched is an established fact, surely no ship whatever ought to be allowed to put to sea without a "Standard Life-Boat," fitted with an efficient means of lowering it; and we hope to see not only a clause to this effect inserted in any new act, but to see it, when it becomes the law of the land, rigidly enforced for the good of the community.

But the shipowners ought not in justice to be singled out as the only class on whom the obloquy of wanton indifference to life at sea rests. The Admiralty authorities and the officers of the royal navy must bear their share. Till the last year or so no provision was ever thought of in any of Her Majesty's ships for mitigating known and acknowledged causes of casualty amongst the men. The seaman who fell overboard when the ship was under weigh, *might* have a chance of being saved if he could swim well enough to keep himself afloat until the ship was "rounded to" (a work of some twenty minutes), when a boat could be lowered by the old tackles to pick him up; and of the sad exceptions such instances formed to the aggregate numbers of the lost, the recollection of every naval officer of experience in the service must be painfully sensible. How often, too, was the loss of the "man overboard" accompanied by fatal results to those who bravely attempted the rescue, solely through the faulty machinery they had to handle? Even now, after the strongest evidence of some of their most efficient officers, and their public recommendation that a remedy might and ought to be generally applied throughout the service for this evil, only a partial application of anything of the kind has been made in the Royal Navy, although some departments of the Government—the East India Board, the Emigration Commissioners, and the Transport and Convict Services—compel every ship that falls under their supervision to carry *two* lifeboats ready fitted for instantly lowering them on an emergency. Thus we have this strange anomaly—that while the House of Commons has legislated for a public requirement at the instigation of one branch of the Government, another department, and that the very one to which we look for a precedent in such matters, neglects to comply with its provisos, or only does so to a limited extent. Such an exception helps materially to retard the progress of a public movement, meant solely for the public good, and we sincerely hope it is but temporary.

As a corroboration to our present arguments we would refer to a letter on this subject that appeared a few days since in the *Times*, from Mr. Clifford, which goes far to prove what we have advanced. From that document we extract the following paragraph of a letter addressed by Captain Castle, of the *Sarah Sands*, to Mr. Clifford, which paragraph affords us great encouragement to insist upon the views we have stated above. This truly gallant officer says:—

"In reply to your inquiries as to the use made of your boat-lowering apparatus (fitted by order of the Government) in the steam transport *Sarah Sands*, I am happy to tell you that, immediately after the discovery of the ship being on fire, the ladies and children, with the boats' crews and provisions, were ordered into the lifeboats fitted with your gear, and lowered by it without the slightest accident, although there was a heavy sea running at the time. I would not have attempted lowering a boat with such a freight in it by the ordinary method, as it would have been attended with too great risk, and an accident to those poor helpless creatures at such a moment would have been followed by great confusion on board, whereas confidence was inspired in all by the ease and safety with which it was done. I am only very thankful I had it on that trying occasion," &c.

ROYAL NAVAL ENGINEERS.

Before the introduction of steam into ships of war, a ship's company comprised but two classes—gentlemen, and men before the mast. But with the steam engine a new class of persons went on board, and had to find a place for themselves—mainly by some law of moral gravitation, we presume. As a general rule, these new men were of a very different stamp to the gun-room and ward-room officers of a man-of-war. While the former came forth from apprenticeships in workshops and factories, the latter were, for the most part, gentlemen by birth and station. The utter want of affinity between the two classes will, therefore, be readily understood. Nor has the progress of time improved the relations between them to any very great extent. Indeed, as if to aggravate the evil, the Admiralty have unwisely admitted many men of a very inferior stamp into the service as engineers. Yet there must beyond doubt speedily be a closer approximation than heretofore between these classes, or something worse. It is not possible to keep the engineers in their present positions, although those positions are much better than they once were. However unpleasant it may be to born gentlemen to be told it, there is undoubtedly a far larger *demand* for engineers than for them; and when men know they are required, they will and must have their claims attended to. The white-

Digitized by Google

handed midshipman may be doubtful of his destiny, but the greasy-handed engineer must rise. That may sound very sad to some, but it is perfectly true. On shore the same thing may be observed daily. The young gentleman, with his Greek and Latin mysteries, his elegant accent, his charming manners, too often finds a blank future before him, and not unfrequently has to seek his only chance in Australia or San Francisco. On the other hand, no decent man with a fair knowledge of steam engines in his head, or even with a tolerable capacity of managing a steam boiler, is ever at a loss for employment or recompense. Everywhere the blast of the steam engine is blowing fine gentlemen into limbo, and by the vacuum which it leaves behind it, is drawing other men upwards, even from the lowest spheres.

Now, what are the naval engineers just now asking for? We turn to the memorial published in our last number, and we find their demands are exceedingly moderate and perfectly just. They ask first to be allowed, in their several classes, to retire after a certain number of years, like masters, paymasters, and surgeons, with a step in rank. They ask next that all steam-ships which carry a master, a paymaster, and a surgeon, may likewise carry a chief engineer, and not, as now, an assistant engineer in charge. The present system, although it may be thought to give a momentary advantage to the assistant, keeps down the number of chiefs on active service, and is a drag upon the promotion of engineers throughout the navy. They ask next that they may share the privilege which masters and surgeons enjoy, of having a portion of their time before promotion count for service in their new rank. Three years of the "passed" second master's time, and the whole of the assistant-surgeon's time, counts for increase both of full-pay and half-pay. Why should not the same advantage be given to the engineer? Lastly, the memorialists ask that the widows of first assistant-engineers —whose term of service in that capacity averages no less than thirteen years—should be entitled to pensions after a certain number of years' service like those of assistant-surgeons. In support of this request they very properly advert to the *fact* that "the various changes of temperature to which engineers are subjected, as also the great physical exertions required in the performance of their duties, cause a much greater wear and tear of constitution, and therefore more deaths in proportion than with any other class of officers."

Such are the requisitions of the memorialists. It will be seen that all they ask for is a real and *bonâ fide* assimilation of their case to that of masters and surgeons—an assimilation the propriety of which the Admiralty have themselves recognised. It will be our business to show hereafter that there are other changes, not enumerated in the memorial, which the naval engineers have a just right to look for. We have not time or space for setting these forth this week, although we have gathered a mass of facts together for the purpose from the "Navy List" and "Navy Estimates." We shall not, however, fail to pursue the subject without delay.

Meanwhile, as we number many thoughtful captains and other high officers among our readers, we would have them understand that in urging the claims of engineers we only desire for them what is right and proper. We would have those gentlemen remember not only the defects but the merits of the class. Lamenting as we do the grave deficiencies, in point of both education and morals, of many of the men whom the Admiralty have most unwisely entered in that class, we are, nevertheless, anxious that the class itself should not thereby suffer. And, certainly, the business of the engineer is by no means in itself an inferior one. It does, it is true, involve, in its lower grades at least, much of that actual work of the hands which so many affect to despise. But it is not in England, and in this day, that this can be sustained as a ground of objection to a man, or to a class; for however new the process may be to us, it is unquestionably from our *working* men that our future aristocracy has already begun to spring.

ECONOMY OF THE DOCKYARD FACTORIES.

IN looking up facts relating to naval engineers, we have been struck with the extraordinary discrepancy that exists between the costs of the supervision of our factories at the various dockyards. In order to make the matter clear, we have brought the facts of the case together in a tabular form, which speaks for itself. The most glaring discrepancies are observable in the three cases of Woolwich, Sheerness, and Chatham. At Woolwich, the supervision of 520 men costs in salaries £1,825 per annum, while at Sheerness, 556 men (36 more than at Woolwich), have to be managed on very much less than half that sum, viz., £870. In other words, there is at Woolwich a chief engineer officer, who receives £650 per annum, and has £1,175 spent on assistance besides; while at Sheerness, the corresponding officer has to perform heavier duties upon £500 per annum, with £370—less than a third of £1,175—for assistance. We do not for a moment suppose that there are too many officers at Woolwich, or that any of them are too well paid; both suppositions are very far from our thoughts. But we are certainly at a loss to conceive why the engineer at Sheerness yard—who has, in fact, the responsibility of creating as well as managing the factory there —should be placed at the amazing disadvantage which these figures imply. Comparing Chatham and Sheerness, that disadvantage appears even worse. The chief engineer at Chatham actually receives £50 per annum more for superintending 177 men with no factory at all, than the engineer at Sheerness receives for superintending 556 men with a large factory. These are the kind of facts which, among others, are too palpable, we presume, to strike the senses of such reformers as Lord CLARENCE PAGET. While speaking of this subject, we may as well ask why it is that "Chief Engineer and Inspector of Machinery" is written against the names of all the heads of the dockyard factories save one —that of Sheerness—which bears the scanty appellation of plain "Engineer" only?

Abstract Statement taken from the Navy Estimates for the ensuing financial year, 1859-60; showing the cost of Professional Management of the several Steam-engine Factories (including the Metal and Wood Mills at Chatham Yard) in proportion to the number of men employed therein.

SIR JOHN PAKINGTON ON NAVAL SCIENCE.

AT the recent anniversary meeting of the United Service Institution, Sir John Pakington, the First Lord of the Admiralty, who occupied the chair, spoke as follows:—"Never was there a moment when the cultivation of science in connection with the navy was more important to the greatest interests of this country, considering, as one illustration of this position, the extraordinary increase which has taken place in our men-of-war. Perhaps you will allow me to mention, as a remarkable instance of this fact, a statement which it was my duty to address to the House of Commons in speaking of the navy a few evenings since. Only ten years ago, I think, as nearly possible, speaking in round numbers, the construction of a 50-gun frigate cost £50,0000; in the year 1855 the construction of a 50-gun frigate cost rather more than £70,000; and in the year 1858 the construction of a 50-gun frigate cost upwards of £90,000. Now, these are striking and remarkable facts, and they serve to explain many points of which the public is naturally desirous of explanation, but when you find, with respect to the same class of ship, that is to say, a ship that passes by the same name, a ship that is still called a 50 gun frigate, the cost of the construction rising in this ratio in the short period of 10 years, it becomes evident that a great and rapid change is taking place, and that the application of science—and science of the highest order—becomes more and more important with respect to that class of vessels. What is true with respect to a frigate, is of course true as to other descriptions of vessels. I only mention this as an illustration. Then we have to bear in mind the universal application of steam of late years in a new mode and at a gigantic cost. Huge sums of public money have to be expended in those directions; therefore, of course, the cultivation of science becomes all important. At this moment we are about to embark in another wholly new description of construction. I allude to those floating 'cuirassiers.' We are going to have vessels coated with iron. The vessels can only be constructed, or, at least, they can only be made beneficial to the public service when they are constructed, by the most careful application of the most scientific principles. I throw these observations out, gentlemen, merely to show I am sure every man in England who has at heart the welfare of the services, must value an institution which has for its object the promotion of science

Digitized by Google

in connection with them. As I speak, it occurs to me that there is another important element of improvement common alike to the army and the navy, namely, the great and rapid improvements which are now taking place in our ordnance and artillery. And let me here advert, in terms of well-merited eulogium, not only to the great science, not only to the great skill, but I must, in truth and justice, add to the noble and patriotic spirit of Sir William Armstrong. Here again, gentlemen, we have the most abundant proof which must convince every man, be he soldier, be he sailor, or be he civilian, that our welfare as a nation, and the success of our great and powerful arms most essentially depend upon the successful cultivation of science, and therefore any institution which tends to encourage and promote science must be a national benefit."

THE CONSERVATION OF FORCE.

WE proposed offering an observation or two this week upon the paper by Professor Faraday, which appeared in our last number. We find, however, that an exceedingly able contemporary, the *Athenæum*, has so clearly expressed our views on the subject, that we may very well save ourselves the time and trouble of writing down our thoughts on this question. The *Athenæum* says:—

"We need not pay much attention to the additional remarks which Mr. Faraday has made on his *conservation of force* principle. Whether he still continues to attribute his principle to mechanical philosophers in general, he will not allow us to know. We cannot make out the smallest acknowledgement of even any comprehension of the balance which exists in the ordinary principle; on the contrary, we have no doubt that Mr. Faraday has either not read any warning on this subject, or has not understood it. Far from clearing up his views, the additional remarks render them more obscure. He says that he fears he has not stated his views with sufficient precision. And he proceeds thus:—

"'The word force is understood by many to mean simply "the tendency of a body to pass from one place to another", which is equivalent, I suppose, to the phrase "mechanical force". Those who so restrain its meaning must have found my argument very obscure. What I mean by the word "force", is the cause of a physical action; the source or sources of all possible changes among the material particles of the universe.'

"Who, in the name of wonder, is it that calls the tendency of a body to change place by the name of force? It has long been known that a body, say at rest, has no tendency to pass from one place to another, except what it derives from the action of an external cause. The more or less of tendency to change place is the measure of the more or less of force applied: but it is not the force itself. All this is known to every attentive college student, and is only unknown to those who have no notions of mechanics at all. Are we to understand by the paragraph quoted, that Mr. Faraday supposes he has been read by some who were thinking only of the ordinary forces of statics and dynamics, without taking into account those molecular forces, as they are called, which are assumed to exist in treating of heat, chemistry, &c.? If so, he has stated his meaning in very difficult terms. And on this supposition, we have only to say that it would be wise to study the ordinary laws of accessible force, and thence to import knowledge into the much less known subject of molecular actions. If a person talking of force generally feel that he must be obscure to those who take him as speaking only of the forces which are comparatively well understood, how can he hope to be less obscure to those who take him to be also speaking of what is less understood?"

HARBOURS OF REFUGE.

WE have but little to do in noticing the report of Her Majesty's Commissioners on Harbours of Refuge beyond presenting an abstract of the statements which it contains, for all considerations respecting the practical construction of breakwaters, which chiefly interest mechanical men, are left for discussion in a supplementary report to be produced some weeks hence.

The Commissioners state that they have visited the districts of the coast forming the subject of the inquiry, and have there held public meetings at which all the parties interested were afforded the opportunity of being fully heard. They have further obtained in London such additional evidence as it was inconvenient to receive at the outports. After noticing that the annual loss of property from casualties on our coast has been estimated at £1,500,000 sterling, with an average loss of life amounting to 780 persons annually; and before entering in detail upon the grounds on which they have selected the sites for harbours, they advert briefly to the principles that have guided them in arriving at their decisions. The harbours to which their attention has been principally drawn are those "which are required upon such parts of the coast as, being much frequented, are without any adequate place of safety into which vessels can run if overtaken by storms." That such harbours are of great service is sufficiently attested by the use made of them at Holyhead, Kingstown, and Portland, in which 200, 150, and 110 vessels respectively have taken refuge at one time during the last few weeks. But harbours of this discription differ very widely in character from those rendered necessary for the purpose of saving life by the entire want of other than tidal and bar harbours on extensive lines of coast exposed to heavy on-shore gales, and largely frequented by the class of shipping least capable of keeping off a lee-shore; and as these have especial claims on attention, the Commissioners distinguish them by the name of LIFE HARBOURS, leaving to those first mentioned that of REFUGE HARBOURS. On any line of coast the greater number of such ports the better; and therefore the best system to adopt is the improvement of the existing ports, if they are in sufficient number, and if such a course is practicable; but if otherwise, then that the sites for Life Harbours (of which facility of access and sufficient shelter are the only essential requisites) must be sought at that spot on the coast which is most generally accessible from every part of it, evidently if it be straight at its central point, and if a bay, at its head.

The tenor of the evidence received by the Commissioners, especially as respects colliers, points very strongly to the important conclusion, that a considerable number of vessels are sent to sea in a state more or less unseaworthy. They are therefore of opinion, that if on the one hand the public money is to be expended in the construction of Life Harbours, and when every allowance has been made for casualties capable of prevention, loss of life and property, amply sufficient remains to enlist both our judgment and our feelings in that course, on the other hand it is necessary to consider whether any further measures can be taken, either of a public or private character, to ensure that the vessels are seaworthy in their hulls, well-found aloft, sufficiently manned, not overloaded; and that in no case want of seamanship, of sobriety, of vigilance, and losses apparently fraudulent, escape without adequate investigation. Of 1,700 voyages made in fifteen years by vessels in the employ of a Glasgow firm, largely engaged in the colonial and foreign trade, only thirteen resulted in shipwreck, and of these wrecks not one occurred on the coasts of the United Kingdom. This fact strongly corroborates the conclusion, that by far the larger proportion of losses occur among the comparatively inferior vessels frequenting the coasts, and that few happen amongst the generally superior class of vessels proceeding abroad, consequently that it is for the former Life Harbours are chiefly required. Intimately connected with losses at sea, and well worthy therefore of every additional measure which can be taken for its improvement, is the character of the seamen; placed in a not very favourable point of view, by the statement that the same firm has lost during the last six years not less than £20,000 by desertion. But, say the Commissioners, desertion, and most of the other evils justly complained of, "can be traced to causes for which the seamen are by no means solely responsible."

When there is an entire or virtual absence of local interests at the place which the Commissioners select for the site of a harbour, and therefore when the benefit of it is confined exclusively to the passing trade, they consider that benefit to be solely national, and that the expense of its construction should be defrayed from the public funds; and they recommend that the cost of maintenance should be met by a moderate due on the vessels engaged in any trade which may be conducted in it; and in default of this, by an annual vote for the purpose. Where there are local interests of considerable amount at the place selected, they consider that benefit to be partly national and partly local, and in all such cases recommend that the expense of its construction shall be defrayed partly by a grant, and partly by funds raised in the locality. The expense of maintenance in this case is to be a first charge on the harbour dues.

Where there is a small amount of benefit conferred on the passing trade, and the local interests are very large at a port preferring claims for assistance, they consider the benefit to be purely local. They are of opinion that the various harbours recommended should be constructed in whole or in part at the public expense, and as they are national undertakings, a passing toll should not be levied for their erection or maintenance.

The following tabular statement contains a list of all the harbours proposed by the Commissioners, and also the cost of their construction:—

Site.	Grant.	Sum to be raised in the locality.	
		Total.	Of which provided.
	£	£	£
Wick	125,000	125,000	25,000 by British Fishery Society.
Peterhead	100,000	200,000	
Carlingford	50,000		
Waterford	50,000		
Douglas, Isle of Man	50,000	50,000	32,000 by Island Harbr. Comsion.
St. Ives	400,000		
Padstow	40,000		
Tyne River	250,000	750,000	300,000 by Tyne Improvemt. Commission.
Hartlepool	500,000	500,000	
Filey	800,000		
	2,365,000	1,625,000	357,000
Sums proposed by Select Committee of the House of Commons	2,000,000		
Excess	£365,000		

From the foregoing statement it appears that the amount of grants which they propose is greater than that originally contemplated; but they are of opinion that the excess in question is amply justified, since through its means they are to obtain additional harbour improvement to the value of upwards of £1,268,000 raised locally, and that the security for life on the coast, will not merely be extended in a corresponding degree, but is shown to be very inadequately provided for in any other way. It would not be advisable to restrict the annual vote for the construction of these harbours to less than £250,000 per annum, if any regard is to be had to the rate of progress as effecting economy of construction, and they are of opinion that the whole of the works they have recommended should be completed within ten years from the present time.

It is placed beyond doubt, the Commissioners further say, that much benefit may be effected by granting, on good security, loans for works, such as piers and harbours of ascertained public utility, where the work to be performed is beyond the means of individuals and of local associations, and they are of opinion, that there are numerous eligible sites for harbours, where an outlay of inconsiderable amount, compared with the advantages to be secured, would render them safe havens for commercial shipping. In many of these there is no prospect of sufficient pecuniary profit to induce an outlay by individuals or companies. They, therefore, recommend that, in addition to the grants proposed by them, a system of furnishing *loans* in aid of local efforts for harbour improvements should be introduced; and they suggest that some machinery analogous to that set in motion by the *General Inclosure and other Acts*, should be established to enable the parties interested in the projected improvements to submit their plans to the consideration of a Board in London, the special function of which Board should be that of facilitating the construction of such harbours.

In conclusion, the Commissioners say it would be idle to deny that the questions under their consideration have touched very closely the commercial interests and rivalries of neighbouring ports, and the pecuniary interests of large and wealthy districts of country in their neighbourhood, and that corresponding feelings

Digitized by Google

have been very keenly excited. But they indulge in the hope that all those to whose cordial assistance they have been so much indebted during the prosecution of their inquiry will be influenced both by patriotism and humanity to lay aside such feelings, and to join heartily in promoting those measures which may result from their labours, without which they can meet with but partial success. They commend the good work to Her Majesty's protection, in the firm conviction that, if fairly carried out in the spirit of their recommendations, it will prove not the least noble of the many works of benevolence which will illustrate the history of Her Majesty's reign.

LAYING-OFF;
OR,
THE GEOMETRY OF SHIP-BUILDING.
No. IV.

IT will be readily seen that however fair a sheer drawing on the ordinary scale may be, the expanded drawing on the mould loft floor will require to be faired again, and the various sections on the three planes re-adjusted; for any error occurring in the measurement of the drawing will appear on the floor multiplied by 48. In effecting this re-adjustment, an artifice is adopted which greatly reduces the labour. This consists in shortening all the horizontal projections by drawing the projections of the transverse sections closer together, and making them, say, 3 inches apart, instead of 30 inches—the ordinary *room and space*. All the breadths, or the distances of the intersections of the several projections from the axis remain unaltered, so that they may be measured in the body, and set off in the half-breadth, or *vice versâ*, just as before. Two important advantages arise from this arrangement—the first is, that the quantity of ground to be travelled over in drawing the lines is greatly reduced, and the second, that when the points in the several curves to be drawn are brought so close together, any unfairness can be immediately detected. If, for example, in Fig. 13, page 139, the distance of the point *c* from the axis were too small, it might be difficult to perceive the error were the intervals between the points *a b c d e* great; but if they are brought near each other, it would be impossible to force the batten through the false point. That this mode of operation is admissible may be seen if we reflect that it only amounts to obtaining projections upon a new horizontal plane inclined at a very considerable angle to the plane of the water's surface, so that although the distances between the points—measuring parallel to the axis—are reduced, they all occupy their proper relative positions.

The most suitable lines which can be chosen for this contracted half-breadth plan are diagonals. Level lines are sometimes taken, but they will not detect an error so readily as the diagonals, because they are not so nearly at right angles to the transverse sections which they are required to correct. When the breadths taken from the body are found to produce fair *level* diagonals in the half-breadth, the transverse sections may be assumed to represent the correct form of the ship at the positions which they respectively occupy. We must consider here a point of great importance in completing this operation of fairing, viz., the mode of determining where the lines should end at the rabbets of stem, keel, and sternpost.

We have represented in Fig. 15 a portion of the stem and keel, showing the rabbet or groove in which the ends of the plank are buried; *a* is the front of the stem, *b* the under-side of the keel; *c* is a portion of the fore edge of rabbet of stem, and *d* of the lower edge of rabbet of keel, *i.e.*, *c d* is the line in which the outer surface of the planking and the sides of the stem and keel meet. At this joint there is a seam which requires to be firmly caulked; this makes it necessary to work the planks a little longer on the inside than on the outside to prevent the ends from being forced off from the bottom when the oakum is driven in. This need not be considered in ending the lines; it is sufficient to suppose all the ends of the planks to be cut off square, in which case, the inner edge of the butts will be a continuous curve represented by the dotted line *e' g'*, and known as the middle of the rabbet. This line continued through the stem, keel, and stern-post, will form the boundary of the inner surface of the planking, or the outer surface of the timbers, which is the surface requiring to be dealt with on the floor. As all the sections of the ship will end at this line, it will be better to consider how it may be

FIG. 15.

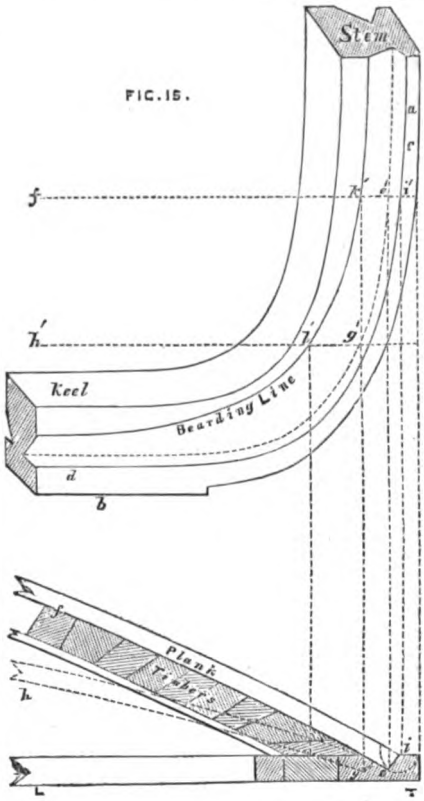

FIG. 16.

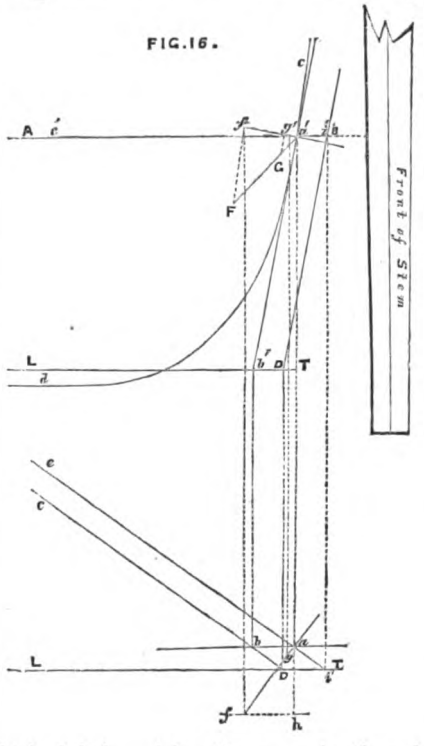

obtained before giving the approximations by means of which it may be dispensed with. The only line given to guide us is *c d* (Figs. 15 and 16) continued throughout the ship. This line, it will be seen, is quite arbitrary, while that which we seek is dependent upon it, and upon the form of the ship. For example, where the bow is very sharp the middle and the fore edge of the rabbet will fall very near together, and will separate again as the bow becomes more bluff. To determine this line, it will be necessary to find several points in it in the following way.

Draw a short level line *A B* at the place where it is desired to find a point in the required line, and let the line *A B* meet the fore edge of rabbet in the point *a'*. It must be observed that the stem tapers from the under-side of the 'lower cheek' to the 'fore-foot', as shown (Fig. 16), so that the horizontal projection of the point in the fore edge of the rabbet corresponding to *a'* will be *a*, lying in the line *a a'* drawn perpendicular to *L T*, and at a distance from the axis equal to the half breadth of the stem at the height of the level line. Now, what we desire to do is to set in from the point (*a*, *a'*) the thickness of the plank, say four inches, in a direction at *right angles* to the surface of the planking at (*a*, *a'*) because 4-inch planking measures more than four inches in any direction not square to its surface.

We see that a small portion of the surface of the bottom at (*a*, *a'*) is a plane containing a short piece of the line *c d*, and also of the level line *A B*. If we can discover this plane, it will be easy to draw a line through (*a*, *a'*) perpendicular to it, and upon such line to set off the 4 inches. Draw then, the line *a' b'* coinciding with *c d* at *a'* and extending down to *L T*, which is drawn at a distance equal to the thickness of the plank of bottom above the lower edge of the rabbet of keel, and is called technically the *upper* edge of the rabbet of the keel. It forms a convenient base line or axis, but it represents nothing in the ship. The line *a' b'*, thus drawn, will be the vertical projection, and *a b* drawn with the taper of the stem the horizontal projection of the tangent to *c d* at *a'*. We must now find the projections of the tangent to the *level* line at *a'*. For this purpose a penning batten must be passed through the points obtained on the sections for the level line, and brought down to touch the back of a circle swept from *a*, with a radius equal to the thickness of the plank. This will give us a very close approximation to the direction of the surface, and a line *a e* drawn parallel to the foremost portion of the approximate level line may be assumed to be the horizontal projection of a tangent to the outside of the planking in the section *A B*, and at the point (*a*, *a'*); the vertical projection of this tangent is *a' e'*. The horizontal trace of the plane which contains these lines, must contain the horizontal traces of the lines. Now, (*a e*, *a' e'*) has no horizontal trace, and that of (*a b*, *a' b'*) is *b*. Moreover, the horizontal trace of a plane containing a line parallel to the plane of projection must be parallel to the horizontal projection of the line, from which we conclude that *C D* drawn through *b*, parallel to *a e*, is the horizontal trace of a plane containing the lines (*a b*, *a' b'*) and (*a e*, *a' e'*). Again (*i*, *i'*) the vertical trace of (*a e*, *a' e'*), must lie in the vertical trace of the plane we seek; this trace is, therefore, *D i'* or *D B* and the tangent plane to the surface at (*a*, *a'*) is *B D C*. From *a'* draw *a' f'* perpendicular to *B D*, and from *a* draw *a f* perpendicular to *D C*; then (*a f*, *a' f'*) is a line drawn from (*a*, *a'*) perpendicular to the plane *B D C*. It may be of any length. Having determined its length by marking the point (*f*, *f'*), we must proceed to *rabat* it in order to discover the true distance between (*a'*) and (*f f'*). This true distance is the hypothenuse of a right-angled triangle of which the base is *a' f'*, and the perpendicular the distance which one end of the line is *within* the other, *i.e.*, *d*, so that if we draw *f' F* perpendicular to *a' f'* and equal to *a h*, and join *a'* and *F*, *a' F* will be the true length required. It is on this line *a' F*, which is a *normal* to the surface at *a'*, that the thickness of the plank is to be set off. Set off then *a' G* equal to the thickness of the plank, and draw *G g'* perpendicular to *a' f'*. It will be seen that if *a' F* were swung back about *a' f'* until it reached its proper position—perpendicular to the surface of the planking—*a' G* would be a line across the

Digitized by Google

square butt of the plank, and also perpendicular to the surface. We know, moreover, that it represents the proper thickness of the plank, and we therefore conclude that it is a point in the middle of the rabbet. If G is such a point, g' must be its vertical projection, for $G\,g'$ is drawn perpendicular to $a'\,f'$, and, therefore, perpendicular to the plane of projection. Or, looking at it in another way, the length of the vertical projection of any portion of the normal must always be to the length of the portion projected as $g\,f'$ is to $a'\,F$, and $f'\,g'$ bears that proportion to $g'\,G$. Any number of points like g' having been discovered by a similar construction the curve joining them would be the middle of the rabbet in the sheer; the corresponding point g in $a\,f$ would be in the middle of the rabbet in the half-breadth, and a point in the body at the same height as g', and at the same distance from the axis as g would be in the middle of the rabbet in body; so that by means of a series of such points curves could be obtained in all the plans. Having discovered these curves, if it be required to end the level line $e'\,f'$ (Fig. 15), we have only to draw from e' where it meets the middle of the rabbet, $e'\,e$, meeting the middle of the rabbet in the half-breadth in e, and this point e will be the end of the horizontal projection of the level line. Or again, to end a diagonal line, set up from the base line in the sheer the height at which the diagonal crosses the middle of the rabbet in the body, and thus discover the ending in the sheer; let fall from this a perpendicular to the middle of the rabbet in the half-breadth, and we have the ending of the horizontal projection of the diagonal. If the diagonal is rabatted or expanded, the expanded line will end at a point squared out from the one just found, and at a distance from the axis equal to the length of the portion of the diagonal intercepted between the axis and the middle of the rabbet in the body. If a transverse section is to be ended in the body find the height at which it crosses the middle of rabbet in the sheer, and a point at the same height in the middle of the rabbet in the body will be the ending. We may observe before passing from this problem that if the stem be supposed to have no taper, $B\,D$ would be parallel to $a'\,b'$, for the same reason that $C\,D$ is parallel to $a\,e$, and there would be no necessity for getting in the tangent plane, as we could find the directions of $a\,f$ and $a'\,f'$ by means of the lines $a\,e$ and $a'\,b'$, and could then construct the triangle $a'\,f'\,F$, and proceed as before. This mode of solving the problem is similar to that adopted by Marmaduke Stalkartt, who makes the assumption that the stem is of parallel siding from the head to the heel; but, as the value of the problem is in any case mainly theoretical, we have striven to give it the greatest possible exactness. Draftsmen sometimes adopt the construction of Stalkartt, and end the lines in the way described, but the ordinary mode of ending level lines, water lines, and sheer lines, is to sweep a circle from i, fig. 15, or from a, fig. 16, with a radius equal to the thickness of the plank, and to let the line touch the back of this circle. Although this is incorrect, it has the advantage of leaving an excess of wood in the rabbet. If the fore edge of rabbet were vertical and the stem did not taper there would be no error, for the surface of the planking would be perpendicular to the horizontal plane; and any inclination in this surface arising either from the obliquity of the fore edge of rabbet or the taper of the stem, increases the thickness of the horizontal section of the planking, and makes it necessary that $e\,i$, Fig. 15, should be greater than the given thickness. In Fig. 15 there is a line marked *bearding line*. This is really the after edge of the rabbet of the stem, the upper edge of the rabbet of the keel, and the fore edge of the rabbet of the stern-post. It is obtained on the stem, as shown in this figure, by finding points k' and l' in the level lines in the sheer, vertically over those in which the same lines in the half-breadth are cut by straight lines representing the half-siding of the stem at the height of the respective lines. The bearding line on the stern-post and after deadwood are obtained in the same manner. To find the bearding line along the keel, measure the heights at which each transverse section in the body is cut by the half-siding of the stem, keel, or stern-post at its station, and set up such heights on the respective stations in the sheer. All the diagonals are ended at this line, as the harping, the forms of which they are intended to determine, do not go beyond it, but turn off at it and follow the side of stem or stern-post. The ending of one of these diagonal lines is obtained by measuring in the body the height at which it cuts the side of the stern or stern-post, setting it up on the bearding line in the sheer, and then dropping a perpendicular and finding the corresponding point in the side of the stem or stern-post in the half-breadth.

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, MARCH 10.

HOUSE OF COMMONS.

PIERS AND HARBOURS.

Mr. PINLAY asked whether it was the intention of Her Majesty's Ministers to introduce a Bill to facilitate the construction of piers and harbours; and, if so, when?

Sir J. PAKINGTON stated the introduction of the Bill was postponed till the report of the Harbour Commission should have been considered.

FRIDAY, MARCH 11.

HOUSE OF COMMONS.

RIFLED CANNON.

The order of the day for going into committee of supply having been read,

General PEEL, in reply to General Evans, said he did not think it would be quite prudent to state how many of Armstrong's guns were expected to be constructed during the present year. He had upon a previous occasion informed the House that the Government would have those guns made as quickly as possible, and that it was their intention to establish a manufactory for them at Woolwich.

DOCKYARD EXPENDITURE.

A lengthened discussion then ensued on Dookyard Expenditure, Lord Clarence Paget commencing it, and being followed by Sir John Pakington, Sir Charles Napier, Mr. Bernal Osborne, Mr. Bentinck, Sir F. Baring, Sir G. Pechell, Sir. J. Elphinstone, Mr. M. Gibson, Lord J. Hay, Mr. W. S. Lindsay, Sir C. Wood, Mr. Corry, Lord J. Russell, the Chancellor of the Exchequer, and Mr. Joseph Locke. The statements brought forward in the discussion appear in another column. The motion of Lord C. Paget was to the effect, "That, in conformity with the practise of the public departments of laying before the House detailed estimates for works costing above £1,000, it is desirable that a statement in the following form, showing the proposed expenditure in the construction and conversion of her Majesty's ships, be annually laid before this House with the navy estimates—viz., name of ship, tonnage, horse power, total estimated cost, amount already voted, gross sum already expended, amount proposed, 1859-60, further amount required to complete, remarks."

When the House divided the numbers were—

For the motion of Lord C. Paget	97
Against	117
Majority against the motion.	——20

MONDAY, MARCH 14.

HOUSE OF LORDS.

ELECTRIC TELEGRAPH GUARANTEES.

Lord STANLEY of ALDERLEY, in moving for copies of all contracts entered into by Her Majesty's Government with any Electric Telegraph Companies, expressed a hope that in all these contracts care might be taken to include a power to the Secretary of State, by warrant, to take possession of the telegraph, on any sudden emergency, for so long as he might think the public interest required, compensation being made to the company.

The Earl of DONOUGHMORE said there would be no objection to the return.

Lord REDESDALE objected altogether to the principle of guarantees. They were entirely unnecessary, and had the effect of deterring the construction of useful works, for when once the practice was established no work would be undertaken without a guarantee.

The return was then agreed to.

HOUSE OF COMMONS.

DOCKYARD EXPENDITURE.

Sir J. PAKINGTON said, in consequence of the statement made to the House on Friday evening by the noble lord the member for Sandwich (Lord C. Paget) that, in the course of the last 11 years, of the sums voted from time to time by the House of Commons for the expenditure of our dockyards, no less than 5,000,000*l.* have not been accounted for, or have been absorbed by what the noble lord called reckless extravagance, I wish to give notice that in the course of a day or two it is my intention to lay on the table, together with the reports of the committees I have already promised, a full statement of how the money voted by the House during these 11 years has been appropriated. And it is my intention that this statement shall be given as much in detail as it is in the power of the department of the Surveyor of the Navy to supply.

METROPOLITAN DRAINAGE.

Mr. WILLIAMS asked what steps had been taken by the Metropolitan Board with reference to the main drainage of the metropolis, particularly on the south side of the river.

Mr. TITE had obtained from the chairman a correct account of the present state of the works. On the south side of the river there were two systems of sewers—the high level and the low level. The high level sewer began at Clapham and ended at Deptford; it was 10 miles in length, and its estimated cost was £203,000. The contracts for this sewer had been concluded last week. The lower level sewer began at Putney and ended at the same point as the higher one—Deptford; it was 11 miles long, and the contracts for it would be advertised in June next. The two systems of drainage on the south side of the river would end at the same point at Deptford Creek, where the contents of the lower sewer would be pumped into the higher one and flow into the estuary of the Thames at Erith. On the north or city side of the river there were three systems of sewers; one began at Hampstead, and ran for seven miles and a quarter to a terminating point on the river Lea. The cost of this sewer was estimated at £252,000, and it would probably be finished in 12 months. The second sewer began at Kilburn, and ended at the same point on the river Lea as the first—a distance of 10 miles; it would be contracted for at the end of the year. The third system, being involved with the embankment of the Thames, would require a longer time in construction. All these systems meeting at one point on the Lea, the water would there be raised from the lower to the higher level, and run in a common conduit to the sea at Barking Creek. The works would be completed in four years; the whole of the money, £3,000,000, had been advanced by the Bank of England, at 3½ per cent. It was estimated it would all be paid off in 40 years by a 3d. rate on the metropolis.

THE NAVAL ESTIMATES.

On the question that the House may go into Committee of Supply upon the Naval Estimates,

Mr. WILLIAMS moved that they should be referred to a select committee. After remarks from Sir H. Verney, Sir H. Willoughby, Mr. Lindsay, Col. Sykes, Admiral Walcot, Sir F. Baring, Mr. Bentinck, Lord H. Vane, Lord C. Paget, Sir J. Pakington, Mr. B. Osborne, Sir C. Napier, Mr. Jackson, and Sir C. Wood, Mr. Williams' amendment was negatived without division.

DECIMAL COINS FOR CANADA.

THE coinage of decimal pieces for Canada still goes on at the Mint simultaneously with the ordinary coinage for home use. More than three millions of twenty, ten, and five cents, equal in weight and value to the franc, half, and quarter-franc of our belligerent friends "over the water," have already been despatched to that colony, and now one-cent coins of bronze are being produced. This latter may be considered, indeed, a model coinage. It is at once economical, artistic, and convenient. The bronze used is a mixture of copper, tin, and zinc—in the proportions of 95, 4, and 1—and thus gives a metal harder and more durable than copper alone. The pieces are, in comparison with our own copper currency, thinner and larger in diameter. For instance, farthings are 7-8ths of an inch in diameter, and there are 96 of them to the lb. avoirdupois; but the Canadian one cents are just an inch across and there are 100 of them to the lb. When it is considered, too, that they are current at the same value as the halfpenny, the economy of metal becomes at once apparent. The design of the obverse is chaste and pretty. Her Majesty's portrait, with the legend, VICTORIA, REGINA DEI GRATIA, CANADA, surrounded by an undulating wreath of maple leaves, comprises it. The reverse has a similar wreath, with the words, "One Cent," and the date, "1859," in the centre. Twenty tons' weight, or nearly 4½ millions, of these admirable coins are being, we are told, struck, and certainly the Canadians may be congratulated upon presently obtaining a perfect decimal currency, whilst the English people are but *thinking about* adopting the valuable improvement. Why should the population of these islands—to put the matter in a point of view as regards convenience only—be always carrying about 6,000 tons of metal in the shape of copper coins, when 3,000 tons or less, of bronze, well adapted for wear and tear, and for displaying the fine lines of the engraver, would answer the same purpose? When, indeed, may we expect a decimal coinage?

Mr. W. Phelps, of Red Lion-square, London, suggests "the employment in wet gas meters of an aqueous solution of deliquescent metallic and earthy salts, kept constantly neutral by the presence of a base or carbonate," instead of the ordinary water.

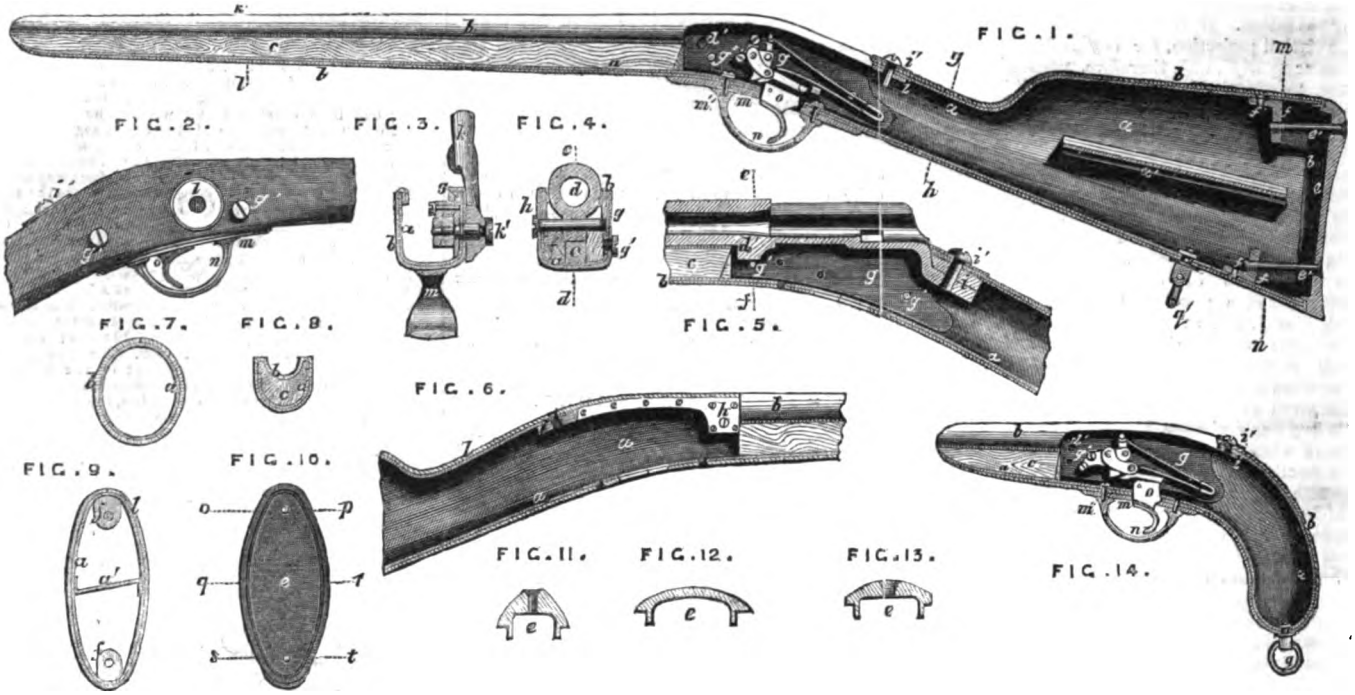
MANCEAUX'S METALLIC STOCKS FOR FIRE-ARMS.



MANCEAUX'S METALLIC STOCKS FOR FIRE-ARMS.

M. François Jules Manceaux, of Paris, one of the first gun-makers of France, has just completed a patent in this country for forming the stocks of muskets, pistols, and other fire-arms of a combination of wrought iron (or other metal), wood, and leather. He prefers to use thin wrought-iron plates as the most suitable metal. This he bends and fashions into the form of stock to suit the arm for which it is intended. All that part in front of the lock which supports the barrel is open and dished or curved to receive a block of wood hollowed out at top for the barrel to lie in. The butt-end of the stock is furnished on the inside with strengthening pieces to prevent the ends collapsing. A sheath of cow-hide or other suitable leather is stretched in a damp state over the metal and wood, and a barrel is forcibly pressed down on the leather over the fore part of the stock to cause it to assume the exact form of the stock. The open ends of the leather sheath are turned in and secured over the butt-end of the metal frame. The leather is then heated and plunged in a bath of melted wax, and after being thoroughly saturated the wax is drained off and the leather polished by brushes. A solid butt-piece of metal is screwed into the open butt-end off the metal frame. The lock is contained in the hollow of the stock, and is held by screws; a transverse screw bolt passing through a hole formed in a block on the bottom of the breech-end of the barrel keeps the barrel in place. A metal plate is screwed in outside the leather to receive the friction from the working of the hammer of the lock.

Fig. 1 is a longitudinal section of the stock of a fire-arm constructed according to this invention, and showing the lock. Fig. 2 is an external elevation of part of the stock, showing a plate on the side of which the hammer is to work. Fig. 3 is a cross section. Fig. 4, cross section through the line *e f* of Fig. 5, which is a longitudinal section through *c d* of Fig. 4; Fig. 6 is also a longitudinal section through *c d* of the opposite side of the arm; Fig. 7 is a cross section through *g h* of Fig. 1; Fig. 8, cross section through *k l* of Fig. 1; Fig. 9, cross section through *m n* of Fig. 1; Fig. 10 is an internal view of the butt-plate; Figs. 11, 12, and 13, are cross sections respectively through the lines *o p*, *q r*, and *s t* of Fig. 10; Fig. 14 is a sectional elevation of a pistol stock, showing the lock. The patentee first forms moulds and dies in metal, and then by successive heats, and under hydraulic or other pressure, fashions a sheet of plate-iron into the form required. He brazes the edges of the plate, and makes a perfect joint. This is the shell or carcass of the improved stock. He next furnishes the interior of the rear-end of the shell with a Z-shaped strengthening piece, *a'*, Figs. 1 and 9, to prevent the sides collapsing, and with two nuts, *f f'*, screwed to the shell to receive the ends of screws for holding the butt plate of the stock. The fore part of the metal shell is filled with a bed of wood, *c*, Figs. 1, 8, and 14, hollowed out at top, and riveted to the shell. He next takes a hide, *b*, of the shape shown, and sews it up at the sides to form a sheath. The leather is softened by steeping, and while wet, or damp, is drawn over the metal shell and wooden bed until the two open ends extend beyond the shell; a false barrel is then placed over the leather, and secured over the wooden bed by screw or other clamps, to cause the leather to assume and follow the shape thereof. A wooden block is introduced between the turned-over edges of the leather at the breech, see Figs. 1, 4, 7, 8, and 9. In drying, the leather follows the exact form of the shell, and in order to dry it thoroughly, he introduces and works about a hot iron inside of the hollow part of the stock. He next plunges the stock in melted wax, and rubs the wax into all the pores of the leather. He then allows the wax to drain off, and the stock to cool; when cold he polishes the waxed leather with a rubber and brush. One end of the sheath is turned in over the butt-end of the shell, and is covered and secured by a rim, *e*, in the inside of the butt plate, which is attached to the nuts *f f'* by the screws *e'*, *e'*. The opposite end of the sheath is turned in over the wooden bed. The lock is placed bodily in the hollow of the shell, and is there fixed by screws, see *g' g'*, Figs. 1 and 5; *k* is the hammer, secured on the spindle by the screw *k'*; *g* is the lock plate held inside the shell by the screws *g'*, *g'*; *l* is a metal collar screwed to the outside of the shell, against the face of which the side of the hammer works, and is thus kept from chafing the leather; *d* is the barrel placed in the bed in the fore part of the stock, and secured by means of a screw, *d'*, which traverses a hole made in a lump on the underside of the barrel, and if a screw, is screwed with a block, *i*, in the rear of the barrel; *h* is a strengthening block inserted into the shell of the stock on the side opposite the lock-plate, for the purpose of giving additional solidity of the stock at that part, and for maintaining the barrel in the centre of the stock; this block is traversed by the screw *d'*. At the further end of the stock there is a ring, *p*, which encircles the barrel, and is secured to the stock by a screw. If thought necessary, in order to protect the extreme end of the barrel, the wooden bed might be prolonged, and fastened by rings to the barrel, as in the ordinary military musket. The wooden bed should be covered over its whole length with leather, and then the leather sheath might be composed of two parts united at the breech, or other suitable part; *m* is the guard-plate screwed to the under part of the shell, and *n* the guard; *o* is the trigger which works in a slot made in the shell; *q q'* are buckles for attaching a sling.

STEAM FIRE-ENGINES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Fire Engine and Pump Manufactory,
245 Blackfriars Road, London, 16 March, 1859.

GENTLEMEN,—Referring to the number of the Magazine dated the 4th instant, we find several strictures by an anonymous correspondent upon our Steam Fire-Engine, but as we have two in hand nearly completed, with which we intend to have various public trials, we decline, at present, entering into a controversy upon the subject; at these trials your correspondent and the public will have ample opportunities of acquiring the fullest information. With regard to that part of his letter in which he states that the attempt to work the engine in St. Petersburg proved a failure, we beg leave to hand you the following letter:—

"Messrs. Shand and Mason. "March 15, 1859.

"GENTLEMEN,—In reply to your inquiries as to the performance of the Steam Fire-Engine sent by you to St. Petersburg last autumn, I beg to say that we were very fortunate in our various trials with the same. In the first, which was private, we worked it with two of the larger (¾) and to of the smaller (½) jets, and kept her at work for about three hours. The most severe trial was the third—the cold being 18° Reaumer, nevertheless she performed very satisfactorily. The Count Struvaloff, our Chef de Police, and the other authorities, were very well satisfied both with the quantity of water thrown and the force with which it issued from the pipe. Since my arrival in this country, I have received intelligence that it was used at the fire which took place at the Theatre Cirque, and although worked by the men of the brigade, did very well during the eight hours which the fire lasted. "Yours truly,

"(Signed) H. B. FROOM."

We are, gentlemen, yours very respectfully,

SHAND AND MASON.

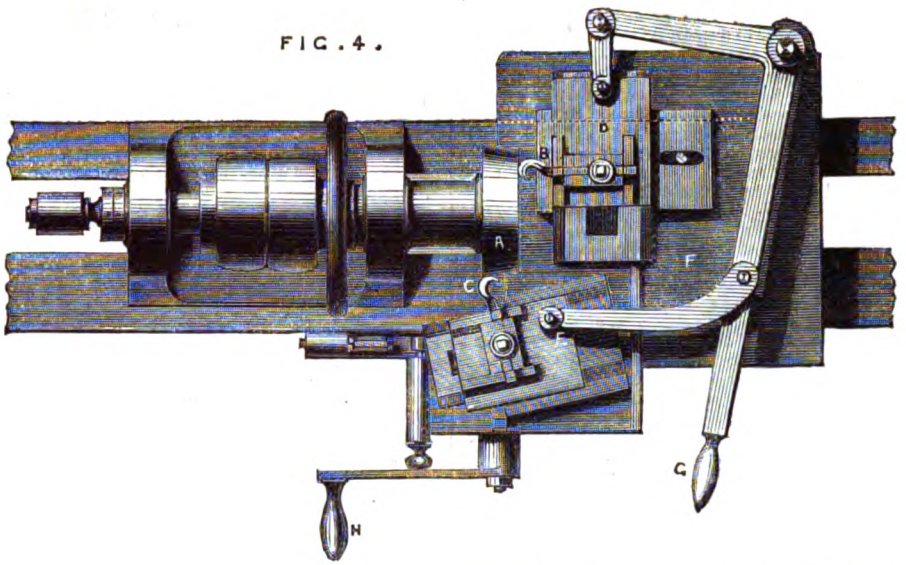
FIG. 4.



MACHINERY FOR TURNING.

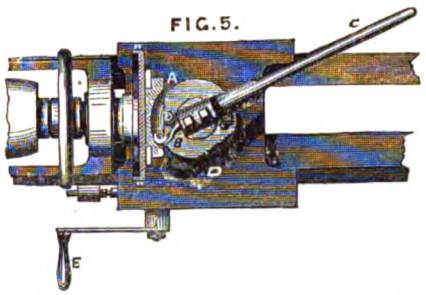
ON SOME APPLICATIONS OF THE COPYING OR TRANSFER PRINCIPLE IN THE PRODUCTION OF WOODEN ARTICLES.

By John Anderson, Esq., F.R.S.,
*Inspector of Machinery, Woolwich Arsenal.**

A distinguishing characteristic of the arts and manufactures of the present century as compared with those of the past consists in the application of the principle of machine copying, in contradistinction to dependence on the skill of the operative, in the production both of the ordinary articles of commerce and of the munitions of war. Engineers are so familiar with this principle in their every-day pursuits, that it frequently escapes their notice; yet a closer inspection will show that almost all machines that are intended to change the form of materials are constructed on some modification of this principle, of having the form in some way or other contained in the apparatus, with the specific object of imparting that form to the materials under operation; and it will generally be found that every process which is done well, and which at the same time is done cheaply, is performed by some skilfully-arranged development of this principle. The advantage of keeping first principles steadily in view in practical applications of science is generally conceded: the knowledge of facts is considered good; but to know the law of the facts is considered better, and much more likely to hasten onwards their more extended application. A complete exposition of the various applications of this copying principle in the several arts and manufactures of the world would form a highly interesting and valuable volume.

Within the last few years a remarkable change has taken place in this respect. With regard to the tools of the smithery, production by the hammer and hand of the smith is fast giving place to production by means of apparatus constructed upon the copying or transfer principle: such as dies under the American drop hammer, the steam hammer, and the forging machine; the employment of rolls containing on their surfaces the pattern of what is wanted; and the use of oscillating dies imparting the form to the red hot mass upon a moving table. In each case it is seen that the general tendency is to obtain the form and dimensions of the article produced by the transfer of both from an apparatus prepared with care; and to dispense with that care in the future actual production. The moulding operations of the foundry are pre-eminently copying; or, if it is attempted to analyse the recent improvements in the moulding of wheels, shells, railway chairs, and such articles, it will be found that all are designed with a view to have the accuracy and perfection of form provided in the apparatus, from which it is then transferred to the sand without so much skill being required on the part of the workman who performs the ramming of the mould. The other workshops of the engineer present that invaluable development of the copying principle termed the slide rest, assuming every variety and modification in the several machines used for turning, boring, drilling, planing, or shaping. The same principle in combination with circular cutters affords the machinery of the Small Arm Factory, the endless variety of which would alone form an interesting subject.

FIG. 5.



The object of the present paper is to give a description of a few applications of the copying principle in the production of certain articles mostly in connection with the simple operations of wood-turning, which have been more immediately brought under the notice of the writer; and although they are trifles in themselves, still it is only by each one making a small contribution from time to time that the improvements in the details of the several workshops can be made generally known to one another.

During a short professional tour in the United States in 1854, the writer was much struck with the many simple and ingenious contrivances there introduced, in order to apply the copying principle in connection with ordinary hand-lathe operations, where generally in this country more would be dependent upon the skill or attention of the turner or upon special machinery. For example, in the production of articles where there is repetition and which are to be turned in a common lathe, the application of certain very simple additions tends greatly to facilitate the operation, and to enable the operator to dispense with the usual measuring and gauging and the use of callipers, which generally occupies so much time.

A simple arrangement of a copying lathe is shown in Fig. 1. At the front of the lathe and parallel with the piece of wood *A* to be operated upon, there is fixed a strait edge, *B*, made of hard wood, with the upper or straight edge slightly hollowed. At the back of the lathe there is a similar fixture, *C*, only the upper edge is not straight but resembles the irregular form of the required article. The gouge or turning instrument, *D*, instead of being held in the hand of the turner over a rest, is fixed into a piece of wood, *E*, the arrangement slightly resembling that of a carpenter's plane, having one end adapted to slide firmly on the straight edge *B*, at the front of the lathe, while the other is adapted to trace the irregular line *C*, running along the back. In order that the workman may gradually reduce the wood to the proper diameter without the risk of digging into the mass and thereby breaking the cutting instrument, a small wedge of wood, *F*, is attached by a loop to the little finger of his right hand, and at the commencement of the operation is inserted between the toolholder *E* and the irregular pattern *C* at the back of the lathe, but is gradually withdrawn as the article approaches the required diameter; and at the last, a finishing tool is slowly and carefully drawn along the two guides *B* and *C*, thus producing the exact pattern without any effort, and in much less than half the time in which it could be done in the common way.

On a similar plan to the foregoing, but differently arranged, is the American system of turning long poles of small diameter, as shown in Fig. 2. The wood, *G*, to be turned is first cut by a circular saw into square rods of the required length; these are then placed between the centres of a turning lathe, with the corners still upon them. The toolholder or cutting apparatus, *H*, slides steadily upon two parallel straight edges, *I I*, placed respectively at the front and back of the lathe: this toolholder consists of a metal socket, *H*, having cutting gouges, *K* and *L*, at each end; the foremost gouge, *K*, is set to reduce the square rod to the internal diameter of the socket, *H*, in order to obtain perfect steadiness; while the second or finishing gouge, *L*, is set to reduce the pole to the required diameter. To relieve the workman from the trouble of pushing the socket, *H*, with its cutting tools along the lathe, the interior of the socket is made with a screwed surface; and the first gouge, *K*, being set to give a tight fit, the thread which is thus formed upon the wood draws the socket along; and as the second gouge, *L*, is close to the hinder end of the socket, the thread does not make its appearance, being cut off by the second gouge, which is set to give the proper finished diameter to the work. In turning long small poles of an irregular figure, the second tool, *L*, is not a fixture upon the socket, but is held in a toolholder having one end hinged upon the socket while the other traces the required pattern placed alongside, thus causing the tool to rise or fall as it slides along the pattern.

It may be mentioned that the American woodturners use a centre which is not common in this country; and having been introduced into the Royal Arsenal with great advantage, its general application can be recommended. This lathe centre, which is shown in Fig. 3, instead of having the ordinary sharp point, is formed at the extremity with a hollow cup, *M*, surrounded by a sharp circular edge; this when pressed into the revolving wood forms a hard centre within itself, by compression of the wood within the conical cup, which is better adapted both to retain the oil and also to continue uninjured during a long period.

The method of turning the sabots or blocks of wood which are attached to round shell, as performed in the arsenal at Woolwich, affords another illustration of the successful application of the copying principle. Hitherto these articles have been produced by the wood-turner with the gouge, chisel, and gauges, in the usual manner; it was a monotonous and very

* Paper read at the Institution of Mechanical Engineers.

Digitized by Google

laborious process, and a skilled workman could produce only about fifty of them per day. By the new method, the wood is first cut out of the plank into circular pieces by means of an ordinary trepanning tool, costing for wages an average of 7*d.* per hundred. The wooden disc is then perforated by a drilling machine, in order to prepare it for being screwed upon the face plate of a turning lathe.

The first turning process is to form the exterior surfaces; and for that purpose the wood is screwed upon the centre screw of the face plate, as shown at *A*, Fig. 4. The tools or gouges, *B* and *C*, that are required to produce the form are contained on separate sliding rests, *D* and *E*, combined together upon one saddle, *F*, both being actuated by the movement of a single handle, *G*. The saddle, *F*, itself is made to slide upon the lathe bed in the ordinary manner, by means of a rack and pinion, and is moved by the left hand of the workman by means of the handle *H*. The dimensions of the sabot are determined by a stop upon the lathe bed against which the saddle, *F*, is pressed, and also by the adjustment of the gouges.

The next and last operation is to hollow the sabot for the reception of the shell. For this purpose a similar lathe is employed, shown in Fig. 5; the block, *A*, is held in a universal chuck adapted to the article. The required hollow being part of a true circle, the gouge, *B*, is fixed upon a holder which is capable of turning on its axis by means of a handle, *C*; the radius of the circle described by the gouge depending on the distance at which its cutting edge is set from its centre of motion. The toolholder is mounted upon the saddle, *D*, of a lathe, as in the former operation, the depth to which the hollow is cut being determined by a stop fixed upon the lathe bed and adjusted with reference to the face plate. In performing the operation the workman moves the saddle, *D*, with his left hand by a rack and pinion by means of the handle *E*, while with the other hand he gently moves the handle, *C*, of the toolholder, making the gouge describe an arc of a circle.

It will thus be seen that no skill is required during any of the producing operations, and that the form and dimensions of the article are in each case contained in the apparatus. To make sabots of other forms, the several slide-rests are readjusted upon the saddle. The saving in wages effected by these arrangements amounts to more than four-fifths of the original cost.

For another but smaller class of articles of similar shape, of which three or four hundred thousand are required daily, a different modification of the principle of copying is employed. The conical plug of the Minie bullet is made of boxwood by self-acting machinery. In this manufacture, the conical form of the plug is contained in a revolving cutter, which is fixed in a lathe spindle and driven at a high velocity. The wood having been first cut up into long square rods by means of circular saws, one of the wooden rods is fixed upon the lathe saddle, and pushed forward against the cutter; this gives a conical form to the end of the rod, which is then cut off by means of a circular saw, forming a plug of the required shape and dimensions.

(To be concluded in our next.)

THE NEW METAL ALUMINIUM.

A VERY interesting paper on aluminium was read at the Society of Arts, on Wednesday, the 2nd ult., by Mr. Foster, the able Secretary of that Society. First mentioning the extension which chemical knowledge has undergone in modern times, and the boundless supply of aluminous substances which has thus been opened up—in granites, slates, schist, and especially in clays—the author pointed out the fact that aluminium forms an essential portion of our most brilliant gems, including corrundum, the sapphire, and the Oriental ruby and emerald; and then proceeded to remark that, notwithstanding the universal diffusion of ores of aluminium, the existence of the metal itself was not known until the last half-century, and its extraction has been attended by great difficulty. He then detailed the means adopted for producing sodium by Davy, Gay-Lussac, Thénard, Mitscherlich, Brunner, Donny, Mareska, and, more recently, Deville; and traced the labours of Oersted, Wöhler, and Deville, in the production of aluminium. After quoting from the paper read by the Rev. J. Burlow, in 1856, on Deville's process, noticing the modifications which Paul Morin introduced, and sketching the labours of Dr. Percy, Mr. Dick, and Rose (of Berlin), the author stated that—

Mr. Gerhard, an Englishman, has for some little time past been engaged in experiments with a view to establish the manufacture of aluminium in this country, and to produce it at a cheaper rate than hitherto. He has adopted the cryolite process rather than the double chloride of aluminium and sodium, inasmuch as the cryolite is readily obtainable in large quantities and at a very low price. Mr. Gerhard has erected furnaces at Battersea, and there is no reason to doubt that with the modifications which he has introduced, added to the fact that the materials are cheaper in this country than in France, aluminium may be produced here at a still lower price than in France, whence the small quantity that has been used in this country has hitherto been imported. Mr. Gerhard's process he shortly describes as follows:—270 parts by weight of powered cryolite are mixed with 150 parts of common salt, and into this mixture are placed 72 parts of sodium, cut into small pieces. The whole is then thrown into a heated earthenware crucible, previously lined with a melted mixture of cryolite and salt, which mixture is also immediately poured over the contents of the crucible, covering them to some little depth, over which the lid is then placed. The crucible is then put in a furnace, and kept at a high red heat for about two hours. When the pot is uncovered the melted mixture is well stirred, and then poured out. The buttons of aluminium are found mingled with the slag, and may be easily melted together by heating them in a crucible with common salt. Theoretically, the amount of aluminium produced should be one-third of the weight of the sodium employed, but practically such a result is never obtained, and our manufacturers would be well satisfied with obtaining between one-third and one-fourth. This Mr. Gerhard has accomplished, though he is not always so successful. There is still some uncertainty in the process. "From what I have seen, and from what I have learnt from those better qualified to judge on matters of chemistry and metallurgical operations than myself, I am led to believe," said Mr. Foster, "that the cryolite process is the one that will ultimately be preferred to that of the chloride of aluminium." As yet, however, the process presents certain difficulties which Mr. Gerhard appears to have to some extent overcome by his method of performing the operation. Previous to Deville's labours, aluminium sold at the rate of £40 sterling for 35 oz. avoirdupois; and when Deville came to England, in 1856, the result of his labours had then already caused a reduction in the price to £3 per oz. Mr. Gerhard already manufactures sodium commercially, and owing to his labours, the price of sodium has been considerably reduced, being now sold at 16*s.* per pound avoirdupois, while two years ago the price of imported sodium was £6 sterling per pound. Aluminium, imported from France, fetches 7*s.* 6*d.* per oz., and there is no doubt that if large quantities of it were required the supply would be made at once at a considerable reduction on this, which may be termed a retail price. There can be no reason to doubt that at no distant period it will be produced at a cost which will secure its application to numerous important uses. "I may add," said the author, "that while engaged in the preparation of this paper, I have been informed, and I have no reason to doubt the truth of my information, that certain modifications are likely to be introduced into the manufacture of sodium, so as to enable it to be produced at a marvellously reduced price, which will affect in a proportionate degree the cost of aluminium." He next noticed the properties of this remarkable metal. One is its extreme lightness, its specific gravity being 2·6, nearly that of glass, whilst that of platinum is 21·5, gold 19·5, silver 10·5, copper 8·96, zinc 7·2, tin 7·3; and in comparing its price with these metals this quality must be taken into consideration. Thus, if one ounce of silver is required to make a spoon, the same weight of aluminium will make very nearly four. The metal is malleable, ductile, almost without limit; it can be reduced to very thin sheets, or drawn into very fine threads. Its tenacity, though superior to that of silver, is less than that of copper; but no very accurate experiments have been made in this respect. When pure it is about as hard as silver. Its elasticity is not great. It files readily, and is said not to injure the file. It conducts electricity with great facility, so that it may be considered as one of the best conductors known, almost equal in this respect to silver, and more than eight times a better conductor than iron. It melts at a temperature a little above that of zinc, between zinc and silver. In its chemical qualities it would seem to take an intermediate rank between what are termed the noble metals and the common metals, being, as Deville states, one of the most unalterable of metals. It might be imagined that it would as readily re-assume its oxygen as it parted with it with difficulty when in a state of oxide. This, however, is not the case; it appears to be as indifferent to oxygen as either platinum or gold. In air and in oxygen it undergoes no sensible alteration, and it even resists it at the highest temperature which Deville could produce in a cupelling furnace, a temperature higher than that employed in assaying gold. Water has no action, according to Deville, on aluminium, neither at its ordinary temperature nor when boiling, nor even upon the metal at a low red heat, near its melting point. (According to Professor Crace Calvert, this statement must be received with some degree of caution, as he considers that oxydation takes place slowly where the metal is immersed in water for any considerable length of time.) It is not affected by sulphur or sulphuretted hydrogen, like silver, nor is it acted upon to any considerable degree by any of the oxy-acids in the cold; nitric acid, whether strong or weak, at its ordinary temperature, in no way affects it, though when boiling it acts upon it slowly. Small grains of aluminium, plunged in sulphuric acid for three months, remained apparently unaltered. The vegetable acids, such as acetic, oxalic, and tartaric acids, have scarcely any effect on it at all. The true solvent of the metal is hydrochloric acid, which attacks it rapidly. It appears to resemble tin when brought into contact with hydrochloric acid and the chlorides. Its absolute harmlessness permits of its being employed in a vast number of cases where the use of tin would not be desirable on account of the extreme facility with which that metal is dissolved in the organic acids. But the effect of common agents on the metals in general use has been little studied. Aluminium, like iron, does not unite with mercury, and scarcely at all with lead. It, however, forms a variety of alloys with other metals. Looking at the various remarkable properties which this metal possesses, it is impossible not to see an immense variety of uses to which it may be applied. Already its lightness and colour has brought it into use for jewellery and ornaments of various kinds—bracelets, combs, pins, seals, penholders, tops of inkstands, portemonnaies, shirt studs, harness, statuettes, candelabra, candlesticks, &c. Its ductility and fusibility render it readily stamped and cast. It works easily under the graver, and being unaffected by the atmosphere it has an advantage over silver. Its lightness renders it peculiarly fitted for spectacle-frames, eye-glasses, telescopes, and opera-glasses, to which uses it has already been largely applied. It does not stain the skin as silver does. The alloys, too, or aluminium bronzes, as they may be termed, are peculiarly fitted, from the readiness with which they are worked, and their not changing under the action of the atmosphere, for the wheelworks of clocks and chronometers, as well as for the cases, too, for which the metal itself, also from its lightness, is peculiarly fitted. Spoons, forks, drinking vessels, and covers for glass vessels may be made of it, which, even at the present price of the metal, will be much cheaper than silver, while they even possess in a higher degree those qualities for which silver has hitherto been prized. Figuier suggests its use for theodolites, sextants, and surveying instruments which have to be carried by hand, and where, therefore, lightness is important. The adjusting screws of such instruments, which, when made of silver or brass, tarnish from the contact of the hand, might with advantage be made of aluminium. Professor Bleekrode informs me that the working of this metal has, at his suggestion, been taken up by Mr. Meyer, a jeweller at the Hague, who, amongst other things, has had a bell cast, the handle of which, as a casting, is equal to anything hitherto done in silver. Mr. Meyer's experience shows that the metal works well under the hammer, is well suited for chasing and engraving, as well as for casting. He alludes to the want of a proper solder for uniting several pieces, and has been obliged to adopt riveting, as in Paris. It has already been used by the dentist as a substitute for gold, in stopping, as well as for fixing artificial teeth, both on account of its cheapness and lightness, but the accounts differ as to its fitness. The special qualities of this metal render it well adapted for coin; and, as soon as it can be obtained at a sufficiently low rate, it would make an excellent substitute for our copper coinage. Thus assuming that it can be produced for 5*s.* the ounce, the price of silver, then looking at its bulk as compared with silver, any coin the size of silver coin would be worth one-fourth of it, and hence an aluminium coin of the size of a fourpenny-piece would be worth one penny. Its lightness, too, would always render any mistake between it and silver impossible. A piece the size of a shilling would be worth threepence. If the price should get still lower, this would not be of any importance, the coins being tokens only, and not passing at their intrinsic value. That the price will be reduced below five shillings per ounce is a matter which can scarcely be doubted, if we look to the enormous reduction which has been made in a very short time, and when we consider that the manufacture is as yet in its infancy. Let us not despair of its realising the price of copper, when the Master of the Mint would not look upon it with disfavour. Looking at what has already been accomplished in a few years in the production of this metal, both in quantity and price, from £60 sterling per pound down to £6, the present price, and seeing that each day brings with it a further simplification of the process and fresh reduction of price, there is every reason to expect that at no very distant period the metal will be produced in large quantities and at very diminished rates of cost, so as to render it available for an infinity of industrial purposes. Unfortunately, it appears subject to considerable abrasion under friction.

ON A QUICK-WORKING POWER ENGINE.

(*Concluded from page* 158.)

THE MOTIVE POWER.

It being not impossible that, after all that has been said, a reader might still ask the question, the explanation is here given that the motive power at first would be in several deposits of power, by the position of the pistons giving some advantage of gravity in the water, by the tension of the springs, by the pressure of air in a vessel towards a vacuum, and by the bearing off the contents of the perpendicular tapering pipe on the reservoir, and through it against the lower piston which was to be forced up and was to pump down the upper one resisted by general friction only, and that afterwards it would consist in the acquired superiority of the internal force, together with momentum over the resistance.

But this would be perpetual motion giving a surplus of power, to attempt which is universally and proverbially held to be absurd. The absurdity, however, as impossibility is an assumption which, by the laws of reason, cannot be opposed to a legitimate conclusion founded on admitted laws of nature and rules of art. Simple perpetuity of motion is indeed proved to be possible in a model at Woolwich. More was unattainable as long as the experiment was tried solely on the principle of the first law of motion, and the single force relied upon was momentum. But if

Digitized by Google

some intrinsic and gratuitous power can be added to momentum, the two forces together may yield more than is required to perpetuate themselves. Then the power of the hydraulic press is intrisic to it, and is gratuitous in its own nature, though it is created from without, and not gratuitously; which engine, instead of returning less than it received, like all others, returns as much in degree and very far more in amount. And this is the power which would be added to momentum in the proposed quick-working variety.

It may be worth while to point out some analogies between Sir William Congreves' invention of a toy and this invention of a most effective engine. In that invention a polished ball rolls incessantly between opposite angles of a board resting at its middle on a pivot; and by its weight in that later half of its run, causes an inclined plane to be presented to itself, which it descends, and striking against a spring is driven up again, when the process is repeated to the opposite side, where also a spring is placed. The ball may be compared to the current in this engine, and the board to the double pump, though the things are very dissimilar. The running of the ball makes the board incline, and the inclination of the board helps the ball to run; and so the valve would work the double pump, and the pump raise and propel the water. Springs give continuity to the run of the ball, reversing its direction; and so springs would help to change the action of the pistons of the pump, but without reversing the direction of the current.

The difference is most essential, and must be decisive between attempting to produce perpetual motion solely by momentum, and attempting it on the basis of a new mode of creating and applying so vast an intrinsic force as that of the hydraulic press, added to momentum, so that the two powers, both being gratuitous, should together institute a perpetual power. Yet this plan is not primarily an attempt to solve the problem, but the problem of obtaining quick motion in a variety of the hydraulic press; and the solution of one is the consequence of that of the other, owing to the necessity that the engine should displace the water under the piston that was at its highest level, and because this would be very inconveniently done by the superfluous employment of an external force in working the double pump.

FRENCH NAVAL AFFAIRS.

A RELIABLE correspondent favours us with the following letter on French naval affairs, dated Havre, 4th March, 1859. He says:—

"The works for effecting a new and more direct entrance to the New South Docks are progressing rapidly. The north quay of the docks is now completed, and forms a noble platform. If war should unhappily occur, it is to be feared that it will be long ere it be covered with merchandise. The new dredging machine deserves particular notice. This fine vessel, built by M. Mastin, is constructed with a trough in the centre, or rather, she is formed of two vessels joined together, the dredge working between the two, a screw is fitted in the centre for propulsion, she can therefore shift her berth, or go from port to port without requiring the assistance of a steam-tug. It is said that she can be propelled at the rate of six knots. A brigade of barges has been constructed specially for her, with shifting or delivery bottoms, &c. Several of these barges have screw propellers, so that they are likewise independent of steam-tug assistance.

"Two gun-boats have just been completed by M. Norman for the Brazilian Government; the guns were sent from England. They are fine vessels, but rather deep, they are rigged as barques, and armed with three pivot guns (68 pd.) and four broadside howitzers.

"M. Norman has two vessels of war up in frame, the "*Carrara* and *Forfait*," the latter an Aviso 1st class; the construction of the bows of these vessels deserves notice. They are built in solid, that is, the timbers are placed close together, say to fifteen feet aft, forming a solid mass. This peculiar construction suggests the idea that the designer has in contemplation their running stern on into an opponent, on the same principle as the galley combats of olden times.

"The docks are not very full of shipping at present. It is remarkable how common M. Cunningham's system for reefing is becoming amongst the merchant navy of France. Almost every third ship now in the docks is rigged on that system. A few small vessels are fitted with M. Bronard's plan. By the bye, a very interesting trial came off here yesterday at the Tribunal of Commerce—M. Cunningham cited M. Bronard before the tribunal for infringing his patent. The principle of M. Cunningham's invention is, that he employs the gravitation of the yard and appendages as the motive power for producing the necessary rotation for rolling up the sail, which M. Bronard also has, and is, in fact, the vital point of M. Cunningham's plan. M. Blane, Advocate of Paris, appeared for M. Cunningham, and the pleading on both sides was maintained with much vivacity. The judgment will not be known until after the Carnival recess, but the general opinion is, that the sentence will be in favour of M. Cunningham.

"In conversation with a gentleman acquainted with the subject, we were surprised to find that the French ships of war are all using *six-bladed screws*. Now, our efforts have been altogether in a different direction—we have been trying to get the screw as compact as possible, so that when the ship is under sail, the screw shall be hauled up out of the water, which cannot be done with a six-bladed screw!

The old *Porteus* steam-boats with the paddles at the stern, for navigating the Seine up to Rouen, are at last giving place to handy screw steamers; a class of vessel which is also on the increase for the coasting trade."

NOTICES.

THE demand for Mr. E. J. REED's paper—
ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"
has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of nsertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

CORRESPONDENT'S REPLY.

CHIEF ENGINEERS IN HER MAJESTY'S NAVY.—In reply to your correspondent (G. Hogben, at p. 143), I fear there is now no right Royal *route* to become at once a Chief Engineer in Her Majesty's Navy. In years bygone such exceptions occurred at the instance of favourite manufacturers, and engineers were inducted at once into the Royal Navy in charge of pet engines, then imagined to be so dissimilar from all others as to justify such exceptions—a rule, in my opinion, more honoured in the breach than in the observance. A prior period of servitude is required now as an assistant-engineer, averaging some ten years, and divided into three grades, for each of which stringent examinations are (or should be) insisted on, at some one of our naval dockyards; these passed, and the requisite time in each served, the candidate may then present himself at the Steam Department, in London, to pass his examination for his commission; and I believe I may state that a good text-book, to qualify from, would be Brown and Main's Examination Papers. I see no reason, however, that the whole of such period be insisted on, if by giving a better status to the naval engineer young men, who had gained honours at some one of the competitive examinations inaugurated by the Society of Arts, could be induced to join Her Majesty's service. Such could, however, in our opinion only be effected by pruning off some of the rough branches, an excision that must be resorted to ere the corps under consideration he recruited with none but young, well-educated officers.—*X. Y. Z.*

LONDON FIRES IN 1858.

TWENTY-EIGHTH ANNUAL REPORT.

By Mr. WM. BADDELEY, *C.E., Inventor of the Portable Canvas Cisterns, Farmers' Fire-engine, Improved Jet-spreaders, &c.*

"The statistics of London fires are by no means devoid of interest, and the time may come when they will form an index to the social advancement of the people; for, in proportion as houses are built more and more fire-proof, and habits of carefulness become more and more diffused, the number of destructive fires will assuredly lessen."—*Knight's London.*

(*Continued from page* 175.)

AMONG the more notable fires of the year the following deserve a passing notice:—

Sunday, January 3rd, 2 A.M.—A most extensive fire broke out in the premises of Mr. Thompson, boat-builder, Horse-ferry-stairs, Rotherhithe. The fire began, from some unknown cause, in the centre of this extensive range of premises, and for a time raged with a fury that defied opposition. The highly combustible nature of the stock, the distance of the fire-engine stations, the uncertainty as to which side of the river was the locale of the conflagration, and the deficient supply of water when the engines reached the spot, all contributed to aggravate the mischief. On the arrival of the two steam floating engines, however, a vigorous and successful attack was made upon the destroying element, seconded by the operations of a few land engines that were set to work from the sewers, and the spread of the fire was arrested, but not until the following damage had been done:—Two timber buildings, two storeys high and 160 feet deep, with their contents destroyed; the stock of timber and boats, finished and unfinished, very severely damaged; the windows of dwelling house burned out, and rest of building and furniture damaged. Large timber building of Mr. Thomas, shipwright, destroyed. Private residence of Captain Smith considerably damaged; and the old stores of Mr. Marshall, shipowner, partially destroyed. The reflection of this fire was visible at a considerable distance from the metropolis; it was plainly seen at Romford, on the one hand, and Windsor, on the other.

Tuesday, January 12th, 2½ A.M.—A most destructive fire broke out in the General Steam Navigation Company's works at Deptford-creek, which was not extinguished until a store warehouse of two floors, about 120 feet long by 36 feet wide, was destroyed; the sail makers' and turners' shops, loft, and roof, were considerably damaged.

Saturday, January 30th, 8½ P.M.—A fire took place on the premises of Mr. Athell, timber merchant, Elizabeth-street, Hackney-road. These premises were of considerable magnitude, comprising veneer rooms and sundry other buildings containing a valuable stock of mahogany, rosewood, &c., while the open yard was filled with piles of deal and other timber, all of which were nearly destroyed. Five houses in Elizabeth-street, and the parsonage house in St. Peter's-street, were more or less damaged.

Wednesday, March 10th, 8½ P.M.—A fire took place in the warehouse of Mr. Parker, wholesale mantle manufacturer, Monkwell-street, Cripplegate. The fire was soon extinguished, and appeared to have been wilfully occasioned, by pulling a gas bracket away from the stanchion to which it had been screwed, and bending it up so to cause the flame to act upon the under side of the shop flooring, which was soon burned through, and the flames were rapidly spreading when their progress was arrested. Mrs. Parker and the children left the house in the afternoon, and about 8 o'clock, or soon after, Mr. Parker sent the servant girl for some beer, but did not wait her return, she consequently could not get in, and the premises were found to be on fire. Mr. Parker had effected an insurance in the Westminster Fire Office for £1,000, and after the fire sent in what was considered an exaggerated claim; and the whole of the circumstances were so suspicious, that Mr. Parker was taken into custody on a charge of arson, and committed for trial, which took place at the April sittings of the Central Criminal Court, and lasted two days. After the evidence for the prosecution had been given, Mr. Parry for the defence, "admitted that the case was one of suspicion, but that the origin of the fire was involved in so much doubt, that a conviction could not safely follow, and if that conclusion was arrived at, then the exaggerated claim that was alleged to have been made did not effect the case;" the jury ultimately returned a verdict of "Not guilty."

Monday, April 5th, 9½ P.M.—A fire broke out in a very old house in the occupation of Mr. Soléme, shirt-maker, No. 28 High-street, Aldgate. Fire-escape conductor Cook immediately entered a front window and searched the house, but found it wholly destitute of inmates, and nearly so of furniture. Shortly after the arrival of the engines, the building fell down, and the fire was extinguished. Mr. Payne, the City Coroner, having received a numerously-signed requisition to that effect, held a court of inquiry into the origin of the fire. Mr. Hodsoll, the assessor, stated that the premises were insured in the Liverpool and London Fire Office for £600, the stock-in-trade, furniture, &c., for £700, making a total of £1,300. After carefully sifting the ruins he estimated the value of the stock and furniture to be worth at most but £39! Mr. Soléme had several times spoken of "making his fortune by fire or water," and of setting fire to his house, "when he would get £1,200 from the insurance office, and then he would go to St. Petersburg." A female witness, who had been standing opposite the house twenty minutes, saw two persons come out, whom she identified as Mr. Soléme and Mr. Goldberg, and immediately afterwards saw the shop was on fire. After an able summing up by the coroner, the unanimous verdict of the jury was, "that the premises were wilfully set on fire by the two persons who were seen

Digitized by Google

to come out of the house, but who those persons were there was not sufficient evidence to prove."

Tuesday, April 27th, 7¼ P.M.—A fire broke out in the upper floor of the E warehouse, St. Katharine's Dock. These warehouses were six storeys high, and built on arches, every floor being filled with merchandise of great value. A powerful force of engines was soon brought to bear upon the seat of the fire, and by midnight its further spread was prevented. The sixth floor of the E warehouse, and atties, were burned out, the roof off, and serious damage to the contents on floors under by the immense volumes of water that were thrown upon the flames.

Saturday, June 19th, 9¼ P.M.—A very serious conflagration, which is supposed to have been occasioned by a cinder from a locomotive engine, broke out in the extensive premises of Messrs. Forrest, Norway Wharf, Commercial-road, Limehouse, which at the time contained a large number of ships, boats, and vessels of great value, as well as several life boats, recently finished for noblemen, and one for the Emperor of Russia. The fire raged with great fury for several hours, destroying three ranges of workshops, 200 feet long by 120 feet wide, the cottage, counting-house, boats, and immense stock of timber in open yard. The flames also entered the premises of Messrs. Dixon, timber merchants, and nearly consumed the whole of their stock. A similar loss occurred to Messrs. Dalton and Co., mast-makers, their stock of timber in open yard being all but destroyed. Six arches of the Blackwall Railway, and several adjacent buildings, were also severely damaged.

Monday, June 21st, 7¼ A.M.—A fire, involving a great destruction of property, broke out at Fresh wharf, Lower Thames-street. The premises formed a block of three warehouses about 130 feet wide, and six storeys (nearly 80 feet) high. The fire commenced in the middle floor of the centre warehouse, known as the silk floor. With as much promptitude as possible a strong force of engines, including the two steam floating engines, was brought to bear upon the fire, and by mid-day it was thought that any further extension of the flames had been averted. Unfortunately, however, the fire was found to have entered the eastern warehouse, and the conflict was renewed for several hours, when the flames eventually succumbed to the overwhelming force brought to bear upon them. On examination it was found that the three upper floors of the middle warehouse, with their valuable contents, were seriously damaged by fire; the three upper floors of the eastern warehouse were similarly damaged, the lower floors and contents being damaged by water. The third floor of the west side of the east end warehouse and contents was also damaged by fire, water, and hasty removal.

Tuesday, June 29th, 11¼ A.M.—A fire broke out in one of the South Quay warehouses of the London Docks, between the Hermitage and Wapping river entrances. Although termed one warehouse, it had numerous divisions, separated by thick party walls, communicating on each floor by strong iron doors. On the alarm of fire being given, the Dock Company's land and floating engines were brought to the spot, followed by that of the parish of St. John's, Wapping, one from Messrs. Hore's brewery, ten of the brigade and their two steam floating engines, as well as the West of England engine. This powerful force was brought to bear upon the seat of the fire, which, for a time, extended rapidly to the various floors until it reached the saltpetre, when a tremendous explosion took place, by which the centre division of the building was blown to atoms, the division walls forced in, and the floors of the adjoining warehouses fired. Happily, no person was injured by the explosion, and for hours the firemen worked with unflagging energy, and by six o'clock the fire was vanquished, when it was found that the centre warehouse was destroyed by fire and explosion, the upper floors of two warehouses adjoining destroyed by fire, and the lower floors seriously damaged by water.

Sunday, July 25th, 11½ A.M.—A fire broke out in the premises of Messrs. Rolt and Co., timber-merchants, Acorn-wharf, Rotherhithe, covering an area of ground nearly 400 ft. long by 30 ft. wide, filled with piles of timber from 70 to 80 ft. high. The cause of this disastrous fire was a chimney on fire at Mr. Goss's, in Trinity-street, some sparks from which fell among the timber in Messrs. Rolt's premises. Before any effectual assistance could reach the spot, the flames had made great progress. The floating engine from Deptford Dockyard, the two steam floating engines of the brigade, as well as six land engines, and that of the West of England office, were brought to the spot as quickly as possible, but for a time produced but little effect upon such a vast body of fire, which was not extinguished until the following damage had been done:—Messrs. Rolt's deal wharf, and three barges laden with timber alongside, all but destroyed; three brick and timber buildings in Trinity-street, the property of Government, burned down; and ten houses in Trinity-street damaged. This was not, however, the full extent of the fire, for the gale that was blowing at the time carried the shower of sparks across the river, and ignited the rope-works of Messrs. Fowler and Smith, Millwall, the engineers' shops of Messrs. Seaward and Co., Canal Ironworks, as well as the *Camperdown*, lying in the dry dock of that firm. At Messrs. Fowler and Smith's, about 300 ft. of sheds, including mill-house, machinery, and stock, were destroyed—and all through "a chimney on fire!"

Thursday, August 5th, 2½ A.M.—A most destructive fire occurred in the premises of Mr. Harrison, tanner, Willow-walk, Bermondsey, which rapidly extended to those of Messrs. Chisholm and Co., chemical and manure works; Messrs. Almond and Co., army contractors; and Mr. Hawes, fellmonger. The whole of this property, covering several acres of ground, became speedily ignited, and raged for a time with uncontrolled fury; for, although a strong force of firemen and engines soon arrived, upwards of half an hour elapsed before the Southwark Company's mains yielded any water. By seven o'clock, however, the apprehension of any further spread of the fire was at an end, and all that remained was to cool the smoking ruins.

Friday, August 13th.—At midnight a fire broke out in the premises of Mr. Emery, shipping and general cooper, in Brunswick-street, Blackwall. The property covered nearly half an acre of ground, on one side stood a number of lofty cooperages, and in the open yard were numerous stacks of prepared timber and immense piles of hoop sticks. Soon after the fire commenced it seized hold of seven of the cooperages, and then swept round the stacks of timber in the yard, all of which were destroyed; the roof of another cooperage adjoining and its contents, as well as seven adjacent buildings, were damaged.

Sunday, October 3rd, 3½ P.M.—A fire broke out in the extensive premises of Mr. Westhorp, ship rigger, near the West India Docks, Poplar. These premises consisted of the upper floor of a one-storey building, 200 feet long by 16 feet wide; the ground floor was occupied by Messrs. Bell and Wright (also ship riggers), as was also six arches of the Blackwall Railway, and there is no doubt that a cinder from a locomotive engine thrown into the premises was the cause of the fire. Each department was filled with ship's furniture, stores, and costly machinery, and from the combustible character of the premises and their contents the flames for a time defied opposition; they were, however, eventually extinguished, when a fearful amount of damage was found to have been done.

Just before 9 o'clock in the evening of Monday, December 20th, a fire broke out in a van belonging to the Great Western Railway Company as it was standing loaded with parcels, in New Oxford-street. The horses were at once detached, the van drawn up to a pump, and the fire put out by the firemen who arrived with their hand-pumps. The packages (for the most part Christmas presents) rapidly disappeared, and many of them were received where they were neither directed nor expected. The cause of the fire was supposed to be unextinguished tobacco falling between the packages From a similar cause, a pleasure van returning from Hampton Court in June last, took fire while crossing Clapham Common, and two of the female excursionists were very seriously injured.

About an hour before midnight on the 4th of December, a false alarm of fire, which caused a general turn-out of the fireman and engines, was occasioned by the sudden appearance of a brilliant red light in the sky in a northerly direction, which almost everybody supposed to be the reflection of a most extensive conflagration, but which was ultimately discovered to be a brilliant display of the Aurora Borealis.

(To be continued.)

ERRATA.—In Fire Report, page 154, third column, 22nd line from top, for "bleaching *rats*" read "bleaching *nuts*." Page 175, second column, 33rd line from bottom, for "The was" read "There was."

Our Weekly Gossip.

A singular excursion is said to have been organized at Antwerp—no less than a scientific and industrial voyage round the world. A vessel, it is said, is being fitted up for the accommodation of passengers, their instruments, scientific collections, and mercantile speculations. The programme is, to sail from Antwerp at the end of March, touch at Lisbon, thence sail to the Cape de Verde Islands, the Cape of Good Hope, Siam, Cochin-China, Java, Singapore, Hong-Kong, Canton, Jeddo in Japan, the Kurile Islands, and the Russian Settlements on the Amoor and in the Gulf of Ochotsk, returning by way of San Francisco, Lima, Valparaiso, Patagonia, the Straits of Magellan, Rio de Janeiro, and thence back to Antwerp. The price for the whole voyage, including provisions, is 4,000 francs (about £160) for each cabin passenger. The expedition is calculated to occupy fourteen months.

Messrs. Fox and Chesterman, the well-known steel-makers, of Sheffield, have this week terrified us with specimens of an improved make of steel, especially adapted for ladies' crinolines. This material is so light, so elastic, so easily fitted, and withal so strong, that we fear it will be likely to prolong a very bad fashion—a fashion which injures the health of one sex, destroys the comfort of the other, and corrupts the morals of both. The improved steel is hardened by a new process, and is corrugated transversely, whereby not only is its liability to breakage reduced, but great facilities are afforded for lengthening or shortening the hoops, as the fancy of the fair wearer may dictate—not, alas! as the peace or comfort of *man* may require. With all respect for the ingenuity of the Sheffield firm, we must say we regret to see them aiding a fashion which is doing society no good whatever.

The French papers state that five French frigates are about to be sheathed with thick iron, so as to make them shot-proof. The contract for one is said to be just concluded. What a pity it is that a little information respecting the mode in which this is to be done is not *vouchsafed to us* especially as we do not believe it to be at all practicable to operate upon ordinary frigates as proposed.

The official report of the Admiralty on the Falmouth Docks and Harbour Bill states that the following works are proposed:—A dock of 8 acres area; a tidal harbour of 12 acres; two patent slips, each 400 feet ong; and a channel leading from the sea to the tidal harbour, 2,780 feet in length, with a medium width of 400 feet at the bottom, and 18 feet depth at low water. The tidal space proposed to be occupied by the dock and basin is at present very shoal, having only a depth of about one fathom at low water, so that vessels of any size must ground. Under these circumstances the construction of a floating dock of eight acres with a depth of 21 feet, and a tidal basin of 12 acres, with a depth of 18 feet at low water, must, the report states, prove of great importance to the trade of the port, and especially to steamers; their lordships, therefore, consider that the scheme deserves the approval of Parliament. The amount to carry out the undertaking is fixed at £200,000, with power to borrow one-third more.

On Saturday last, Captain Norton attended at Brompton barracks, Chatham, for the purpose of making some further experiments with his liquid-fire rifle shells. In the experiments made on Saturday a liquid-fire rifle shell, adapted to a deep-grooved Enfield rifle, was fired from a pistol, rifled with the deep grooves, into canvas suspended at the end of the range. On the shell striking the canvas the glass containing the liquid fire was immediately broken, and the piece of canvas almost instantaneously became ignited. The result of the experiment proved that similar shells constructed by Captain Norton may be fired at long ranges from the ordinary Enfield rifle, for the purpose of blowing up the ammunition trains, or setting fire to the camp of an enemy. Captain Norton has presented specimens of these shells to the museum of the United Service Institution, where they can be seen.

Mr. Whitworth writes to the *Times* a letter which entirely confirms the remarks we made in our last number. "Would you allow me," he says, "an opportunity of correcting the impression which I find has got abroad, that cannon made by me have failed in practice? As this impression may, perhaps, be strengthened by the report of the observations made in the House of Commons last week, I feel myself called upon to state the facts that have given rise to reports which are really without foundation. My experiments have for some time past been mainly directed to the subject of rifled small arms; but, as the system which I have adopted is equally applicable to ordnance of all sizes, I bored and rifled several pieces of cannon, which were supplied to me in the solid by the Government. Some of these were brass guns, which have stood the test of continued firing, and three were of cast iron, which have burst. For the strength of these guns I was in no degree responsible; they were the ordinary pieces made for the smooth-bored cannon used in the service, and proved too weak to bear the strain of firing long rifled projectiles. I should most certainly not have undertaken to rifle them if I had foreseen, or could have supposed that their failure, which was caused by want of strength, would have been imputed to my system of rifling. Being desirous of immediately rendering all the aid I could to the service, I considered the experiment of rifling the pieces, as they are ordinarily supplied, worthy of being tried, and I think I may venture to state that their trial has furnished results of no inconsiderable importance. All the guns rifled by me belonged to and were at the time at the disposal of the War Department. I had not the means of firing cannon at long ranges, but I hoped to have been furnished with the results of experiments that would have enabled me to form correct conclusions. I hope soon, however, to be enabled to make trial of two guns which, on my own respon-

Digitized by Google

sibility, I am constructing of the requisite strength, and which, I doubt not, will fully realize the expectations entertained by those who witnessed the first experiments in April, 1856, with the 24-pounder brass howitzer which I bored and rifled. At that time projectiles varying from two to six diameters in length, having quick rotary motion, were fired with great success."

Great preparations for the coming Handel commemoration festival at the Crystal Palace are in progress. From a programme issued by the Company we learn that the orchestra will be enlarged to the full width of the transept, viz., 216 feet, with a central depth from front to back of about 100 feet. Its extent will be more clearly appreciated when it is stated that its width is exactly double the diameter of the dome of St. Paul's cathedral, that it possesses a larger area than the combined orchestras of Westminster Abbey (as arranged for the commemoration of 1784), York Minster (as at the festival of 1823), the Birmingham Town Hall, the Leeds Town Hall, St. George's Hall, Bradford, the Philharmonic Hall, Liverpool, and some other smaller orchestras. But it is not from the mere augmentation of extent that the most favourable results are anticipated. The additions are mainly based upon a recent alteration of the orchestra at Exeter Hall, which has been attended with the happiest effect; and every confidence is felt that these modifications in the general plan, with certain acoustic improvements, will result in greatly increased concentration and unity of tone. At the same time the appearance of the orchestra will be materially improved by its more perfect proportions, and by the decorations which it is proposed to adopt.

Mr. Allan has explained in detail to a party of gentlemen assembled at the Town Hall, Manchester, his views with reference to the cable which he proposes should be laid in the Atlantic. Mr. Allan stated he was from the first convinced that a cable of the weight of that which had been laid down across the Atlantic could not be submerged in deep water without being strained, the result being the impairing of the insulation. In shallow water a light cable would be unsuitable, but on the other hand it was the only one suitable for deep water. In the construction of the light cables there was a saving of 40 per cent., and this saving he proposed to apply towards increasing the conductibility and insulation. His cable was composed of one solid wire of copper, covered with wire strands, over which were three layers of a material composed of gutta percha and another substance. Gutta percha alone might yield from the warmth of a ship's hold, but the mixture made it as tough as leather, and capable of resisting heat to the extent of 150 degrees. Little more than two hours would be occupied in sinking 2,000 fathoms of his cable, which he proposed to submerge in almost a horizontal position, so that the danger of straining would be escaped. The cable laid last autumn weighed 21 cwt. to the mile, but the weight of his was only 8 cwt., so that a vessel of 1,200 tons could take the whole length. The breaking strength in air of the new cable was not more than half that of the old one, but in water the difference was greatly reduced. The cost of his proposed new cable Mr. Allan estimated at £100 per mile.

Mr. Andrew Lamb, engineer, of Southampton, and W. J. White, of Cowes, have introduced several improvements into the construction of life-boats. They form the boat with longitudinal water-tight compartments on each side, and extending nearly from stem to stern, "the centres of gravity and displacement of which (should the life-boat be filled by a sea)," say they, "are so high as to make it almost impossible for the boat to be capsized." They introduce two or more delivery tubes, with valves so constructed as to prevent the admission of water from without, and to free the boat from the water within down to the level of the water outside; and "we so place and arrange the tubes," say they, "with reference to the calculated centres of gravity and displacement of the boat, as to make her available for carrying out the largest anchor from the ship, the anchor being slung under the bottom of the boat, and (being a life-boat) should she ship a sea, there will be sufficient buoyancy in the air-tight compartments to carry the anchor and crew with safety, whilst an ordinary boat would be buried by the waves, and consequently sink." These valves will also admit air, should such a contingency as the boat's capsizing occur, and the crew be confined underneath, where they would be safe, there being sufficient head room for them beneath the thwarts and the bottom. In addition to the water-plugs at the lower part of the air cases, they introduce screw-plugs at the top of the water-tight compartments, by which a free current of air may be passed through the cases to ensure their durability.

With reference to the obstructions in the Nene—in regard to which paragraphs have appeared for several weeks past—it appears that the Wisbeach Town Council have given the Nene Valley Commissioners formal notice to remove the dam at Guyhirn. The complete removal of the partially-destroyed dam at Waldersea has been entrusted to Mr. Marshall, who has undertaken to perform the work for £175. Mr. Page, C.E., has received instructions from the Wisbeach authorities to make a survey of the Nene from Peterborough to the sea, and to report what is best to be done with a view to secure the interests of all the parties concerned in the drainage, navigation, and water-supply.

A Mr. Prisley, of Walworth, has patented a method of advertising on ordinary street-lamps, which we hope will *not* come into general use. He first removes the top or upper part of any of the lamps or lanterns now in use for lighting streets and other public thoroughfares, and affixes to the lamp, in the place of its ordinary top, an addition or elongation, on which the name of somebody's hats, or pills, or coffee, or other necessaries or luxuries of life, is blazoned.

The *Critic* of Saturday last says:—"In a lecture recently delivered at Chelsea by Mr. Gilks, the following curious statistics were communicated concerning the illustrated press. Of ten illustrated papers published in London every week, viz., the *Illustrated London News*, *Illustrated Times*, *Punch*, *London Journal*, *Reynold's Miscellany*, *Cassell's Paper*, *Leisure Hour*, *Sunday at Home*, *Town Talk*, and *Mechanics' Magazine*, the aggregate circulation is 1,744,000 copies per week, and the weekly cost of engravings is £578; making a total annual circulation of 90,688,000 copies, and spending £30,056 per annum upon engraving."

Mr. W. Pursell, of Birmingham, is introducing an improvement in the manufacture of percussion caps. The caps having been charged with the detonating composition, the metallic or other powder is dropped in through perforated plates, similar to those which are used at present for charging. This powder is then subjected to sufficient pressure or friction to coat the surface of the detonating composition therewith, thus rendering the coating impervious to moisture, and protecting the detonating composition from injury by exposure to damp and wet.

Mr. H. C. Jennings, of Great Tower-street, London, proposes to manufacture an artificial parchment from fish, and then convert the parchment into leather. He exposes fish (the commonest or refuse sort), after the offal and skins are removed, to the action of dilute solutions of soda ashes, crystallised soda of commerce, or carbonate of potassa, and then to a solution of hydrochloric acid. The mass is then pulped, washed over sieves to remove the bones, &c., drained or pressed, and then saturated with a weak solution of bichloride of mercury. After this it is thoroughly washed to remove the salts employed, is formed into sheets by the ordinary means used by paper makers, and is then rolled or pressed to equalise the surface. To convert the parchment thus made into leather, he uses solutions of oak-bark, terra japonica, or any of the substances employed by tanners. But for particular purposes, and for a more perfect article, he employs solutions of ammoniated alumina, or aluminated potassa, muriate of soda, and nitric acid; and the sheets, after saturation, are immersed in a solution of dilute oxalic or hydrochloric acid, and then returned to the alumina solution, and so on alternately until the gelatine and fibre are rendered perfectly insoluble.

The *Manchester Guardian* of Wednesday week has the following:—Those who are interested in the extended growth of cotton may see, at the office of the Cotton Supply Association, or at the works of Mr. Dunlop, an adaptation of the M'Arthy roller-gin to cottage use. This gin undoubtedly frees cotton from seeds and dirt more effectually than any other, and gets through a larger quantity, in a given time, with the same power. That for the cottage is turned by two persons, at a speed of 680, and cleans fully 10lb. per hour. It preserves the fibre intact, instead of chopping it, and rendering it both shorter and of irregular length, which is the great fault of the saw-gin. It is less liable to injury than the saw-gin; and, as it is divisible into small parts, it may be easily carried, on men's shoulders or on the backs of animals, from the ports, and along bad roads or no roads, into the interior of India or of Africa. This adaptation—devised by Mr. Dunlop, the maker of the M'Arthy gin—is of great importance as regards those countries in which cotton is grown by small and poor cultivators of the soil.

CAPTAIN NORTON'S SPINSTER—"EYE OF NEWT."—"The question has often been asked of me, by what *charm* I insure the layers of match attached to the bottom of the spinsters to be ignited by the fire of the cartridges—I insure it by placing within the layers a small hollow glass ball containing sulphuric acid, and surrounded with the powder chlorate of potash, and sulphuret of antimony. A disc of hard pasteboard is placed on the heads of the cartridges, and this being pressed against the glass shell by the explosion of the cartridge, crushes it, and thus the layers of match are sure to take fire in passing through the air. This plan is best adapted to breech-loading rifles. —J. NORTON."

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated February 1, 1859.

290. G. A. Waller, of Dublin, Brewer. Improvements in the means of, and apparatus for, expressing liquid from semi-fluid substances and other substances containing liquid.

Dated February 10, 1859.

380. B. Burrows, of Leicester. Improvements in looms for weaving narrow fabrics.

Dated February 16, 1859.

438. J. S. Benson, of Birmingham, Merchant. A new or improved method of silvering glass. A communication.

Dated February 19, 1859.

466. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in machinery for doubling threads. A communication from A. Bonez, of Paris.

Dated February 21, 1859.

476. A. Taperell, of Moorgate-st. Improvements in compositions or compounds used when cleaning glass.

478. J. Schloss, of Cannon-st., Manufacturer. An improvement in locks or clasps for porte-monnaies, pocket-books, bags, and other like purposes. A communication.

Dated February 22, 1859.

488. W. Gossage, of Widnes. Improvements in the utilization of alkali-waste.

Dated February 23, 1859.

490. S. Ridge, of Hyde, Millwright. Improvements in coupling or making the joints of pipes and other articles.

492. G. Davies, of Serle-st., Lincoln's-inn. Improved apparatus applicable to the evaporation of saccharine liquids, and for the concentration of heat for other purposes. A communication.

494. W. Sharp, of Bingley, York, Worsted Spinner. Certain improvements in machinery for spinning and twisting worsted, cotton, silk, and other fibrous materials.

496. S. Russell, of Sheffield, Metal Manufacturer. An improvement in the manufacture of handles for tea and coffee pots, jugs, kettles, knives, daggers, and forks, or any other description of article to which handles are applied.

Dated February 24, 1859.

499. J. Robinson, of Lower House, near Burnley, Manager. Improvements in machinery and apparatus applicable to machines for spinning and doubling.

Digitized by Google

500. R. Mushet, of Coleford, Metallurgist. A new metallic compound or alloy.

501. R. Mushet, of Coleford, Metallurgist. An improvement in the manufacture of cast steel.

503. J. Crosland, of Huddersfield, Manufacturer. Improvements in looms for weaving textile fabrics.

504. A. Lançon, jun., of Basançon, France, Watch Maker. A new system of watches.

505. J. H. G. D. Wagner, of Paris, Manufacturer. Apparatus for cleaning water, and removing all matters in suspension and dissolution contained in it, water intended to feed generators of all sorts (applicable also to other purposes), which besides previous to its getting into the generators, is heated to the highest degree without almost any expense.

506. J. Dale, of Cornbrook, Manchester, Manufacturing Chemist. Improvements in concentrating caustic alkalis, and in applying a product therefrom to the purpose of obtaining motive power, and to other purposes.

507. E. Price, of Doncaster, Railway Contractor, and E. Hawkins, of the same place, Builder. Improvements in the mode of forming fish plates, and in the method of fixing or attaching them to the joints of rails on railways.

508. A. C. Keily, of Silchester-road, Notting-hill, Gentleman. Improvements in apparatus for drawing-off fluids.

Dated February 25, 1859.

509. A. Reid, of Manchester, Merchant, and R. Tonge, of the same place, Manufacturer. Certain improvements in weaving, and in the machinery employed therein.

510. A. Reid, of Manchester, Merchant, and R. Tonge, of the same place, Manufacturer. Certain improvements in, or applicable to, looms for weaving.

511. T. C. Hinde, of Dudley, Iron Merchant, and G. J. Hinde, of Wolverhampton, Merchant. Improvements in coating iron with copper, or alloys of copper.

513. W. McNaught, of Manchester, Engineer. Certain improvements in steam engines, particularly applicable to compound steam-engines.

514. R. Fielden, jun., and T. Fielden, of Walsden, Lancaster, Paper Manufacturers. An improvement or improvements in the manufacture of pickers to be used in looms for weaving, and also in the machinery or apparatus to be employed in the manufacture of the same.

615. J. Reddie, of Fulham, Gentleman. An improved mode of propelling and steering vessels.

517. W. Clark, of Chancery-lane. Improved apparatus for spinning, twisting, doubling, and drawing fibrous materials. A communication.

Dated February 26, 1859.

518. F. Weekes, of Bolney, Sussex. The treatment of certain alcoholic products.

519. G Earnshaw, of Horbury, near Wakefield, Millwright. The treatment of woollen and other rags and waste of fibrous substances, so as to obtain useful products therefrom.

520. J. Lee, of Saint Helen's, Grocer. Certain improvements in ploughs.

521. J. Hine, of Clerkenwell, Cabinet Maker. An improved joint for cabinet making, carpentry, and other constructive purposes.

522. W. Burgess, of Newgate-st., Agricultural Implement Maker. An improvement in reaping and mowing machines.

Dated February 28, 1859.

523. E. Gatwood, of Great George-st., Westminster, Carriage Builder. Improvements in buffing traction and bearing springs, applicable to railway carriages and locomotive engines.

525. A. Martin, Merchant, and A. Crichton, Mechanic, of Pollokshaws, Renfrew. Improvements in weaving and woven goods.

526. J. Howden, of Glasgow, Engineer. Improvements in machinery or apparatus for cutting, shaping, punching, and compressing metals.

527. J. Leigh, of Manchester, Surgeon. Improvements in the purification of coal gas.

528. G. Horner, of Belfast, Machinist. Improvements in hackling flax and other fibrous materials, and in machinery for the same.

529. J. H. Johnson, of Lincoln's-inn-fields. Improvements in apparatus for stopping horses. A communication.

530. J. H. Johnson, of Lincoln's-inn-fields. Improvements in apparatus for taking soundings, applicable also to the throwing of life-lines. A communication.

531. C. Hall and C. Hall, jun., of Navestock, Essex, Agriculturists. Improvements in steam agricultural machinery.

532. A. Turner, of Leicester, Elastic Web Maker. Improvements in the manufacture of elastic fabrics.

533. A. V. Newton, of Chancery-lane. Improvements in constructing and working condensing engines. A communication.

534. W. Hodson, of Hull. Improvements in rotatory engines.

535. R. Brown, of Earith, near Saint Ives, and W. Milne, of Bushey, Herts. Improvements in fire-arms.

Dated March 1, 1859.

537. T. Cloake, of Walworth, Watch Maker. Stopping of the bodies and wheels of railway and other carriages.

538. J. Holroyd, of Leeds, Cloth Finisher. An improvement in finishing woollen cloths and cloths made from a combination of wool and other materials.

539. Rev. H. Moule, M.A., of Fordington, Dorset. Improvements in apparatus applicable to the evaporation of sewage or other waters, and for affording heat for other uses.

540. J. Wetherilt, of Mayfair. Certain improvements in locks.

541. J. Edwards, of Fenton, Stafford, Manufacturer. Improvements in stacking or holding biscuit, earthen, china, and glossed ware for firing.

542. G. P. Rivers, Baron Rivers, of Rushmore Lodge, Wilts. An improved implement for breaking up and preparing land.

543. J. Templeman, of Glasgow, Artificial Fuel Maker. Improvements in the manufacture or production of artificial fuel.

544. J. Pile, of West Hartlepool, Ship Builder. Improvements in the construction of floating docks.

545. D. Lichtenstadt, of Peckham, Chemist. Converting certain vegetable substances into fibrous materials for the manufacture of paper, textile, and other fabrics.

Dated March 2, 1859.

547. P. Currie, Brass Founder, of Birmingham. Certain improvements in spindles for locks, latches, and other door-fastenings.

549. J. M. Adams, Gentleman, and D. Law and J. Inglis, Iron Founders, all of Glasgow. Improvements in fireplaces, grates, ranges, and stoves.

551. W. F. Dearlove, of Dartmouth-st., Westminster. An improved chopping machine.

553. J. W. Harker, of Upper Barnsbury-st., Islington, and J. K. Field, of Upper Marsh, Lambeth. Improvements in coating the bottoms of iron and other ships and vessels. A communication.

555. C. Hill, of Cheddar, Somerset, Stay Maker. An improved construction of stay fastening.

557. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the construction of grease boxes and bearings generally. A communication.

559. J. Newcomb, of Bristol, Engineer, and J. G. Lovell, of Bristol, Merchant. Improvements in obtaining and applying motive power, especially adapted, amongst other purposes, to the propelling of ships and vessels.

561. W. Brown, of Edgar-place, Mile-end, Pipe Maker. Improvements in the manufacture of pipe mounts or stems, cigar tubes, and similar articles.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

569. H. Leonard, of Massachusetts. An improvement in the manufacture of paraffine candles. Dated March 3, 1859.

570. W. Tucker, of Massachusetts. An improvement in bit stocks or auger handles. Dated March 3, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, March* 15, 1859.)

2453. V. Blumberg. Billiard tables.
2461. J. Oxley. Carriages.
2467. R. A. Brooman. Motive power. A communication.
2468. I. Baggs. Telegraphing
2474. E. Rowland and J. Dewhurst. Steam engines and valves.
2481. H. N. Penrice. Tunnelling.
2485. J. Cliff. Kilns.
2495. J. Wardill. Purchases.
2496. T. MacSweney. Steering apparatus.
2497. W. Hale. Rockets.
2503. J. S. Dawes. Machine for cultivating land.
2504. J. F. Dickson. Permanent way.
2507. A. Henderson. Vessels.
2515. R. A. Brooman. Telegraphing. A communication.
2516. R. M. Ordish. Permanent way.
2520. W. G. Taylor. Preparing skins.
2522. E. Humphreys. Steam engines and boilers.
2527. C. T. Judkins. Gas regulators.
2529. J. and W. Lees. Oil cans.
2531. F. H. Maberly. Ships and other vessels.
2535. J. Rae. Cisterns.
2541. D. Turner. Wood soles for clogs.
2543 M. N. Mills and N. Sidebotham. Looms.
2544. J. Benyon and J. W. B. Bowden. Looms.
2560. T. R. Butcher, F. Stevens, W. T. Johnson, and T. Jarvis. Pianofortes.
2562. G. Davies. Pile fabrics. A communication.
2597. W. Clark. Bridle. A communication.
2600. E. Briollet. Obtaining caloric. A communication.
2738. E. Jones. Coke.
2964. R. Hornsby, jun. Ploughing and tilling land.
159, W. A. F. Powell. Stopping jars.
175. T. Greenwood and J. Batley. Gassing fabrics. A communication.
290. G. A. Waller. Expressing liquid.
291. M. Loam. Raising sewage, &c.
328. J. Honeyman. Ships; propellers.
329. A. Barclay. Telegraph ropes; paying out the same.
368. G. Bower. Gas.
380. B. Burrows. Looms.
391. J. Grimes. Beer-engines.
405. R. Bell. Separating wool.
468. G. Paul. Spindles and flyers.
469. O. Blake. Glass.
477. R. W. Johnson and W. Stableford. Axle boxes.
478. J. Schloss. Locks or clasps. A communication.
481. J. Grimond. Treating jute.
485. E. Lund. Umbrellas and parasols.
503. J. Crosland. Looms.
522. W. Burgess. Reaping and mowing machines.
527. J. Leigh. Coal gas.
530. J. H. Johnson. Taking soundings. A communication.
538. J. Holroyd. Finishing cloths.
569. H. Leonard. Paraffine candles.
570. W. Tucker. Auger handles.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 11, 1859.

2004. J. M. Courtauld.
2065. H. Page.
2069. L. Kaberry and T. Mitchell.
2074. C. W. Siemens.
2075. S. Hanbury.
2081. L. Vidie.
2090. F. Fowke
2382. A. V. Newton.
2424. J. Drummond.
2456. P. A. Mawdsley.
2457. P. A. Mawdsley.
2667. R. H. Hess.
2862. J. Wade.
2878. T. Moss.
21. G. T. Bousfield.
94. J. Hands.

Sealed March 15, 1859.

2091. E. Smyth.
2093. W. G. Taylor.
2099. C. F. Vasserot.
2102. C. Hadley.
2105. J. Luis.
2115. E. Riepe.
2121. J. Bethell.
2127. J. Hope.
2139. T. C. Hinde.
2147. R. Bodmer.
2151. G. L. Turney.
2157. W. Clark.
2241. W. A. Munn.
2479. R. E. Pinhey and J. Wood.
2613. G. Howe and J. Norton.
2791. G. Snell.
53. E. Heywood.
93. J. Thompson.
207. C. Sharps.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

586. J. Davy and J. Milnes.
592. J. Fowler, jun.
598. E. A. Pontifex.
612. T. Porter.
618. P. Marcus.
619. W. Yates.
622. C. Coates.
625. E. T. Wright.
632. J. Pegg.
635. C. B. Normand.
762. C. B. Normand.
846. W. H. Gauntlett.
897. W. Smith.

LIST OF SPECIFICATIONS, &c.

Published during the week ending March 11, 1859.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 3s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 1649, 1660, 1669, 1698, 1699, 1737.
Boilers and their Furnaces, 1645, 1656, 1665, 1667, 1671, 1689
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1629, 1631.
Ships and Boats, including their fittings, 1646, 1651, 1674, 1690.
Cultivation of the Soil, including agricultural and horticultural implements and machines, 1626.
Food and Beverages, including apparatus for preparing food for men and animals, 1641, 1661, 1673, 1695.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1628, 1632, 1642, 1643, 1658, 1662, 1677, 1679, 1681, 1696.
Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c. *None.*
Lighting, Heating, and Ventilating, 1650, 1675.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1630, 1636, 1666, 1672, 1676, 1686, 1691, 1693.
Metals, including apparatus for their manufacture, 1635, 1637.
Chemistry and Photography, 1657.
Electrical Apparatus, 1663, 1687.
Warfare, 1634, 1655.
Letter Press Printing &c. *None.*
Miscellaneous, 1627, 1633, 1638, 1639, 1640, 1644, 1647, 1648, 1652, 1653, 1654, 1659, 1664, 1665, 1668, 1669, 1670, 1674, 1678, 1680, 1682, 1683, 1684, 1685, 1688, 1690, 1692, 1694.

1626. W. Tasker, Jun. *Improvements in combined thrashing machines.* Dated July 19, 1858.

This relates to the cleaning of the grain, and consists in fixing a riddle near the top of the caving board for facilitating the separation of the grain from the husks. The grain, after passing through this riddle and through the caving board, enters a set of riddles, fixed immediately

Digitized by Google

under, and attached to the caving board, beneath which riddles a blower is fixed, and so constructed as to direct a blast of air through the grain as it falls. *Patent completed.*

1627. T. F. CHORLEY. *Improvements in the form of bankers' cheques and other similar documents, with the view of preventing fraudulent dealings therewith.* Dated July 19, 1858.

This consists in engraving banker's cheques, &c., with certain appropriate words, which, upon the words being allowed to stand, or upon their being cancelled or torn off, the cheque will either be paid to bearer or through a bank as the case may be. *Patent abandoned.*

1628. W. HERAPATH. *An improvement in the manufacture and treatment of paper with the view to the prevention of forgery.* Dated July 19, 1858.

This consists in treating paper with a solution of Ferrocyanide, a Ferridcyanide, or a sulphocyanide of potassium, sodium, or ammonium; these salts with the alum used with size produce a tint which may be varied by the addition of small quantities of such metallic salts as will produce the required tint. The colour of common ink written upon paper prepared as above will, upon being exposed to the action of acids of an electro-negative character, be changed from black to blue or red; and with alkalies or electro-positives to a brown red, and render the attempt to extract the ink visible. *Patent completed.*

1629. C. LAMBERT. *Improvements in collars for horses and other draught animals.* Dated July 19, 1858.

This invention was described and illustrated at page 92, No. 6, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1630. S. MAW. *An improved feeder for administering food.* Dated July 19, 1858.

This feeder is so constructed that air cannot be drawn into the mouth while feeding. *Patent completed.*

1631. J. SCHMITT. *Cementing, hardening, and tempering rails for railways, and also axles for railway carriage wheels.* Dated July 20, 1858.

This consists in subjecting the rails and axles to the action of the following composition—viz., charcoal, grease, hoof-parings, tartar, coarse sugar, rosin, saltpetre, and sand. *Patent abandoned.*

1632. J. CHADWICK. *Improvements in the application of certain woven fabrics to printing purposes.* Dated July 20, 1858.

The patentee takes woollen bunting, and, by dissolved caoutchouc, &c., attaches two or more folds together, and makes a waterproof fabric termed "back-cloths," suitable for printing purposes. *Patent completed.*

1633. J. SHAND. *Improvements in fire-engines and pumps.* Dated July 20, 1858.

This invention was described and illustrated at page 124, No. 8, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1634. T. BAILEY. *Improvements in repeating fire-arms.* Dated July 20, 1858.

This consists, 1, in constructing the arms so that all the working and actuating movements are contained inside the body thereof. 2. In constructing the revolving chamber solid, or without a hole through it for a spindle. 3. In connecting the barrel to the body of the arm by a circular hook joint. 4. In certain arrangement of the parts of the lock, by which the hammer may be cocked either by the hand or by the trigger. 5. In cocking and discharging in the manner of an ordinary fowling piece. 6. In stopping the revolving chamber by a spring stop acting on the ratchet at right angles thereto, and being moved into its required positions by a cam or projection on the tumbler. 7. In cutting a notch or cavity in the cap guard or "cock nose," so that it may rest on the solid part of the chamber and retain the latter in a safe position. 8. In forming a toothed rack on the loader and the toothed segment, or small toothed wheel connected to the end of the lever, for loading the chamber. Our space will not admit of a detailed description. *Patent completed.*

1635. J. C. HILL. *Improvements in making joints for connecting pipes and other articles by means of lead or other soft metal.* Dated July 20, 1858.

This consists in inserting the two ends of pipe to be joined in a leaden collar, and compressing the same by a suitable tool. *Patent completed.*

1636. R. CLARKE. *Improvements in windows, window blinds, and shutters.* Dated July 20, 1858.

This consists in the application of springs of steel for supporting window blinds or shutters in various positions. *Patent completed.*

1637. C. DOLEY, E. BIGLAND, and T. H. WORRALL. *Improvements in ornamenting metallic and non-metallic surfaces.* Dated July 20, 1858.

This consists in ornamenting the said surfaces by designs etched upon glass plates, or by transfers obtained by printing from the said etched glass plates. *Patent completed.*

1638. G. WHEATLEY. *An improvement in the ornamenting of sticks.* Dated July 20, 1858.

This consists in ornamenting sticks by applying to them white varnish holding bronze powder. *Patent abandoned.*

1639. R. A. BROOMAN. *Improvements in movable apparatuses for receiving fecal and sewage matters.* (A communication.) Dated July 20, 1858.

This consists in providing vessels for the reception of sewage, &c., from which the liquid is allowed to flow away while the solid portions remain. *Patent abandoned.*

1640. W. N. NICHOLSON. *Improvements in crushing mills.* Dated July 20, 1858.

This consists, 1, in driving the moveable roller of crushing mills by a pinion working in cogs on the internal edge of an annular wheel mounted on the axle of the roller. 2, in supporting the bush of the moveable roller in a slot of such form that the roller as it moves may describe an arc of a circle about the centre of the driving pinion. For varying the distance between the rollers, the patentee uses an iron slide on which the bush of the moveable roller is fixed, with a circular hole to receive a flanged eccentric, and in holding the eccentric in the required position he uses a notched disc, into the notches of which a catch drops. *Patent completed.*

1641. J. V. N. S. PETRZIWALSKY. *Improvements in the manufacture of bread, and in apparatus to be employed therein.* Dated July 20, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE. *Patent completed.*

1642. W. and J. ASQUITH. *Ornamenting the surfaces of raised piled fabrics, and the apparatus employed therein.* Dated July 20, 1858.

This consists in placing at the back of the fabric one or more plain surface rollers, so that by the action of rollers set with figures or devices, which revolve upon the surface of the cloth, and to which a lateral reciprocating movement is given by a cam action, the design may be produced by changing the direction of the pile in those parts of the fabric acted upon as aforesaid, a horizontal motion being communicated to the cloth until the entire length has been operated upon, so that the pile being presented to the light in different positions may cause a difference of shade to appear, the said rollers at the back of the fabric either revolving in fixed bearings or working with a rising and lowering motion to suit the requisite pattern, which is subsequently fixed on the fabric by steaming or boiling, drying, cutting, and pressing. *Patent abandoned.*

1643. E. HARDON. *An improved manufacture of woven fabrics for covering umbrellas and parasols.* Dated July 21, 1858.

This consists in covering umbrellas, &c., with a fabric composed of cotton and spun silk. *Patent completed.*

1644. J. W. WILSON. *Certain improvements in machinery or apparatus for turning and cutting wood and other substances.* Dated July 21, 1858.

This relates particularly to the turning of wood "bobbins." The apparatus consists in arranging a series of turning lathes in a circular framing, each one consisting in a driving and following headstock, the power being communicated to the series from a main driving shaft to the driving spindles by an endless strap encircling the peripheries of their driving pulleys, and the tools for turning each article are also mounted in rests in a similarly-shaped framing, the whole system being mounted upon one rotating shaft, so as to impart to each lathe two motions, one round its own axis, and the series round the central shaft. *Patent completed.*

1645. M. MATLEY. *Improvements applicable to steam boilers for consuming smoke and economizing fuel in the generation of steam.* Dated July 21, 1858.

This consists in placing a partition at the firing end of the furnace above the dead plate, so as to form a space between the partition and the bottom of the boiler or top of the internal fire-place, this partition having in it a number of perforations so that air admitted to the cavity from the ash-place will become heated on entering the cavity, and will then pass through perforations and mix with the combustible gases. The openings at the ash-place through which the air is admitted have valves or dampers by which the passage of the air may be regulated or shut off. The arrangement above described is used in combination with a hollow "fire-bridge" supplied with air from the ash-place, which is allowed to pass from the fire-bridge through perforations made in the back of it. *Patent completed.*

1646. T. PIATTI. *An improved propeller.* Dated July 21, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1647. L. CUNQ. *Improvement in calculating machines.* Dated July 21, 1858.

This relates to the well-known caculating rule, and has more particularly in view the application of the instrument to the rapid calculation of the quantity of liquid running in a certain length of time through an orifice of given diameter under a given pressure. The instrument is based on the same construction as the straight logarithmic calculating rule, but with its divisions instead of straight lines on four concentric circles, one of which is fixed and the three others moveable round the first one, the fixed circle and two of the other ones being divided so as to have the same intervals corresponding with the same central angles, and to have these divisions in logarithmic proportions with the length of the periphery, the scales of the two just mentioned moveable circles being further divided in opposite directions to the scale of the fixed circle. The periphery of the third moveable circle is provided with two scales following each other, the unit being the half of the periphery. *Patent abandoned.*

1648. H. ALLNUTT. *A vehicle for lamplighters.* Dated July 21, 1858.

This consists of a stage, mounted at such a height on a carriage travelling-frame or support that a person placed on it may easily reach the lamps. The frame is carried on wheels, and provided with draught arrangements for horse traction. *Patent abandoned.*

1649. J. W. GILES. *Improvements in locomotive or traction engines.* Dated July 21, 1858.

This relates to engines propelled by jointed levers, attached at one end to the engine, and furnished at the other end with feet which descend on to the land, and the propelling action obtained by straightening out the lever by the power of the engine. This invention consists in attaching the jointed levers to the engine at a point near its centre of gravity, so that the whole or nearly the whole weight of the engine is applied to resist the upward pressure of the propellers. *Patent completed.*

1650. J. MEACOCK. *Improvements in wet gas meters.* Dated July 21, 1858.

This consists in fitting a tube to the valve-box in wet meters which leads directly into the spout from whence the gas enters the drum and wheel of the meter; in fitting the float at the back of the drum, and in attaching a double valve or stop to the spindle of the float, or to a spindle connected by a lever or levers to the float. Upon attempt being made to tamper with the meter, by tilting it upwards or downwards, the float would either rise or fall, and stop the outlet pipe by bringing one or other of the valves or stops into action. *Patent abandoned.*

1651. D. W. WARDER. *Improvements in the manufacture of beams, girders, ships' ribs or frames, and other structures of wrought iron.* Dated July 22, 1858.

The patentee constructs or builds up his beam or girder, &c., in two or more pieces, each part being rolled of the form required. He then temporarily binds the several parts together, and unites them one to the other by welding them in the direction of their length, forming a beam the same as if produced from the rolls. *Patent completed.*

1652. B. BLAKE. *An improved kiln for burning earthenware, and other similar articles.* Dated July 22, 1858.

Here the fire-places are arranged at certain intervals all along the outside walls of the kiln; the fire-places are each to be provided with a narrow passage or "goit." Each "goit" communicates with "bugs" or flues, with holes or openings for distributing the heat regularly throughout the kiln and flue within the kiln, to prevent the flame "flashing" upon the ware. It also consists in the use of a series of arched shelves, made of fire-clay bars, quarries, or tiles, and fitted up throughout the entire length of the kiln one above another, and placed against the two opposite "bugs" or flues. These shelves are to receive the earthenware to be burnt. *Patent completed.*

1653. H. GREEN. *A new or improved hinge for hanging and closing doors, grates, or windows.* Dated July 22, 1858.

This consists of a hinge in which the mechanism for hanging and closing the door, gate, or window is acted upon by a weight. Its details are not described apart from the drawings. *Patent completed.*

1654. C. GAMMON. *Improvements in the fastening of envelopes and letters.* Dated July 22, 1858.

Here a small metal catch is attached to the envelope. *Patent completed.*

1655. W. L. THOMAS. *Improvements in ordnance, fire-arms, and apparatus generally in which gunpowder is employed.* Dated July 22, 1858.

This consists in constructing ordnance, fire-arms, &c., according to the impulsive force or action of impact which the gunpowder exerts on the shot, &c., and also according to the fact that the initial force of relative quantities of powder exerted on the shot, the charges being of the same form, increases in a much greater ratio than the quantity. The metal material of the gun has to be distributed accordingly; the precise forms and dimensions to be adopted of course varying, but the gun or piece is made thick about the breech. *Patent completed.*

1656. J. P. B. A. THIERRY, Jun. *Improvements in furnaces.* Dated July 22, 1858.

This relates to a previous patent of the patentee, and consists, 1, in mixing atmospheric air with the superheated steam before it passes into the furnace; 2, in superheating the steam before introducing it into the furnace by passing it through hollow fire-bars. *Patent completed.*

1657. A. B. TRIPLER. *Improvements in obtaining products from a species of asphaltum at present found in the Island of Cuba, and called chapafote.* Dated July 22, 1858.

The matter above mentioned is heated in a still, and the vapours which rise from it are condensed. The products consist of oily, fatty, bituminous, and other substances, which may afterwards be separated. *Patent completed.*

1658. H. HIGGINS, and T. S. WHITWORTH. *Improvements in machinery for spinning and doubling or twining cotton and other fibrous materials.* Dated July 22, 1858.

The patentees claim, 1, the use of jointed rods or levers for putting up the carriage or creel, and working in concert with a quadrant or other part of the mule. Also, the use of the scroll or spiral pinion, (as described,) for giving motion to a quadrant wheel or rack. 2, the use of eccentric or equivalent apparatus in place of the usual scroll, the essential feature of this part of the invention being the use of a band which continues to act at the same angle to the shaft. 3, driving the change or cam-shaft by a friction surface mounted on the boss of the backing-off-wheel. 4, the adaptation to the small pulley or disc for acting upon the fallers of a part acting as a stop, but capable of allowing more than one revolution if required. 5, the method of attaching or coupling parts of the mules. *Patent completed.*

1659. L. J. MARKS. *Improvements in compasses.* Dated July 23, 1858.

The patentee applies to the card, in addition to the ordinary needle, several magnets, by preference radiating from the axis of the card, and at equal distances from each other. *Patent completed.*

1660. W. A. GILBEE. *An improved rotary engine.* (A communication.) Dated July 23, 1858.

This engine is composed of two cylinders united end to end, and attached together by a common plate which serves as a separation, and having one shaft passing through them, provided in each cylinder with a cast iron piece or washer, which latter also supports two wings or pistons. These pistons move in a circular direction in an annular space divided into two equal parts by moveable partition plates. The steam enters at both ends of the cylinder through ingress pipes, and passing through the valve chest and orifices, presses simultaneously against the two pistons, and causes them to travel over a half circumference. At this moment the partition plates, which slide in grooves, rise, and allow the pistons to continue their course. To facilitate the passage of this dead point the pistons of the second cylinder are disposed perpendicularly, in such wise as to be at their highest point of power. A perfect vacuum is kept up in front of the pistons by the part of the cylinders through which they have to pass being in constant communication with the condenser. *Patent abandoned.*

1661. R. P. WALKER. *Improvements in machinery for hulling and finishing rice and similar grains.* Dated July 23, 1858.

Here the patentee passes a thin flat stream of rice into a cylinder covered with emery, and causes the same to pass beneath elastic rollers whose surfaces travel at a slightly different speed to the main cylinder, to cause a rolling and rubbing motion between the cylinder and its rollers, and to

Digitized by Google

the said rollers he imparts simultaneously an endways motion, which slips the hull endways off the rice, thereby ensuing a proper hulling, and with very little waste from broken berries. *Patent completed.*

1662. H. BARBER. *Improved machinery for producing knitted fabrics.* Dated July 23, 1858.

The object here is, 1, to simplify the mode of selecting moveable presser bits which are used to press down the beards of the needles employed in the ordinary stocking frame or loom. It next relates to the use of a bar or bars for holding in position the presser bits after they have been selected. Next to the use of a peg cylinder for acting on the levers, whereby the position of the presser bits may be changed, so as to produce the pattern or knitted fabrics. The needle is made with a sliding or moveable presser for closing the beard when required. The invention is not described apart from the drawings. *Patent completed.*

1663. G. BROKELBANK. *Improvements in laying submarine cables for telegraphic purposes.* Dated July 23, 1858.

The telegrabhic cable, as it is payed out from the ship, is passed down a sustaining cable which is attached to the stern of this ship, and is itself supported at one or several points in its length by ropes. *Patent abandoned.*

1664. W. PARSONS. *Improvements in separating the solid matter from sewage waters.* Dated July 23, 1858.

Here the sewage is raised by pumps to such a height as to obtain a considerable head, and from this elevation is conducted by pipes into bags of woven fabric, which are protected by cases of perforated metal to enable them to sustain the pressure. The fluid parts of the sewage pass through the bags, and the solid parts are retained by them. *Patent abandoned.*

1665. H. J. GIFFARD. *Improvements in feed apparatus for steam and other boilers, which improvements are also applicable to the raising and forcing of fluids.* Dated July 23, 1858.

Here the impulsive force of a steam jet or blast is made to raise and force the fluid required. This apparatus consists, according to one arrangement as applied to a steam boiler of a steam jet or injection pipe, which receives the steam from the boiler, and directs it in a continuous jet into a small passage the lower end or mouth of which is expanded sufficiently to admit of the entrance of a stream of water, which, by surrounding the steam jet pipe, forms an annular jet of water with the steam jet in the centre. The water is drawn from a well or tank in any convenient situation. *Patent completed.*

1666. C. ATKINSON. *A certain improvement in Venetian blinds.* Dated July 24, 1858.

This consists in the use of thin strips of steel, for mounting the laths in the construction of venetian blinds, the vertical strips being hinged to admit of their folding up. The blind may be used also as a shutter. *Patent abandoned.*

1667. M. SHANTY. *A mercurial level, to show the height of liquids in enclosed and opaque vessels, vases, and principally for steam boilers.* (A communication.) Dated July 24, 1858.

A complete specification of this invention was filed with the application, and it is not described apart from the drawings. *Patent abandoned.*

1668. W. MERRY. *Improvements in apparatus for preventing the escape of foul air from area, kitchen, and scullery drains of dwelling-houses, also from street, stable, and slaughter-house drains.* Dated July 24, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1669. M. SHANTY. *A metallic trimming for intercepting water, air, gas, or steam round piston rods, of whatsoever they may be; the same may be applied to the joints of steam machines.* (A communication.) Dated July 24, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE. *Patent abandoned.*

1670. S. TOWNEND. *Improvements in cranes.* Dated July 24, 1858.

The object here is the application of a self-adjusting counterweight capable of adapting itself to, and thereby balancing different weights to be lifted. *Patent abandoned.*

1671. J. F. BELLEVILLE. *An improved smoke-consuming apparatus or furnace.* Dated July 24, 1858

This consists of two sets of fire-bars, one large set composed of louvre-like bars arranged so that their edges all lie in a plane inclined at an angle of about 45 deg., with a space for the admission of air between every two bars; the other and smaller set is placed horizontally at the bottom of the inclined louvre bars. The large set of bars consists of metal laths arranged stepwise over each other so as to form a plane sufficiently inclined to allow of the fuel employed falling by gravitation. A feed hopper is fixed over the inclined grating. Flues are made in the brickwork of the apparatus for the admission through regulating valves of air, which becomes heated in its passage, and is admitted through the openings between the louvre bars and into the upper part of the apparatus. Between the bottom of the louvre bars or grating and the horizontal bars, there is a door through which clinkers may be removed. *Patent completed.*

1672. H. C. TRAPHAGEN. *Improvements in ladies' skirts.* Dated July 24, 1858.

This consists in attaching to a skirt a series of air-tight tubes, placed horizontally on the skirt to be inflated with air. *Patent abandoned.*

1673. H. WIKOFF. *An improved aperient medicine, to be used in the shape of a biscuit, cake, or sweetmeat.* (A communication.) Dated July 24, 1858.

This consists in mixing "Arabian scammony" with cakes, biscuits, &c. *Patent abandoned.*

1674. D. ADAMSON. *Improvements in hydraulic apparatus for raising and lowering heavy articles, and in the application of hydraulic power for riveting metallic structures, as iron ships' boilers, tanks, and similar articles.* Dated July 26, 1858.

This consists, 1, in improvements in the construction of hydraulic lifting jacks. 2, in the application of a separate valve, called a pass valve, for the passage of the fluid from cylinder into the ram cistern when it is requisite to lower the head of the ram or the weight. 3. in the mode of acting on the pass valve when the ram has to be lowered. 4, in the application of hydraulic power for riveting metallic structures, such as ships' boilers, tanks, and similar articles. 5, in certain improved modes of constructing hydraulic apparatus for riveting. These several improvements are not described apart from the drawings. *Patent completed.*

1675. C. F. VASSEROT. *Improvements in glass roofs, skylights, and other glass structures.* (A communication.) Dated July 26, 1858.

This consists in joining together the panes or sheets of glass by a flexible band, the joint being either air-tight, or made to receive and convey outside the condensed moisture from the insides. *Patent completed.*

1676. A. SAX. *Improvements in wind musical instruments.* Dated July 26, 1858.

The patentee claims constructing brass and musical instruments in which pistons are made use of in such manner as to allow of giving, with musical exactness, all the notes of their chromatic scale, by providing the said class of musical instruments, besides the descending pistons, with descending ones, for giving the ascending chromatic notes. *Patent completed.*

1677. J. COOKE. *Improvements in singeing, treating, or finishing textile fabrics.* Dated July 26, 1858.

Under one form of the machinery used the fabric to be singed or heated is passed from a horizontal beam round guide rollers, and thence over or in contact with a fixed bush or scrubber, which raises the loose fibres and renders the surface better suited for being singed; and from this point it passes over a row of gas flames, by which the piece is singed upon its upper surface, a stream of heated air being passed upon the row of gas flame at the point of contact with the fabric. After quitting this point the fabric passes inside angle iron, and thence over a trough containing cold water, which, together with the row of gas flame, is covered by an exhausting chamber connected with an exhausting fan. The piece then passes beneath a bush roller or scrubber, and over or through a second singeing arrangement of a kind similar to that just described, and it then traverses between a pair of nipping rollers which act as dampers in putting out any sparks left on the surface. The fabric finally passes round a guide roller and is then beamed upon a roller in a finished condition. *Patent completed.*

1678. J. HARDIE. *Improvements in apparatus for regulating the flow or passage of fluids.* Dated July 26, 1858.

This relates to valvular apparatus for use in different situations where the flow or passing of fluids is to be regulated, and particularly in water-closets where a predetermined supply of cleansing water is to be periodically let on. There are several modifications included, which we cannot give in detail. *Patent completed.*

1679. J. TAYLOR and J. NIMMO. *Improvements in healds, and in machinery or apparatus for making healds.* Dated July 26, 1858.

This relates to Bernie and Anderson's patent, dated 25th March, 1835. In the improved healds the counts or sets are marked by the introduction into each leaf of a determined number of legs, loops, or stitches, of coloured threads. These threads are worked in by the marker, who, according to one modification, on arriving at the part of the leaf where the marking is to be made, detaches the usual pirn and attaches the pirn of coloured yarn, working it into the upper half of the heald until the proper number of marking legs or eyes are worked in, when the ordinary yarn is resumed. *Patent completed.*

1680. B. T. HARRIS. *Improvements in registers for indicating the presence or absence, and the time of arrival and departure, of workmen or employés.* Dated July 26, 1858.

The inventor makes use of a registering surface of paper, moved by clockwork, and in connection to this he uses a row of pins standing at right angles to the line of motion of the registering surface. Each workman has one of these pins assigned him, and each time he comes to work he operates the said pin to make a mark on the registering surface, and he also makes a similar mark on leaving work; hence the space between each alternate pair of marks indicates the time the workmen has been employed. He also makes use of a perforated plate or its eqivalent, behind which black and white or dissimilar surfaces or devices are alternately exposed to view, to indicate the presence or absence of the workmen by inspection. *Patent abandoned.*

1681. C. DE JONGH. *An improved system of, and machinery for heckling or combing flax, silk, or other fibrous substances.* Dated July 26, 1858.

This relates to heckling and combing machinery whereby stricks of flax, silk, &c., may be submitted to the action of different gradations of pins in succession, each gradation commencing to operate at the end of the strick, and working up to the holder without the aid of a moveable head trough for carrying the holders. *Patent completed.*

1682. T. HALL. *Improved apparatus for indicating a rise of temperature in confined spaces.* Dated July 26, 1858.

The inventor employs an air-tube, or a system of air-tubes, closed at one end and connected at their open end to a tube in direct communication with a mercurial or fluid indicator. *Patent abandoned.*

1683. E. JONES. *Effecting a better system of drainage, and the machinery or apparatus necessary for the same, whereby the sewage manure is collected and conveniently exported for use, and the noxious effluvia prevented from contaminating the air of populous cities and towns, and whereby the drains may be more strongly and securely built, by the manufacture of a more suitable and better material.* Dated July 26, 1858.

This invention is not described apart from the drawings. The patentee claims, 1, portable tanks for collecting the sewage and débris of the streets, together with filtering gratings and flood-gates (as described), with the mode of effecting their removal; 2, gully traps and tanks as described; 3, the closet pan and traps with the flexible joint and apparatus as described; 4, the sink and area trap and tank; 5, the mode of manufacturing bricks (as described) by the combination of pistons, levers, and perforators connected with the cutting apparatus for preparing the blocks. *Patent completed.*

1684. H. JACKSON. *Improvements in preparing lubricating matters.* Dated July 26, 1858.

Here the tallow is broken into small pieces and placed in a vessel, which is then closed, and the air is exhausted. Afterwards connection is made between the vessel and a retort in which oxygen is generated; when the oxygen in the vessel has arrived at a considerable pressure, it is allowed to escape by a weighted valve. The tallow when it has been kept in contact with oxygen under pressure for some time, is removed from the vessel, and ground with an amalgam of mercury and tin. *Patent completed.*

1685. J. HOPE. *A new and useful mechanism or apparatus for supporting and adjusting a graver of a machine, for engraving the surface of a calico printer's roller, preparatory to the same being etched.* Dated July 26, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1686. J. DAVIES. *Improvements in cloaks for military and other purposes.* Dated July 26, 1858.

This consists in constructing them so that each cloak may also serve as a tent. *Patent abandoned.*

1687. P. A. GODEFROY. *Improvements in the cleansing of gutta percha, and in the more perfect insulation of electric telegraph wires.*

This invention is not described apart from the drawings. *Patent completed.*

1688. H. GLOVER. *Improvements in instruments for measuring angles and taking altitudes.* Dated July 26, 1858.

The object here is to measure the angular distance of two or more objects from each other. The inventor can measure not only the angular distance of two distant objects, but their altitude also. He can also obtain the zenith distance of an object without a sea or artificial horizon. The instrument consists of two graduated arches, combined so that the plane of one arch shall be at a right angle to that of the other. Each arch has a limb attached with a nonius, as usual in sextants, and has also reflectors placed on the end, through which the axis pin is placed. One of these arches measures the altitude, and the other the angular distance between two contiguous objects that are at the same altitude. The arch measuring the distance apart lies horizontally, and that which measures altitude is vertical when held in position for conducting observations. The invention is not fully described apart from the drawings. *Patent abandoned.*

1689. H. ASHTON. *Improvements in the furnaces of steam boilers.* Dated July 26, 1858.

In applying this invention to the fire-box of a locomotive steam engine, the inventor makes the door in two halves, hinged together, and to the door frame attaches a slanting plate by which the air is guided on to the fire. An adjustable plate may be applied to this slanting plate to guide the air closer to or further from the fire. He makes the door frame capable of being easily removed from the fire-box, so that the tubes may be got at with facility. *Patent abandoned.*

1690. J. SCOTT. *Improvements in pumps, which improvements are also applicable for the propulsion of ships, vessels and boats.* Dated July 27, 1858.

This relates to the pumping or forcing of liquids by a rotary helical coil of piping or tubes. *Patent completed.*

1691. J. EMES. *A portable folding bedstead.* Dated July 27, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1692. T. LINE. *Improvements in engines for raising beer and other liquids.* Dated July 27, 1858.

This relates to a former patent granted to H. James, 16th May, 1857. The inventor mounts a plate or disc carrying an arm or hand lever, arranged on the top of the pump cylinder, and that cylinder is at its lower end attached to a shop counter or other suitable support. Thus, in this arrangement, it is the pump cylinder alone which carries the plate or disc and the arm or hand lever. *Patent completed.*

1693. A. TAYLOR. *Improvements in pianofortes.* Dated July 27, 1858.

The patentee introduces glass into certain parts of the piano. *Patent completed.*

1694. C. N. KOTTULA. *Improvements in the manufacture of soap.* Dated July 27, 1858.

This consists in combining "fitted" soaps with "neutral hydrated" soaps, or the elements of such neutral soaps, that is to say, with soaps made of cocoa-nut oil, or tallow, or certain other descriptions of fatty matters and soda leys, without separation of water or leys. *Patent completed.*

1695. J. LONG. *Improvements in cooling brewers' and distillers' worts and other liquids.* Dated July 27, 1858.

This consists in placing within the vessel in which the worts, &c., are to be cooled two longitudinal battens covered by canvas, cloth, &c., the said battens stopping short of the ends of the vessel, and in blowing air in upon the worts or other liquids below the cover, so that the worts, &c., shall be caused by the blast to flow between the battens towards the end of the containing vessel, and passing round the ends of the battens return outside of them, again entering between them to undergo the cooling action of the blast. *Patent abandoned.*

1696. G. HURN. *Improvements in the manufacture of certain articles made from fibrous materials.* Dated July 28, 1858.

A complete specification of this invention was filed with the application, and an abridgment of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MARCH 25, 1859.

THE NEW PATENT OFFICE BUILDING.

ABOUT £9,000 a-year is what Her Majesty's two law officers, the Solicitor-General and Attorney-General, divide between them from the fees on patents. £4,500 per annum, easily earned, ought to be sufficient, one would think, to keep each of these gentlemen a little true to the interests of patentees; and yet we have to charge them with lending themselves to a movement which ought to be discountenanced by them to the utmost.

It is tolerably well known by this time that a splendid library lies awaiting exhumation in the "dark arches" of the present Great Seal Patent Office, and also that covetous hands are endeavouring to drag library, museum, and offices all westward. "To South Kensington with them!" was the first cry; and now that this has become hopeless of success, "To Burlington-house!" is the new note of certain gentlemen who have already more to do with the Patent Office than is desirable. Now, it is to the Commissioners of Patents, and especially to Sir Fitzroy Kelly and Sir Hugh Cairns, that we have looked for an official resistance to these cries. That the removal of the office and library to Piccadilly would be a highly improper thing, must be very evident to all who think for a moment on the subject. The persons who visit them daily and hourly are inventors, patentees, patent agents, and lawyers. The first three classes have, as a matter of course, perpetually recurring occasions of attending both the office and the library; and as to barristers and solicitors, there are now no less than 3,000 registered deeds in the office, in which these gentlemen almost exclusively are concerned. Now, do inventors, patentees, patent agents, barristers, and solicitors, congregate at Chancery-lane, where the Patent Office and Library now are, or at Piccadilly? Further, it is well known that a concentration of all the law courts and offices, with which the Patent Office is most intimately concerned, is extremely likely to take place on ground adjoining Chancery-lane. Sir Richard Bethell, for one, has set his heart upon the accomplishment of this, and with the Suitor's Fund of unclaimed millions to draw upon, he will doubtless attain his end. With what reason, then, can the permanent removal of the Patent Office and Library to Piccadilly be contemplated?

That the Commissioners of Patents thoroughly understand the matter is very evident, for only a very few weeks since they represented the facts of the case to the Lords of the Treasury in a memorial which is now before us. From it we extract the following sentences:—

"The 4th section of the said Act enacts, that 'it 'shall be lawful for the Commissioners of Her 'Majesty's Treasury to provide and appoint from time 'to time proper places or buildings for an office or 'offices for the purposes of the said Act.' In pursuance of the requisition of the Lords Commissioners of Her Majesty's Treasury, dated in 1853, the Commissioners of Her Majesty's Board of Works provided certain offices for the Commissioners of Patents, being the ground-floor rooms of the Masters' offices in Southampton Buildings, Chancery Lane, theretofore occupied by Masters in Chancery, abolished under the Act 15 and 16 Vict. c. 80.; and an annual rent of £490 is now paid out of the Fee Fund of the Patent Office to the Suitors' Fund of the Court of Chancery for the hire of the same. This arrangement was not considered to be permanent; no lease has been granted, and as these offices are now required for the occupation of the registrars and other officers of the Court of Chancery, the notice has been given to the Commissioners of Patents, requiring them to give up possession so soon as other suitable offices can be procured. These offices were, in 1853, sufficient in number and accommodation for the ordinary business of the office. In the year 1855, the Commissioners of Patents established a free public library within their office, containing works of science in all languages, the publications of the Commissioners, and the works upon patented and other inventions published in the British Colonies and in Foreign countries. This library has greatly increased and continues to increase, partly by purchases, but in a great measure by gifts and loans of valuable and useful books. It was resorted to at the first opening by inventors, engineers, and mechanics, as well as by barristers, solicitors, and agents engaged in Patent business; it has become a collection of great interest and importance, and the number of readers has gradually so much increased that at this time convenient standing room cannot be found in the two small rooms within the office which can be appropriated to the library. It is the only library within the United Kingdom in which the public have access, not only to the Records of the Patents and Inventions of this country, but also to official and other documents relating to Inventions in Foreign countries, and this without payment of any fee. A largely-increased accommodation is urgently required. No suitable building can be found in the immediate neighbourhood of Southampton Buildings, either to be rented or for purchase. The new offices to be provided must be fire-proof, for the preservation of the original Specifications and other Records of the office; the offices now occupied are fire-proof throughout. The Commissioners of Patents are in possession of a collection of very valuable and interesting models of patented machines and implements, as also of portraits of inventors, many of them gifts, and others lent by the owners for exhibition. They are now exhibited daily, and gratuitously, in a portion of the Museum at Kensington assigned to the Commissioners of Patents for that purpose by the Lords of the Committee of Privy Council for Trade. A museum of this nature necessarily increases, and the number of models now exhibited may be considered as forming only the foundation of a great national museum..... They are of opinion that the surplus income, calculated as before stated, to amount to £30,000 at the end of the current year, 1859, and to increase in each succeeding year at the rate of £20,000 per annum, may be beneficially applied in the purchase of ground in a central situation, and in the erection thereon of a sufficiently spacious fireproof building for the Patent Offices and public free library attached thereto; and that the surplus fund may also be beneficially applied in the purchase of ground and the erection thereon of a permanent and spacious building for the Patent Office Museum, sufficient ground being taken for the extension of the building, from time to time, as may be required. This is the more necessary inasmuch as models of the most interesting and valuable description lie scattered over the kingdom, in many instances constructed at a great expense, for legal and other purposes, for which the owners have no present use, and many of which occupy a space inconvenient to them. These models, or many of them, would, as the Commissioners confidently expect and believe, be presented or intrusted to them for exhibition in such museum, provided the public are allowed free access to it at all reasonable times. *The Patent Office is the place of constant, daily, and hourly resort of patentees, agents, and all others concerned in obtaining patents, and in ascertaining what discoveries and improvements have already been made. It should be conveniently placed with reference to the courts of law, the government offices, and the offices of the attorney and solicitor-general.* With respect, however, to the proposed new museum, the Commissioners of Patents are of opinion that the same reasons for a central position do not exist, and that it might be placed upon any spot easily accessible to the inhabitants of the metropolis, and that the place in which the models are now exhibited would be an eligible position, sufficient ground being there purchased or assigned for the purpose. A large space will be required for the building in the first instance, and a larger extent must be provided for its future extension, and sufficient ground cannot be found in the centre of the town for a building of the extent required, unless at an enormous cost."

Here we have the case stated clearly and fairly enough. But, unhappily, some bad influence has very lately been brought to bear upon the learned gentlemen who signed the memorial (Lord Chelmsford, Sir John Romilly, Sir F. Kelly, and Sir H. Cairns), and they have lately, as we are informed, consented to build "the place of constant, daily, and hourly resort of patentees, agents, and all others concerned in obtaining patents"—at Piccadilly! We appeal to these gentlemen against so monstrous a repudiation of their own good sense, to say nothing of the feelings and desires of others.

We entirely deny that any insuperable obstacle prevents the acquisition of a suitable central site for a Patent Office. It is, of course, not to be expected that large plots of building ground are to be obtained in abundance in the very centre of the metropolis. We must be prepared to buy and pull down a few old buildings, before we can put up new and spacious edifices. With this understood, there need be no difficulty in securing even a choice of sites for the new Patent Office. We will point out two. In the first place, there is a large plot of ground between the new Record Office and Chancery-lane which would answer the purpose most admirably, and which might be built upon without delay. Secondly, why should not the building at present occupied by the Commissioners of Patents be purchased, and with it the block of buildings between it and Chancery-lane? These may, we confidently state, be purchased on fair and reasonable terms, and with these for their own, the Commissioners may rear a Great Seal Patent Office worthy of themselves and of this nation of inventors. Were there but the will, there would be no want of the way.

And now a word or two as to financial matters. The reader will observe that in the extract which we have quoted, the Commissioners put down the probable surplus income at the end of 1859 as £30,000. This is a most false estimate. We will explain how it has been made. In the Patent Law Amendment Act of 1852 provision was made for the payment of certain sums, part in fees and part in stamp duties. The stamp duties were £5 payable on the Law Officer's Warrant for Letters Patent; £10 out of the third year's fee of £50; and £20 out of the seventh year's fee of £100. Now, some official gentlemen or other—we know not who exactly—*chose* to put down these sums as so much "Revenue," and paid them into the Treasury as such. In 1853, however, another Act was passed converting the whole of the payments (including fees) into stamp duties, and therefore abolishing his pretended distinction between the two kinds of payments. But, strange to say, no corresponding change has been made in the manner of keeping the accounts. Every year, away goes a large sum from the surplus Patent Fund as "revenue" still. The amount thus abstracted since 1852 is nearly £90,000. The Commissioners estimate the "Revenue Stamp Duties" for the current year at £16,000 more. So that the actual surplus fund raised from patentees since 1852 is at least £100,000 more than the Commissioners represent. This sum ought—every farthing of it—to be available for the new building if required, and with it we have no need to go begging a bit of Burlington-gardens from Lord Derby.

We earnestly hope the Commissioners will consider the facts we have here stated. Who is to care for inventors if they who draw from them handsome emoluments are untrue to hem?

PATENTS FOR INSTRUMENTS AND MUNITIONS OF WAR.

PIQUED, probably, at the sarcasm which their official trifling with Sir W. Armstrong's invention has called down upon them, the Government have again determined to seek the powers necessary for the suppression of patents for instruments and munitions of war. A bill has accordingly been prepared by Mr. Attorney-

Digitized by Google

General, Mr. Solicitor-General, and General Peel, and was read a first time in the House of Commons a few evenings since. It is published in full on another page of this Magazine.

It will not be possible for the reader to comprehend the sinister and dangerous nature of this measure, without recurring to the circumstances which have led to its production. On the 18th of October, 1855, a paper, of which the following is a copy, was issued from the War Department :—

"(Copy.)

"*Patent Law Amendment Act*, 1852.

"I, Charles George Bannister, of Pall Mall, Middlesex, Solicitor for the War Department, and for and on behalf of Her Majesty's Principal Secretary of State for the War Department, hereby give notice that I object to the sealing of Letters Patent to John Macintosh, of Great Ormond Street, Middlesex, for the Invention of 'Improvements in the application of Incendiary Materials to be used in Warfare,' as set forth in the warrant of the Solicitor-General for the sealing of such Letters Patent, received and recorded in the Office of the Commissioners of Patents for Inventions, on the 18th day of December, 1855. And my objections to the sealing of such Letters Patent are as follows:—That such an invention can only be useful in time of war, and that the publication of it may be prejudicial to Her Majesty's service.

"Dated this 18th day of December, 1855.

"(Signed,) CHAS. G. BANNISTER,
"Solicitor, War Department."

Now, we have nothing whatever to say against the formal legality of this document, taken by itself, because the Act of Parliament (15 and 16 Vict. Cap. 83, cl. 12) expressly authorises "any persons having an interest in opposing the grant of letters patent" to state their objections in this manner. But what should be most carefully observed is, that by stopping the sealing of the patent in this way until the war was ended, the Government arbitrarily deprived the inventor of all right to a patent for his invention, because the Lord Chancellor had no legal power to extend the time allowed for sealing the patent beyond one month. By consulting the 6th clause of the 16th and 17th Vic. cap. 115, the reader will find it expressly stated that "it shall not be lawful for the Lord Chancellor to extend the time for the sealing of any letters patent, or for the filing of any specification, beyond the period of one month." With this fact before them, however, the month was allowed to elapse—as were other months afterwards—with the patent unsealed, and therefore destroyed. Hence sprung Mr. Macintosh's just claim for compensation. That claim was, however, cavilled over until the war ended, and the invention became for the time useless, when, in order to avoid it we presume, the Solicitor of the War Department withdrew his opposition, and the Lord Chancellor—in flat contradiction to the law laid down in the clause just quoted—affixed the Great Seal to the patent. From that time to this Mr. Macintosh has received no compensation from the Government, either for the invention itself, or by way of compensation for these arbitrary infringements of his legal rights. Next has come the case of Sir W. Armstrong's gun. Here the authorities have thought a semblance of secresy desirable, although secresy itself has been proved impossible. Very recently Sir William has applied for two further patents, and the Act now under consideration is intended to provide, doubtless, for the sealing up of the facts concerning these.

As to the Act itself, we are really unable to speak of it with any respect whatever. The first clause "enacts" that an inventor of any improvement in instruments or munitions of war *may*, "for valuable consideration or without," assign the benefit of his patent to the Secretary of State for War. That appears to us to be a very curious thing to enact. Who ever doubted that an inventor "*may*," if he please, assign his patent to General Peel or any one else? We all know very well that inventors not only *may* but *have* so assigned them. The War Department cannot possibly be ignorant of this fact, because Lord Panmure only three or four years since purchased a patent for a gun from an American gentleman, who, on his part, felt no difficulty, so far as we know, in receiving a cheque for the £10,000 paid him. Surely the mere fact of the patent being worthless could not have been the only reason why he was allowed to sell it and the Secretary of State to buy it. Perhaps, as the second clause of the new Bill is retrospective, the object of the measure is to justify this particular transaction!

The Bill does not—as we feared it might—propose to give the Government any new power of suppressing an invention without the consent of the inventor. The assignment of the invention or of the patent to the Secretary of State is to be, it appears to us, indispensable to the Government control—a circumstance which indirectly shows how unjust were the proceedings of Lord Panmure and his solicitor in respect to Mr. Macintosh's patent. But this feature of the measure by no means renders it innoxious. Let us briefly examine how it is likely to work in practice.

The inventor of an improved gun, for example, may do one of two things: he may either communicate directly with the War Department before applying for Provisional Protection under the Patent Law; or he may first apply for this Protection, and then address himself to that Department. Now, in the first case, if his invention be pronounced valuable, he will very naturally demand a high compensation for it, and will be disposed to urge this under the threat of making it public. Here, then, at the very outset, is a direct encouragement to extortion, which we are quite sure will be found to work with very bad results. On the other hand, if the War Department is disposed to be niggardly—and that is by no means an improbable case—the inventor will feel no encouragement to proceed with his plans here, but will at once carry them to some foreign Government which is known to be more liberal. The case will not be very different when the inventor obtains his protection before he applies to the Government; the difficulties described will still be experienced.

It may be thought by some that inventors will be disposed to assign their rights to the Secretary of State, leaving the amount of remuneration to be subsequently fixed. But clause 11 of the new Bill will, we think—and we know inventors pretty intimately—forbid this. That clause gives the Secretary of State, it will be observed, legal power to repeat what was done illegally with Mr. Macintosh's invention, viz., to fling the invention overboard, and with it the claims of the inventor, whenever it may suit the purpose of the Government to do so.

We have discussed this bill on its own grounds as a measure of Patent Law Amendment. Upon the more general considerations which might be adduced against it, as a matter of policy we shall not here enter. Some may think we display too little confidence in Secretaries of State and Public Departments. To simple-minded men it may seem incredible that anything but fairness and liberality is to be expected from the holders of high offices in this country. But too many of us know well the fallacy of such thoughts. Office, and especially high office, works miracles on men, and all its miracles are mischievous. It makes men of clear vision blind; men of quick hearing deaf; men of sound judgment senseless; men of pure virtue immoral. So seldom is justice done to individuals by Governments, that we pity the man, be he who he may, who has to put his trust in them. He *may* get justice done him; but if he does it will come by chance, and bring with it neither sanctity nor sweetness.

THE PRESENT STATE OF NAVAL ARCHITECTURE.

REFORMERS as we are, the Government of Lord Derby has a very considerable amount of sympathy from us, and we heartily wish them well through their trouble. Some of the prominent members of that Government are personally entitled to the respect of men of science, and we have observed, in the course of our experience, that Conservative Cabinets are more heedful of the claims of science upon their support than our late Liberal Cabinets have been. In no case is this more clearly displayed than in the relation between the Government and the science of naval architecture, and we had hoped much in this regard from our liberal-minded chief at the Admiralty.

We believe we have reached a period in our naval history of greater importance than any through which we have passed, and nothing can be more detrimental to our naval interests than perpetual changes in the administration of its affairs. Let us mark the position in which we find ourselves at the close of the first decennary of the present half-century—a period of almost unprecedented activity in naval matters. In the year 1850, the number of *screw* ships of war which received Her Majesty's commission was 4; in 1852, 17; in 1854, 34; and in 1856, 105. Last year, out of 39 ships commissioned, 33 were steam-ships, and 25 were propelled by the screw; and so completely has the screw superseded every other mode of propulsion, that there is not, at this moment, a single *paddle*-steamer or sailing-ship on the stocks of any of our royal dockyards. The San Fiorenzo, the last of her race, is no more.

This great change has taken place mainly, as will be seen, within the last ten years. What opportunities might not have been gained during this transition period for perfecting the construction of ships of war, if, in the midst of their anxiety for the present, our Administrators had thought also of the future, and had made every step with the intention of arriving at some definite conclusion as to form, engine-power, and immersion of screw! But we fear they have thought of little beside meeting vessels of a particular class in a foreign service on equal terms, or securing such a draught of water as should make the Sea of Azov navigable, or allow of carrying guns within the forts at Cronstadt. The consequence has been that, whilst our screw ships have embodied all the *recognised* principles of naval architecture, they have failed to render new ones available; and what, rightly directed, might have been a magnificent series of experiments, is now little better than an incongruous mass of badly-observed and worse-recorded facts. We need no other proof of the defectiveness of many of our ships with regard to form, power, &c., than the inequality of their relative performances. We know it would have been as difficult to point out why and in what respects a particular design would fail, as it now is to account for its failure, and for the remarkable character of the results obtained. But this is the ground of our complaint—that, seeing the uncertainty attending the subject, so little pains should have been taken to obtain knowledge. And now we are about to enter upon what promises to be a larger and more costly re-construction than that through which we have passed, and we enter upon it as com-

Digitized by Google

pletely ignorant of the best dimensions and form of ship for securing speed and steadiness as we were ten years ago.

What we desire is, that the Admiralty should not only continue to value symmetry of form and perfection of internal arrangement, but also esteem it their duty to make every experiment performed with the public money subserve the advancement of the science of naval architecture. We will not offer a single suggestion as to how this may be done, for there are no men in the world so capable of doing it as the present staff of the Surveyor of the Navy. Had he not been so fortunate as to secure such aid, we should not now have to congratulate ourselves that Russians, Austrians, Portuguese, Turks, Brazilians, and all the smaller maritime powers, build their vessels after English models, and thus proclaim their excellence. It must not be supposed that vessels of war, constructed by private builders for foreign Governments are designs of their own. They are, in nine cases out of ten, engaged to build them like a certain class of ship in the royal navy, permission being given to increase the length or the breadth enough to gratify the self-respect of the builder, but *not* sufficient to make it necessary to enter into any calculations or re-arrangements, or to make it possible for any great blunder to be committed. We do not misrepresent our private shipbuilders when we say that although some of them know perfectly well how to make a ship that will carry a good cargo, or how to secure high speed where that is the desideratum, it would be vain to look to them for help of any importance in securing the combination of qualities which would constitute the perfect man-of-war. Perhaps we could not give a better illustration of the darkness which prevails in these high places on the subject of Naval Architecture than by reproducing a statement made by Vice-Admiral Moorsom in a memorandum drawn up for the British Association in 1857, "on the want of facts respecting the performance of vessels at sea." He says, "a correspondence and negociation was carried on above twelve months between the Government and the London and North Western, and Chester and Holyhead Railway, &c., for vessels to run between Holyhead and Kingstown at the highest attainable speed without undue risk. The negociators differed in their views, from a speed made good of somewhat under 17 statute miles an hour, up to 21 miles; that difference involving sizes of vessel somewhere about as 2 to 3; of cost in outlay nearly in the same proportion, and in working expenses about as 3 to 5.... The most striking features, however, in the case is the great difference in the size and proportion of the vessels, and in the power proposed by the several authorities who were applied to, the request being that they would state their views as to the power and size of the vessel best adapted to perform 65 statute miles in 3¼ hours. The vessels differed in displacement from about 1,550 tons to 3,000; in proportion of breadth to length, from 9·37 to 11·6 per cent; in draught of water to breadth, from 30 to 40 per cent; and in nominal horse-power, from 550 to 1,600."

So wide a range as this is, as Admiral Moorsom very properly says, hardly consistent with a scientific knowledge of the size and form of ships.

We have already informed our readers of the steps which the Admiralty have taken to secure the assistance of the best private shipbuilders and others in designing a Frigate. We saw two or three of the designs which were made for this purpose, and discovered to our astonishment that although the weights to be carried were given, with the number of guns on each side, the minimum distance between them, and other important limitations, yet one of these designs was not more than 4,900 tons burthen, while another was 7,500; and while one proposed to secure the desired speed with 1,000 horses' power, another asked for 1,800.

This, then, is the position of Naval Architecture in the Royal and Merchant Services. We have said what we think the Government ought to do towards improving this gloomy state of things, and we should like to offer a word of counsel to private shipbuilders and shipwrights. They have gone on for years in ignorance of the commonest principles on which their art is based, content to copy continually vessels which would stow a good cargo and could manage to keep their legs, and never dreaming of improvement. Such men may rely upon it they will find before long that the carrying trade is slipping through their fingers and passing into other hands. They complain already of scarcity of freights and of the large number of foreign vessels engaged in our colonial trade, attributing these evils to defective navigation laws; but they have only to build faster and better ships than their rivals, and they will soon find employment as active as they can desire. But if they set their faces against all improvement, and refuse to take means to secure for the English merchant marine the position it ought to occupy, they will fail in the competition with cheaper vessels, and there will be none to pity them in their ruin.

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, MARCH 17.

HOUSE OF COMMONS.

HARBOURS OF REFUGE.

In reply to Mr. Baxter, Sir S. Northcote said the report of the commissioners had been presented only a few days before, and its importance was such that the Government could not possibly give any answer at present as to the course which they might adopt with respect to it. It was intended to take the usual vote this year for the works at Dover and Alderney.

THE BUILDING DEPARTMENT OF THE ADMIRALTY.

Sir J. Pakington gave notice with reference to the statement on the subject of the allegations made against the building department of the Admiralty by Lord C. Paget, that he would, on an early day, move that it should be referred to the consideration of a select committee. He would give due notice of the terms in which he should make that motion.

FIRE INSURANCES.

Mr. Sheridan moved for leave to introduce a bill to reduce the duty upon fire insurances.

The house divided, when the numbers were—

For the motion	102
Against it	112
Majority	—10

STATE OF THE NAVY.

Sir C. Napier moved for a copy of letters from Sir Baldwin Walker on the state of the navy, to the Admiralty or the First Lord of the Admiralty, from March, 1858, to the end of the year.

Sir J. Pakington said the documents in question were confidential papers presented to the Admiralty, and it would be neither in accordance with precedent nor beneficial to the public service to produce them.

After some discussion the House divided, when the majority against the motion was 151. The motion was therefore lost.

MERCHANT SHIPPING.

On the motion of Mr. Lindsay the select committee on this subject was nominated, as follows:—Sir G. Lewis, Lord Lovaine, Mr. Cardwell, Mr. T. Baring, Mr. Crawford, Mr. Horsfall, Lord C. Paget, Sir J. Elphinstone, Mr Fenwick, Mr. Bentinck, Mr. Wilcox, Mr. Liddell, Mr. Dalglish, Mr. F. Russell, and Mr. Lindsay; power to send for persons, papers, and records; five to be the quorum.

FRIDAY, MARCH 18.

HOUSE OF COMMONS.

DECIMAL CURRENCY.

Mr. Beamish asked the Chancellor of the Exchequer when the report of the Royal Commissioners on Decimal Currency, who were appointed in 1855, might be expected to be laid on the table?

The Chancellor of the Exchequer regretted that the report of the Royal Commissioners on this subject had not been made. The Commissioners were Mr. Hubbard, Lord Monteagle, and Lord Overstone; he knew that Lord Overstone's report was quite ready to be produced; he hoped the inquiry of the hon. member would lead to an early production of the report.

SUPERANNUATION BILL.

The House, after some discussion, passed this Bill through Committee.

BRITISH MUSEUM.

Mr. Gregory moved that a select committee be appointed to inquire how far, and in what way, it may be desirable to find increased space for the extension and arrangement of the various collections of the British Museum, and the best means of rendering them available for the promotion of science and art.

The House divided, and the numbers were:—

For the motion	21
Against it	2
Majority	—19

MONDAY, MARCH 21.

HOUSE OF COMMONS.

PATENTS FOR INVENTIONS (MUNITIONS OF WAR.)

The Attorney-General, in moving for leave to bring in a Bill "to amend the law concerning patents, with respect to inventions for improvements in instruments and munitions of war," said the measure was intended to accomplish a very important object. According to the present law, an invention when patented very soon became public, not only in this country, but, from the very liberal course adopted at the patent-office, abroad, for communications took place with foreign Governments and foreign societies, and the specifications thus became known throughout the world. Now, it was thought that inventions respecting munitions of war, or others of a character which it was for the public interest to conceal, should be vested in the Crown, or some of the officers of the Crown, say the Secretary for War. This, however, could only be effected by means of an Act of Parliament. The Bill would vest such inventions accordingly, and upon a declaration being made to the officers of the Patent-office power would be given to seal up all the papers connected with the invention, which would thus be kept secret as long as was thought advisable. To such a proposal there could, he thought, be no constitutional objection, because in ancient times it was the prerogative of the Crown to secure to itself an exclusive right to all inventions of a military character. The Bill was, therefore, only in furtherance of the ancient common law.

Leave was given to bring in the Bill, which was afterwards read a first time.

PATENT LAW AMENDMENT BILL.

A BILL TO AMEND THE LAW CONCERNING PATENTS FOR INVENTIONS WITH RESPECT TO INVENTIONS FOR IMPROVEMENTS IN INSTRUMENTS AND MUNITIONS OF WAR.

Whereas in some Cases of Inventions for Improvements in Instruments or Munitions of War it may be important to the Public Service that the Nature of the Invention should not be published, and it is therefore expedient to amend the Law concerning Letters Patent for Inventions: Be it enacted by the Queen's most Excellent Majesty, by and with the Advice and Consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the Authority of the same, as follows:

1. Any Inventor of any Improvement in Instruments or Munitions of War, or the Executors, Administrators, or Assigns of such, may, for valuable Consideration or without, assign to Her Majesty's Principal Secretary of State for the War Department, on behalf of Her Majesty, all the Benefit of the Invention, and of all Letters Patent obtained or to be obtained for the same, and such Secretary of State may be a Party to the Assignment, and such Assignment shall be effectual to vest the Benefit of such Invention and of such Letters Patent in the said Secretary of State for the Time being, on behalf of Her Majesty, at Law and in Equity; and the Benefit of such Invention and of such Letters Patent shall be deemed Property acquired by the said Secretary of State on behalf of Her Majesty; and all Covenants and Agreements contained in such Assignment for giving full Effect thereto, and for keeping the Invention secret, and otherwise in relation thereto, shall be valid and effectual (notwithstanding any Want of valuable Consideration), and may be enforced and proceeded upon by the said Secretary of State for the Time being accordingly, and all Actions, Suits, and Proceedings in relation thereto may be instituted and conducted by such Secretary of State for the Time being, who shall have all such Rights, Privileges, and Prerogatives in relation thereto as by Law provided in the Case of Actions, Suits, and Proceedings concerning Property under his Care, Control, and Disposition.

2. The foregoing Enactment shall extend to render valid and effectual, and be otherwise applicable to and in respect of any such Assignment as aforesaid made before the *passing of this Act*, and the Covenants and Agreements contained in such Assignment, as well as any such Assignment to be made thereafter, and the Covenants and Agreements therein contained.

3. Where any such Assignment as aforesaid has been made to the said Secretary of State he may, at any Time before the filing of the Petition for the

Digitized by Google

Grant of Letters Patent for the Invention, or after the filing of such Petition and before Publication of the Provisional Specification (if any), if he think it for the Benefit of the Public Service that the Particulars of the Invention, and of the Manner in which the same is performed, should be kept secret, certify the Fact of such Assignment having been so made, and his Opinion to the Effect aforesaid, in Writing under his Hand to the Commissioners of Patents for Inventions.

4. Where the said Secretary of State certifies as aforesaid the Petition for Letters Patent for the Invention, the Declaration accompanying such Petition and the Provisional Specification or Complete Specification (as the case may be) filed or left therewith, and any Specification to be filed in pursuance of the Condition of any Letters Patent for such Invention, and all Disclaimers and Memoranda of Alterations to be filed in relation to such Letters Patent, and any Drawings accompanying any of the Documents aforesaid, and any Copies of any such Documents or Drawings, or, where the said Secretary of State so certifies after the said Petition has been filed, such of the said Documents and Drawings as may be filed after his so certifying, and the Copies thereof shall, in lieu of being filed or left in the ordinary Manner in the Office of the Commissioners, or in the Office appointed for that Purpose under "The Patent Law Amendment Act, 1852," be delivered to the Clerk of the Patents in a Packet sealed with the Seal of the said Secretary of State.

5. Such Packet shall at all Times after the Delivery thereof to the Clerk of the Patents, until the Expiration of the Term or any extended Term for which Letters Patent for the Invention may be granted, be kept by him sealed up as aforesaid, or under the Seal of the Commissioners, save when it may be necessary to have Access to the Documents therein contained, or any of them, for the Purpose of recording and endorsing the Day of the filing thereof, or for the Purpose of any Reference to One of the Law Officers, either in relation to the same or any other Invention; but in any such Case as aforesaid the Clerk of the Patents shall not part with the Care or Custody of the said Packet, or any of the said Documents, save as may be required by One of the Law Officers for the Purposes of any such Reference, and shall use such Precautions as may be necessary to prevent the Contents or Particulars of any such Documents being improperly disclosed.

6. Such sealed Packet shall be delivered at any Time during the Continuance of any such Letters Patent to the said Secretary of State, or to any Person having Authority to receive the same on his Behalf, on Demand in Writing under the Hand of the said Secretary of State, or to such Person as the Lord Chancellor may order, and shall, if and when the same is returned to the Commissioners, be again sealed up and kept under Seal as aforesaid.

7. Such sealed Packet as aforesaid shall, at the End of the Term or extended Term for which any Letters Patent for the Invention to which the Documents in such Packet relate, be delivered up to the said Secretary of State or to any Person having Authority to receive the same on his Behalf.

8. Where the said Secretary of State certifies as aforesaid after the filing of the Petition, and before the Publication of the Provisional Specification (if any), such Petition, and the Declaration accompanying such Petition, and the Provisional Specification and Drawings relating to the Invention which may have been filed or left in any such Office as aforesaid, and all Copies thereof in any such Office, shall be forthwith placed in a Packet sealed with the Seal of the Commissioners; and every such Packet shall be subject to all the Provisions of this Act concerning any sealed Packet delivered to the Clerk of the Patents.

9. No Copy of any Specification, or other Document or Drawing by this Act required to be kept under Seal, shall be transmitted to Scotland or Ireland, or be printed, published, or sold, or be open to the Inspection of the Public; but, save as in this Act otherwise directed the Provisions of the Patent Law Amendment Act, 1852, and any Act amending the same, shall extend and be applicable to and in respect of every such Specification and other Document and Drawing as aforesaid, and the Letters Patent and Invention to which the same relates, and this Act and the Patent Law Amendment Act, 1852, shall be construed together as One Act.

10. It shall not be lawful for any Person to take Proceedings by Scire facias or otherwise to repeal any Letters Patent for any Invention in relation to which the said Secretary of State has certified as aforesaid.

11. The Secretary of State may, at any Time by Writing under his Hand, waive the Benefit of this Act with respect to any particular Invention, and the Documents and Matters relating thereto shall be thenceforth kept and dealt with in the ordinary Way.

12. The Communication of any Invention for any Improvement in Instruments or Munitions of War to the said Secretary of State, or to any Person or Persons authorised by him to investigate the same or the Merits thereof, shall not, nor shall anything done for the Purposes of the Investigation, be deemed Use or Publication of such Invention so as to prejudice the Grant or Validity of any Letters Patent for the same.

13. In the Construction of this Act, "Her Majesty's Principal Secretary of State for the War Department" shall mean Her Majesty's Principal Secretary of State for the Time being to whom Her Majesty shall think fit to intrust the Seals of the War Department.

WROUGHT IRON AND PUDDLED STEEL.

The whole of the evening meeting of the Institution of Civil Engineers, on March 8th, 1859, Joseph Locke, Esq., M.P., President, in the chair, was occupied by the discussion of Mr. Mallet's paper, published in our number for March 11. It was explained that Tredgold and other experimenters only gave the absolute forces which would tear a bar asunder. In Mr. Mallet's investigation an endeavour had been made to ascertain the amount of permanent elasticity possessed by the metal, as well as the point at which it would become actually ruptured. It was contended by one speaker that the drawings exhibited gave a very imperfect representation of the piling of the iron for large forgings, and that hence the author had been led to draw erroneous conclusions. With regard to the manufacture of the monster mortars, 36 inches in diameter, and capable of throwing a ball weighing about 30 cwt., it was remarked that their merits, as forgings, were extraordinary. At first, owing to large rents in the centre of the core, the forgings were failures, but after a little experience had been gained, the second forgings were quite successful. In the manufacture of these monster guns, they were built up in seven distinct layers, the forging occupying seven weeks. So far from any deterioration, or crystallization, taking place, the metal was improved by its long-continued heating and working; and the metal in the heart of the gun was found to be of greater strength than the bar iron of which it was composed, being perfectly homogeneous, strong, and tough. A series of experiments for testing the correctness of the process, showed that the ordinary manufacture of bar iron, by working and re-working several times, had its limits. As a proof that the deductions in the paper were incorrect, it was asserted by another speaker that engineers had one universal rule for the manufacture of forgings, whether large or small, and it was not found that the shafts of 1,000 H.P. engines were more liable to fracture than those of 100 H.P. This was practical evidence that the metal was not more deteriorated in large forgings than in small, from the length of time it was exposed to the action of the fire; indeed, no one portion was so exposed for any great length of time. It was urged that scrap iron, or any other highly refined iron, was the worst material for the construction of large forgings. It was considered that a strong, fibrous, fresh-puddled iron was superior in every respect, as the ordinary workings required in the process of forging would be sufficient to improve it to the average maximum of strength; whereas a highly-refined iron had already reached the highest point as regarded strength, so that it was more likely to be injured by additional working. There was another reason why scrap iron should not be used for the manufacture of forgings. Scrap iron was composed of many different qualities of iron, all having their own special welding points. When worked together, one portion, which was less refined, was too much heated, and consequently deteriorated, before the more highly-refined portions were at a welding heat; so that there was the difficulty either of burning the one or of being unable to weld the other. Again, the specimens selected by the author for trial, and which he said were weaker than the original iron composing the forging, were not taken off in the direction in which the fibre was laid for strength—in which it was intended that the strain should be borne. Now, forge-masters always laid the grain of the metal in the direction in which the strain would ultimately be applied; whereas, the samples experimented upon had been cut transversely to that direction.

With regard to the new material, "puddled steel," it was believed that it was destined to work a complete revolution in almost all matters in which iron had hitherto been used. It had been proved to possess at least double the tensile strength of the best wrought iron, and the elastic limit of the material was also greater in proportion to the breaking strain. A piece of this material had been subjected to a strain of 32 tons per square inch for seventeen consecutive hours, without exhibiting the slightest appearance of elongation. Subsequently, a bar, 4 feet in length and 1 inch by $\frac{1}{4}$ths inch in section, had been exposed to a strain of 45 tons per square inch, when it was found that an elongation of $\frac{1}{12}$ths of an inch had taken place. Upon the weight been removed, $\frac{1}{13}$ths of this elongation were recovered, showing that the elasticity of the material had not been destroyed. On another occasion the elongation amounted to $\frac{1}{75}$ths of an inch, and returned to $\frac{1}{100}$ths of an inch. Upon a second application of a strain of 56 tons per square inch, the bar was broken, the elongation having been $\frac{1}{27}$ths of an inch. In other experiments the bars broke at 55, 56, and 60 tons, and one bore the enormous strain of 87 tons per square inch. To attain this favourable result, which it was believed might eventually be accomplished as a rule, it was essential that great care should be taken in the selection of the materials, and great pains in the manufacture. It was entirely a question of good workmanship and good machinery; and a new manufacture of this sort would, for years to come, require the utmost attention and solicitude. In Germany, where this great improvement in metallurgy had been first introduced, a large number of manufacturers commenced making puddled steel; the consequence had been, that an amount of bad material had been thrown upon the market, which had brought puddled steel into disrepute for a time, and from which it had scarcely yet recovered. This was to be feared in this country, when the German patent had expired.

It was further contended that if the calculations in the paper had been based upon forgings, faggoted in the manner delineated in the drawings, they were of little practical utility. It was stated that large forgings, weighing 20 tons, and measuring 24 inches in diameter, for engines of 1,000 H.P., were now made at several places in England, without flaw or defect, except, perhaps, a small sand speck upon the surface, which was not of any consequence. When Nasmyth's hammer was first introduced, the plan was suggested of having the lower forge block made of a V shape, and the bottom part of the hammer so small as to strike only upon the upper centre of the periphery of the forged piece. The mass was thus struck in three places, and the tendency was to force the material to the centre, so as, in fact, to render the heart as solid and homogeneous as the other portions.

In reply to an inquiry, as to whether the rents in large iron forgings, spoken of in the paper, would not also be liable to occur equally in the puddled steel, it was said that in forgings of iron, large crystals or grains were developed, which would not be the case in similar masses of puddled steel; and that in the latter, the aggregation of grains or crystals was not increased by the agglomeration of the mass. These rents might be accounted for by the differential contraction of the metal. In the principal case referred to, the outside of the collar, which was four feet in diameter, cooled more quickly than the remainder of the forging, and these internal rents took place after it had left the hammerman's hand. It was stated that plates of puddled steel had already been supplied, from the Mersey works, for twenty-one vessels, some of them of 250 tons burthen and 38 feet beam. The thickness of the plates for the vessels for Indian river navigation was one-eighth of an inch, and none had yet been made, or called for, as a mercantile commodity of greater thickness.

CAST-IRON ARCHES.

At the Institution of Civil Engineers, March 15, the paper read was an "Account of Experiments upon Elliptical Cast-iron Arches," by Mr. T. F. Chappe, M. Inst, C.E. Joseph Locke, Esq., M.P., president, in the chair.

These experiments were undertaken at the request of Mr. W. H. Barlow, M. Inst. C.E., for the purpose of ascertaining, practically, the safe load to which elliptical cast-iron arches might be subjected, as well as the most economical distribution of the metal. The intrados of the arches was, in all cases, a segment of an ellipse, in order to obtain the greatest headway at the haunches. The experiments were in each case conducted upon two ribs, placed two feet apart from centre to centre, and resting on cast-iron abutment pieces, keyed up tight against the springings. Diagonal stays and longitudinal struts were also introduced to prevent lateral motion.

The first experiment was made upon a model, one-fourth the real size, of one arch of a bridge intended to be erected over the River Trent, near Newark.

Digitized by Google

The (model) arch had a clear span of 14 feet 6 inches, and a rise of 16 inches; a camber of ¼ of an inch being given in fixing the halves together. The sectional area of the arch at the crown was 2.43 inches—that of the curved rib near the springing two inches—about midway between the springing and the crown, 1.75 inch, and of the spandril, 1.34 inch. The weight of each arch was 1 cwt. 2 qrs. 22 lbs.

The other experiments were made upon a model, one-sixth the real size, of an arch erected over the Gloucester and Stonehouse and Great Western Railways, at Standish, six miles from Gloucester. The dimensions of the model were, span, 13 feet 10^3 in., and rise 1 foot 10 in. The sectional area, at the crown, was 1.25 inch, of the curved rib near the springing, 1.055 inch, about midway between the springing and the crown, 0.993 inch, about the middle of the upper rib, 0.883 inch, and of the spandril, 0.57 inch. The weight of each arch was 3 qrs. 26 lbs.

The following pressures were given as those to which the arches were subjected in these experiments:—

Experiment.	Ultimate Load.	How distributed.	Pressure per sq. inch of Sectional Area.	
			At Crown.	At Smallest Section.
	Tons. Cwt.		Tons.	Tons.
No. 1	30 10	Uniformly.	8·52	11·83
,, 2	18 0	Ditto.	6·89	8·58
,, 3	12 0	Partially removed from the haunches.	4·54	5·72
,, 4	5 0	On one haunch.	2·36	2·98
	3 12	At centre.	2·93	3·70
,, 5	3 14	Ditto.	3·00	3·85

In the first experiment, the ultimate pressure was not reached. In the second and third experiments, one-half arch was out of line laterally, beyond what would be permitted in practice, and was wanting in that assistance which would have been afforded, in the number of ribs required for the width of a bridge, so that the ultimate pressures indicated were below what such arches might be estimated to bear. This was also the case in the two last experiments, in which the castings were faulty, and the tests were such as were not likely to occur in practice. It was thought that cast-iron arches, of the form experimented upon, might safely be considered capable of bearing a pressure of between eight and ten tons per square inch of section. From the position of the fractures, it was believed that the spandrils were too weak, in proportion to the size of the arches.

The communication was accompanied by several tables, showing the deflections on the application of the different loads.

ON MILITARY AND OTHER TENTS.

By Major Godfrey Rhodes.*

THE subject of "tent-architecture" is one of very early origin; and although the necessity of supplying efficient shelter for troops in the field is at the present time fully acknowledged, yet little or nothing has been done towards accomplishing that requirement. It is a crying fact that enormous sums of money, and great encouragement are awarded for the perfection of destructive missiles; yet little or no encouragement, and but scanty supplies are granted towards (what ought to be the first step) supplying efficient shelter for the preservation of the health of our own troops when encamped in the field. The earliest mention we have of tents is in the 4th chapter of Genesis and the 20th verse, where we are told that "Jabel was the father of such as dwell in tents and of such as have cattle;"† evidently meaning that he was the inventor of tents, and of pitching those moveable habitations required for a nomadic life. We find after the flood, that Noah,‡ Lot,‖ Abram, and the two sons of Isaac (Esau and Jacob§), lived in tents; and although it is natural to suppose that, as "Esau was a cunning hunter and a man of the field," he required those portable dwellings, yet we find (Genesis, chap. 25,) that "Jacob was a plain man dwelling in tents," giving us sufficient evidence that tents were the earliest constructed habitations of man. It is impossible to ascertain with precision what was the peculiar form and construction of the Patriarchal tents; but, as the Arabs are so averse to adopting or deviating from the customs of their forefathers, we shall not be far from the truth, if we consider the present Arab tent the nearest existing approximation to the ancient model. To illustrate the subject, I will briefly describe the present Arab family-tent. Their most usual sized tent is from 25 to 30 feet long, by about 10 to 12 feet in breadth; it has nine poles. To pitch the tent, the three longest poles (viz. from 7 to 10 feet in length) are placed in the middle, at equal distances apart, and three of the others (about 5 or 6 feet long) are placed in like manner on each side; to the top of these, the black goat's-hair cloth, with which the Arabs cover their tents, is secured; and owing to the skill of the women, who manufacture all the tent coverings, even the heaviest rains do not penetrate this closely woven fabric. The side-coverings, or walls, are often of a coarse woollen cloth. The tent-coverings are kept stretched out in the usual manner, viz., by cords, which latter are fastened at one end to the top of the poles and at the other to pegs driven into the ground at the distance of three or four paces from the tent. The front of the tent is usually kept open, except during the winter, and the back and side hangings are so managed that the air can be admitted in any direction or excluded at pleasure. The weight of a tent of the above dimensions is about 1,500 lbs., or the load of two strong camels. I may mention that tents of much larger, and even smaller dimensions are used, according to the rank and wealth of the owner. It is not my intention to here enter into the minute details of the tents and coverings as used by the Israelites during their wanderings in the wilderness, as such would take up too much time, and perhaps afford but little interest to many of my hearers; but, as there is a diversity of opinion with reference to the various translations of the Hebrew words, "or, thakhash," which have been generally rendered badger-skin (such being supposed to have been used as the outer covering of "The Tabernacle"), I may mention that there is no certainty that the outer covering of the tabernacle must necessarily have been made of badger-skins: on the contrary, the commentators, as Jarchi, &c., raise the question whether any part of an unclean beast (and such is a badger) should or could have been used for the outer covering of that sacred building. The celebrated and generally correct historian Josephus, in his description of the offerings made by the Israelites when encamped at the foot of Mount Sinai, only states, "that the upper curtain was of a stuff that was proof against rain;" again, "that the outer covering was of skins, for a shelter against heats and rains, and for a fence against the injuries of the seasons." Niebuhr says that there is a fish in the Red Sea which the English call porpoise or sea-hog, and which is called by the Arabian merchants "dahash:" the skin is used for bucklers, and is said to be musket-proof. Other authors say the skins are used for covering huts, &c. It is well known that badgers do not now inhabit (if they ever did) the neighbourhood of Mount Sinai; and, as the porpoise is still to be found in the Red Sea under the name dahash, it may fairly be assumed that the "thakhash" of the Hebrew is the "dahash" or porpoise of the present day. The circumstance of the want of water in the wilderness, and the close approximation of the Red Sea to the sacred mount, may be of sufficient circumstantial evidence that the holy tabernacle was covered on the outside with the skin of the propoise and not with that of the badger. There is nothing very remarkable in the employment of fish-skins as an outer covering for tents, for the present day, the "Fishing or Alien Tuski," (a nomadic people who inhabit the extreme northern and eastern point of Asia, bordering on Behring's Straits) cover their tents with the prepared skin of the walrus, which is so beautifully cured as to retain its elasticity, and owing to its semi-lucent properties, sufficient light is admitted by the roof, to render windows quite unnecessary. Lieutenant Hooper, of the Royal Navy, who wintered amongst that tribe in 1848, when in the Plover, states, "that he saw a walrus skin of the enormous size of 70 to 80 square feet, and that the whole was as transparent as parchment." I may here mention that the Alien Tuski can raise the temperature of their tent to 90 and 100 degrees of Fahrenheit; they obtain this great heat by burning lamps filled with train oil, using the fibres of "weet-weet" or moss as a wick. Lieutenant Hooper says that there is neither smoke nor smell, when these lamps are well trimmed. There is another tribe called the Tungoozes, who cover their tents with fish-skins; these fishing-Tungoozes inhabit the south-eastern Siberian coasts, from the banks of the river Aldan (63° N. latitude, and 130° E. longitude), and a large river called by the Tungoozes, Okat, signifying, in a somewhat exclusive sense, "The River," which, flowing in a S.S.E. direction from the town of Yudomsk, and passing by Arki, emerges into the Okhotsk Sea, at the seaport town of Okhotsk (55° N. latitude and 143° E. longitude). With respect to the general form, and mode of constructing the tents of the numerous nomadic tribes which inhabit the earth, it is sufficient to say that their form is generally conical, sometimes with a centre-pole, but more often formed of straight poles having their upper extremities converging to one centre, and so arranged that a fire can be lighted within the tent, permitting of the smoke escaping through an aperture at the top. The various coverings or textures which are used for tents consist in camel's-hair cloths, rude felt, and goat-skin tissues, reindeer and buffalo skins, the birch-bark, chuco-leaf thatch, palm-mats, reeds, and sword grass, and the membranous and silky leaves of the vijao-plant; also a species of cloth made from the fibres of a root called lift-adum; the sailcloth of the modern Laplanders; and the sheltering ice-blocks of the Esquimaux; to say nothing of the brilliantly-coloured cloths, embroided velvets, and gold-starred satins which have decked the tents of kings, and chiefs, and conquerors in Europe and Asia, from the period of the middle ages down to the insignificant and shelterless canvas tents of the present day.

I will not enter into details of the tentology of the ancient Jews and Scythians, the Babylonians and the Egyptians, the Greeks and the Romans, neither the Kurds, the Tatars and Calmucs, the Turks and Esquimaux, Australs and Patagonians, nor the more modern systems of the great European States, such as France, Austria, Prussia, Russia, Sweden, Hanover, and Belgium, but will at once proceed to illustrate the British army tents of the present day. I will endeavour to explain their peculiarities of construction in detail, point out their general defects, call your attention to some very valuable remarks already recorded by professional men, having the object of directing public attention to the necessity of providing efficient coverings for our own troops when encamped in the field, and finally, will bring to your notice a proposed remedy, in the shape of a new system for constructing curvilinear and other tents of my own invention. The object I have in view is to endeavour to supply a practical remedy for an acknowledged and still existing deficiency.

The tents at present adopted in the British army consist of three, viz.:—First. "The Hospital marquee." Secondly. "The field-officer's marquee." Thirdly. "The circular single-poled tent." The hempen canvas of the hospital tent is supported by two vertical poles of nearly 14 feet each in length, secured together at their top ends by a ridge pole of 13 feet and 10 inches long. When the canvas has been stretched out, and secured to the ground by 184 pegs (which number includes the 4 large pins to secure the storm ropes), the canvas walls (5 feet and 4 inches in height) are hooked on to the bottom edge of the sloping canvas roof, and then pegged to the ground at that part which touches it. The roof and walls of this tent are of double hempen canvas, having a space between each of about one foot. The inside ground measurement of this tent is 29

MAJOR RHODES' HOSPITAL TENT.

[The description of this tent will appear in the concluding portion of Major Rhodes' Lecture.]

feet long by 14½ feet wide, and as it is understood to afford accommodation for not less than 18 or more than 24 men, it would, in the latter case, permit of 2 feet 5 inches by 6 feet 6 inches for each soldier, allowing 18 inches for a passage down the centre of the tent. This tent, when pitched, covers a space of ground 20 paces by 17, or about 340 square yards. The weight of these tents, when dry, varies from 428 to 507 pounds, and when wet, from 644 to 676 pounds. Or in other words, the weight increases about one-third, viz., in the former, the increase is 216 pounds against 169 pounds of the latter. It is thus evident that if the canvas was effectually rendered waterproof, greater efficiency and a large saving of transport would be the result. (See the table of sizes and weights of tents in the "Aide Mémoire to the Military Sciences," published in 1845-6.) A tent of the above dimensions contains 3,310 cubic feet of air, which would allow of about 275 cubic feet each to 12 men, about 183 cubic feet each to 18 men, and about 137 cubic feet each for 24 men. The hospital marquees are not provided with suitable means of ventilation.

(To be continued.)

AVERILL'S MILLS FOR GRINDING.

Mr. Thos. Averill, of Birmingham, has introduced an improved mill for grinding, constructed as shown in the accompanying engravings. Fig. 1 is a vertical longitudinal section, and Fig. 2 a plan, partly in section.

The grinding surfaces consist of a series of plates *a*, *b*, *c*, *d*, and *e*; *a*, *c*, and *e* being fixed, and the plates *b d* alternating with them moveable. Motion is given to the moveable plates by a crank *f* upon the axis *g*, which axis is driven by the pulley *h*. The moveable plates *b* and *d* are supported near the middle of their upper edges by means of a pin *i*, passing through a slot *k* in the said plates. By the rotation of the axis *g* and crank *f* the plates *b*, *d* are drawn backwards and forwards upon the pin *i*, and have besides an oscillating motion about the said pin *i* consequent upon the alternate elevation and depression of those ends of the said plates which are jointed to to the crank *f*. Both the fixed and moveable plates are corrugated, grooved, or otherwise roughened upon their surfaces, and the grinding is effected by the matter to be ground being operated upon by the corrugated, grooved, or roughened surfaces of the said plates. Each of the moveable plates *b*, *d* works between a pair of fixed plates. The size of the corrugations may be varied to suit different articles to be ground. The fixed plates *a*, *c*, and *e* are supported by the pins *i* and *i'*, and on the tops of the legs *l* of the machine. *m* is the hopper in which the substance to be ground is supplied. The said substance descends through the passage *n*, and passing through the slots *o* in the plates, falls between the said plates. The lower edges of the slots *o* in the plates are notched,

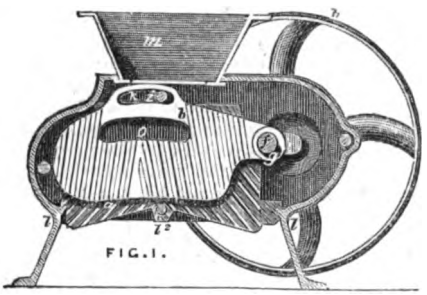

FIG. 1.

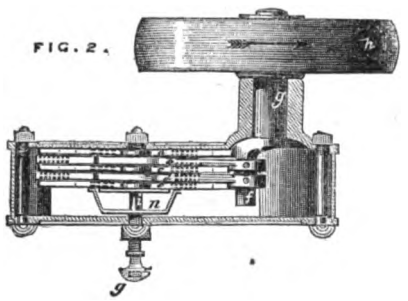

FIG. 2.

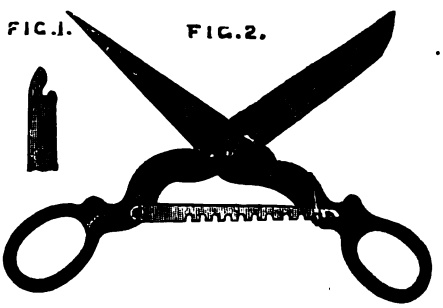
in order that the breaking of the coarser particles of the substance to be ground, and the introduction of their fragments between the plates, may be effectually secured. The upper edges of the plates, that is, the edges immediately below the slots *o*, are the thinnest parts of the plates, and the plates gradually thicken downwards, while the parts of the plates which constitute the ribs or projections are of uniform thickness. The grooves or depressions between the ribs are thus deepest at top, and become gradually shallower towards the bottom. The fineness or quality of the powder produced by the mill is determined by the set screw *q*, by driving home which said set screw *q* the distance to which the plates *a*, *c*, and *e* can separate is determined. The plates *a*, *b*, *c*, *d*, and *e* are made of cast iron or other metal or alloy sufficiently hard, and the frame or box in which the said plates work of cast iron. Although in the accompanying engraving we have represented a mill having but three fixed and two moveable plates, yet the number of the plates may be varied to any desired extent. The mill may either be worked as a hand-mill or be driven by steam or other power; and although it is particularly adapted for the grinding of grain, yet it may be employed for grinding coffee, pepper, spices, and for grinding generally.

Mr. Averill has patented his improved mills.

FISHING REQUISITES.

Mr. Rolfe, of Clement's-lane, City, the well-known piscatorial artist, has just given to the brethren of the "gentle craft" two very excellent inventions, the results of his own fertile brain. The one is a knife, the peculiarity and usefulness of which will be estimated by the drawing we give; and the other is a pair of scissors, both adapted to well-known emergencies in disgorging the hooks from a captured pike. The knife is likewise a dis-

FIG. 1. FIG. 2.



gorger, and permits of the actions of cutting and thrusting at the same time without a withdrawal of the instrument. The scissors serve all the purposes of the ordinary scissors, but having a racket and catch attached to the handle, when inserted in the fixed jaws of the pike, gradually extend its mouth, and the extension of the scissors being secured by the racket, keep it open for the necessary operations of detaching the line, &c. The knife, with a little alteration, would, we think, be

Digitized by Google

valuable to the butcher, and others, for flaying animals where the cutting and thrusting succeed each other so constantly. Both of these articles are procurable at Mr. Hills, the cutlers, in the Haymarket.

THE CONSERVATION OF FORCE.

(Continued from p. 107.)

GENTLEMEN,—The questions discussed by Mr. Grove are related to the very foundations of natural science. They relate, that is, to the knowledge of the material world attained by, and attainable to, the human mind. These questions have therefore a double character—psychological and physical. They cannot be completely investigated, nor satisfactorily solved, without examination of their connection with the nature and powers of the human mind as well as with the matter and forces of the external world. I have not the presumption to put myself forward as capable to prosecute so subtle and so arduous a task; and, had I the facility, I have not the leisure for the self-introspection, still less for the experimental and literary research which such a work would require, and my present want of leisure induces me to bring this series of letters to a somewhat abrupt conclusion. I propose, therefore, to make one or two concluding observations, first on Mr Grove's theory of electricity and light, and then, finally, on M. Seguin's views respecting impact, without attempting at present a thorough discussion of these subjects.

In endeavouring to show that heat, light, electricity, magnetism, &c., are all correlative forces, or affections of ordinary matter, Mr. Grove naturally addresses himself to solve the question, Has light, heat, or electricity any existence apart from and independent of ordinary ponderable matter? Of electricity, it has been the custom to speak as if it were a fluid substance, something resembling air or water, having an existence of its own, but unlike those substances, inasmuch as it neither increases nor diminishes the weight of the body to which it may be added, or from which it may be withdrawn. This hypothesis of a fluid has been suggested by that property of electricity by which it manifests itself in a line of motion like the swift flowing of a stream. There is another resemblance which electricity may be imagined to bear to the fluid substances of nature, viz., the equilibrium which it seeks to establish when two bodies in different electrical states are placed in communication. This feature resembles the equilibrium established when two vessels containing water at different levels are connected by a tube, or when two bladders of air at different pressures are connected in a similar manner. This, I think, is the simplest, though, perhaps, the most meagre of the various modifications of the electric-fluid hypothesis, and this to me is as much a figure of speech as a scientific theory. Mr. Grove, of course, favours an opinion adverse to this view, and certainly succeeds so far as to prove that no manifestation of electricity ever takes place except through the medium of ordinary ponderable matter. And he argues that since there is no experimental evidence of its separate existence, it may be regarded as one of the forces, affections, or qualities of matter, like gravitation or chemical affinity. This reasoning may be not altogether valueless, and, indeed, may have its use in showing the limits of our knowledge: but I do not see that it is of importance, whether we employ the phrase electric fluid or electric force. Electricity has relations to and distinction from both force and fluid as these terms are ordinarily understood. It is well known that electricity is nearly related to heat, light, magnetism, and chemical affinity. Everybody has seen the electric light with its intensely heaten charcoal points, the electro-magnet, and the electro-chemical experiments of the popular lecture-room. Mr. Grove endeavours to show that light may similarly be made to transform itself into heat, electricity, magnetism, and chemical action. This attempt, however, he himself seems to regard as rather unsuccessful. Photography is adduced to show that light produces chemical action, but it does not appear to me satisfactory to conclude that it is the light or luminous portion of the sun's rays which produces the photographic effect, when we know that those rays are composite. The sun's rays, according to some, are made up of a mixture of light, heat, and a principle called actinism, producing chemical action. The philosophers who hold this view regard the photographic agency as a principle of the sun's rays, independent of both the light and heat which accompany it. The following experiment, used as evidence of the truth of the same proposition, for a similar reason is equally weak:—

"Light would seem directly to produce heat in the phenomena of what is termed absorption of light: in these we find that heat is developed in some proportion to the disappearance of light. To take the old experiment of placing of different coloured pieces of cloth upon snow exposed to sunshine, the black cloth absorbing the most light, and developing the most heat, sinks more deeply in the snow than any others; the other colours, or shades of colour, sink the more deeply in proportion as they absorb, or cause to disappear, the more light, until we come to the white cloth, which remains upon the surface."

This may be partially, or even wholly, a correct explanation of the experiment cited. But its truth or its falsehood is by no means apparent; and it cannot, therefore, be made a ground of argument. Why may not the pieces of cloth which reflect or absorb most light coincidently reflect or absorb most heat? And why, therefore, may not the whole effect of the sinking of the black cloth be due to the heat which it receives from the sun's rays, and have nothing to do with the light at all? I am hardly competent to offer an opinion on this subject; but I may say that the argument is inconclusive—as, indeed, Mr. Grove himself admits.

The following extract will exhibit Mr. Grove's theory of light in another aspect:—

"Light was regarded, by what was termed the corpuscular theory, as being in itself matter or a specific fluid emanating from luminous bodies, and producing the effects of sention by impinging on the retina. This theory gave way to the undulatory one, which is generally adopted in the present day, and which regards light as resulting from the undulations of a specific fluid to which the name of ether has been given, which hypothetic fluid is supposed to pervade the universe, and to permeate the pores of all bodies.

"In a lecture delivered in January, 1842, when I first publicly advanced the views advocated in this essay, I stated that it appeared to me more consistent with known facts to regard light as resulting from a vibration or motion of the molecules of matter itself, rather than from a specific ether pervading it; just as sound is propagated by the vibrations of wood, or as waves are by water. I am not here speaking of the character of the vibrations of light, sound, or water, which are doubtless very different from each other, but am only comparing them so far as they illustrate the propagation of force by motion in the matter itself.

"I was not aware, at the time that I first adopted the above view, and brought it forward in my lectures, that the celebrated Leonard Euler had published a somewhat similar theory; and though I suggested it without knowing that it had been previously advanced, I should have hesitated in reproducing it had I not found that it was sanctioned by so eminent a mathematician as Euler, who cannot be supposed to have overlooked any irresistible argument against it,—the more so in a matter so much controverted and discussed as the undulatory theory of light was in his time.

"Although this theory has been considered defective by a philosopher of high repute, I cannot see the force of the arguments by which it has been assailed; and therefore, for the present, though with diffidence, I still adhere to it. The fact itself of the correlation of the different modes of force is to my mind a very cogent argument in favour of their being affections of the same matter; and though electricity, magnetism, and heat might be viewed as produced by undulations of the same ether as that by means of which light is supposed to be produced, yet this hypothesis offers greater difficulties with regard to the other affections than with regard to light; many of these difficulties I have already alluded to when treating of electricity; thus conduction and non-conduction are not explained by it; the transmission of electricity through long wires in preference to the air which surrounds them, and which must be at least equally pervaded by the other, is irreconciliable with such an hypothesis. The phenomena exhibited by these forces afford, as I think, equally strong evidence with those of light, of ordinary matter acting from particle to particle and having no action at a distance. . . . ."

"The analogies in the progression of sound and light are very numerous: each proceeding in straight lines until interrupted; each is reflected in the same manner, the angles of incidence and reflection being equal; each is alternately nullified and doubled in intensity by interference; each is capable of refraction when passing from media of different density. This last effect of sound, long ago theoretically determined, has been experimentally proved by Mr. Sondhauss, who constructed a lens of films of collodion, which, when filled with carbonic acid, enabled him to hear the ticking of a watch placed in one focus of the lens, the ear of the experimenter being in the opposite focus. The ticking was not heard when the watch was moved aside from the focal point, though it remained at an equal distance from the ear."

Both Mr. Grove's and the etherial hypotheses appear to me incomplete. To complete them, it is necessary to show how, by means of different modes of vibration of ordinary matter, the characteristic effects of light, heat, magnetism, electricity, &c., may be produced. Each is rather a hint at an hypothesis than a definite supposition. A mere fragment of an hypothesis seems to me of very little use, and it is hardly worth while to dispute about the relative merits of these two. I see but little to choose between them. If the phenomena of conduction and non-conduction introduce difficulties in the etherial theory, they make equal difficulties in Mr. Grove's own hypothesis. If it be hard to understand how the electric ether will propagate its motions better through copper wire than through glass or atmospheric air, it is equally hard to conceive why copper should communicate its electric vibrations more readily to water than to wax.

The analogies between the phenomena of light and sound, given by Mr. Grove, are striking enough, especially the last which he cites. But to say that they are both propagated in straight lines is hardly correct, for sound, even in a uniform medium, makes no difficulty in turning the sharpest corner, whereas light, if left to itself, will scarcely turn a corner at all. This is, indeed, the grand distinction between light and sound. And this has always been a difficulty with me in forming a notion of the undulatory hypothesis, for I have never been able to conceive the kind of vibration which would confine the propagation of itself through a uniform medium to the right-lined method in which light proceeds. There is one objection to the theory of light advanced by Mr. Grove, which I must not pass over unnoticed, and which Mr. Grove himself acknowledges to be of considerable weight. I cannot do better than quote partially his own statement of it, he says:

"An objection to which the view I have been advocating is open, and a formidable one, is, the necessity involved in it of a universal plenum; for if light, heat, electricity, &c., be affections of ordinary matter, then matter must be supposed to be everywhere where these phenomena are apparent, and consequently there can be no vacuum.

"These forces are transmitted through what are called vacua, or through the interplanetary spaces, where matter, if it exist, must be in a highly attenuated state.

"It may be safely stated that hitherto all attempts at procuring a perfect vacuum have failed. The ordinary air-pump gives us only rarefied air; and by the principle of construction, even of the best, the operation depends upon the indefinite expansion of the volume of air in the receiver; even in the vacuum which is formed in them, so great is the tendency of matter to fill up space, that I have observed distilled water contained in a vessel within the exhausted receiver of a good air-pump has a taste of tallow, derived from the grease, or an essential oil contained in it, which is used to form an air-tight junction between the edges of the receiver and the pump-plate." . . . .

"Sir W. Herschel's experiments go to prove that the sun and Jupiter have dense atmospheres, while Wollaston's were believed to prove that they have no appreciable atmospheres.

"If it be admitted, or considered proved, that the sun and planets have atmospheres—and little doubt now exists on this point—then the grounds upon which Wollaston founded his arguments are untenable, and there appears no reason why the atmosphere of the different planets should not be, with reference to each other, in a state of equilibrium. Ether, or the highly attenuated matter existing in the interplanetary spaces, being an expansion of some or all of these atmospheres, or of the more volatile portions of them, would thus furnish matter for the transmission of the modes of motion which we call light, heat, &c.; and possibly minute portions of these atmospheres may, by gradual changes, pass from planet to planet, forming a link of material communication between the distant monads of the universe." . .

". . Of the existence of matter in the interplanetary spaces we have some evidence in the diminished periods of comets. . ."

To all this I can merely say that I have a sort of antipathy to the idea of the existence of ponderable matter in the interplanetary spaces. Certainly the diminution of the periods of comets is no evidence of such existence, for this diminution may perhaps be accounted for by the disturbances produced by the presence of the planets themselves upon those mysterious strangers.

Yours, &c., A MECHANIC.

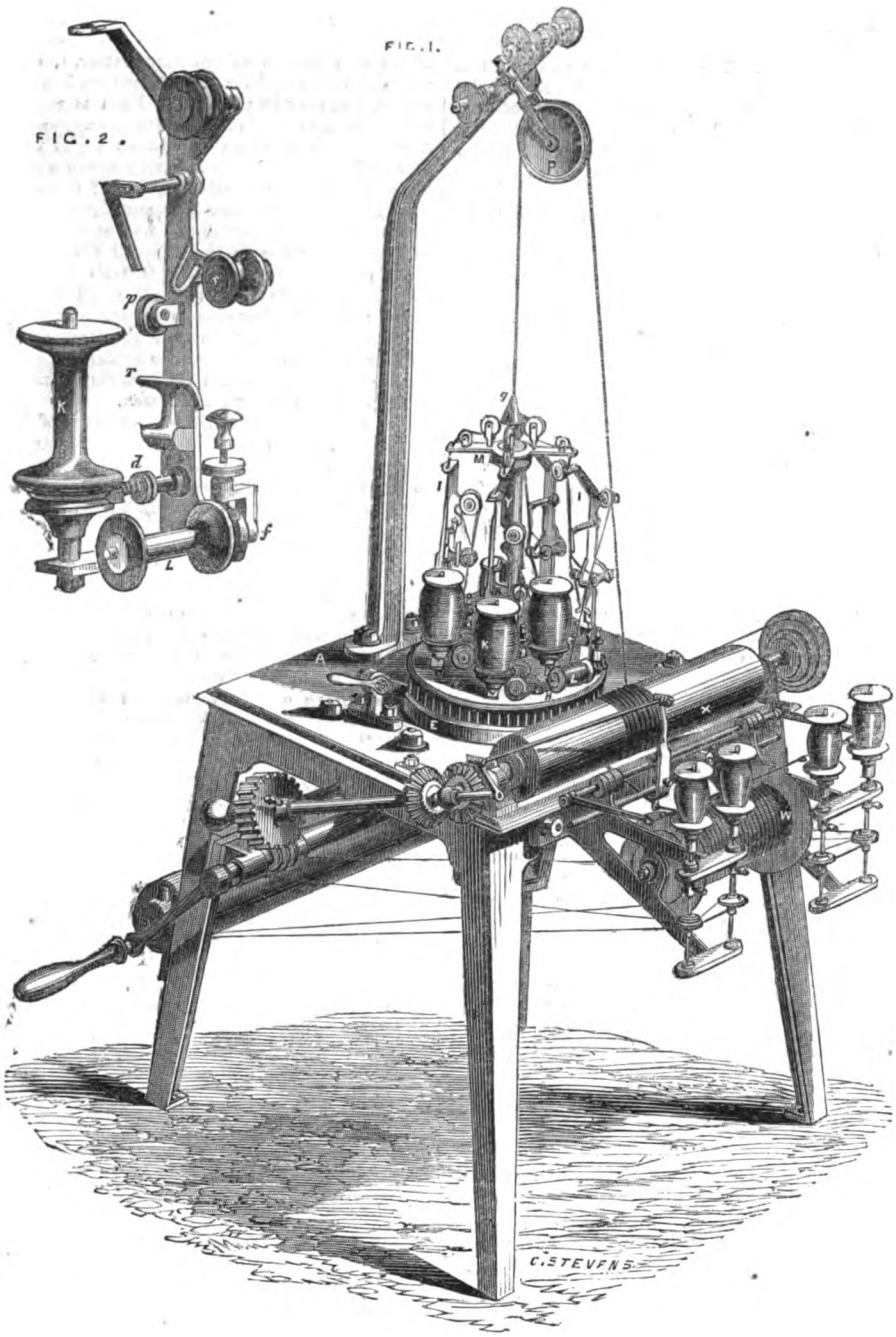
ZAHN'S MACHINE FOR MAKING COVERED OR PLATED TWIST OR CORD.



ZAHN'S MACHINE FOR MAKING COVERED OR PLATED TWIST OR CORD.

MR. JOSEPH LEWIS, engineer and machine-maker, of High-street, Bloomsbury, is manufacturing a highly-ingenious machine for making the material known as covered or plated twist or cord. The machine is extremely compact, and is capable of being worked with great rapidity, so as to produce the finished twist or cord in large quantities and with a small expenditure of power.

By this machine cotton, hemp, &c., may be covered, or, as it is technically termed, "plated," with silk or worsted, or any suitable fibrous or textile material may be twisted and covered or plated with the same or a different material, and, if desired, afterwards laid to make cord at one and the same operation. Fig. 1 of the annexed engravings is an elevation of the machine. *A, A* is a table or stand for supporting the upper framework of the machine; *C* is a shaft with two journals and bevel wheels, which, conjointly with a double clutch movement, gives motion to and controls the centre spindle or cylinder *Y*, and engages or disengages the plates *E* and *H*. For the fabrication of the plated twist, the upper plate *H* is stationary, and the lower one *E* only revolves. *I, I* are the flyers, of which there are supposed to be four, but may be a greater or less number. An enlarged view of one of these flyers is shown detached in Fig. 2. Each of the flyer spindles carries a spur or cog wheel placed between the two plates *H* and *E*, which gears with a circular rack composed of a series of upright studs secured in the bottom of the lower plate *E*. Each flyer carries two bobbins, a large one, *K*, carrying material to form the interior or core of the twist or cord, having its axle supported by the bottom of the flyer; and a smaller one, *L*, carrying the material for the plating or covering, having its axle secured at one end in an arm *f* attached to one side of the flyer. The bobbin *K* has on the side of it a spring of any suitable material with a metal washer intervening. This spring is operated upon by the set screw *d* for the purpose of regulating the supply of the warp, and the bobbin *L* has a similar set screw attached to a spring for regulating the supply of silk to the warp. The flyer is furnished with pulleys and guide pieces as shown in the detached view Fig. 2, for spreading the silk covering upon the cotton core. Attached to the flyer, and nearly central with the bobbin *K*, is a double hook *r*, which, receiving the cotton from the bobbin *K*, serves as a guide to keep the cotton off the bobbin, and leads it to the pulley *p*, as well as to prevent the cotton warp from twisting before it passes the hook. This pulley *p* is for the purpose of improving and rounding the cotton twist preparatory to its receiving the silk, and at the same time keeping the twist in one position. On the centre of the plate *M* is fixed a conical guide *g* for the better laying of the cord. This guide can be elevated or depressed according to the angle the twist is to assume to form the cord. On the side of the guide are grooves along which the twist travels, and immediately the twist leaves the said guide the strands join together and the cord is formed. A moveable guide with rollers may be used to accomplish the same purpose as the conical grooved guide. This guide being for the purpose of confining the strands to the requisite angle causes unity of motion, regularity of cord, and prevents vibration. The warps may consist each of a sufficient number of threads or rovings or of a single thread or roving of a proper size. Each passes upwards from its bobbin over its respective roller, to which it is guided by means of the hook, &c., thence being conveyed over the guide rollers and conical guide, above which the several covered threads or strands are laid together, passing then upwards over the speed regulator *X*, from which it is received by a winding-off spool *W*. The covering consists of a number of filaments arranged together so as to lie parallel and form a flat sliver or ribbon; it passes from the bobbin *L* to meet the warp at the junction of the two spreading hooks. In making laid cord composed of covered strands, the lower plate *E* is made stationary by inserting the pawl *x*, and rotary motion is communicated to the spindle *Y* of the flyer frame. The flyer frame being fast on its spindle rotates with it, and the wheels of the flyers, by revolving in gear with the stationary rack, receive rotary motion on their own axis, and cause the flyers *I, I* to rotate. The rotary motion of the flyers gives a slight twist to the warps as they are unwound from their bobbins by the speed regulator *X*, and at the same time causes the covering or plating sliver or ribbon to be wound round them. The winding on of the covering or plating takes place where it first meets the warp, and as it takes place always at the same point, must be uniform. The covering is laid smooth by passing over the guide rollers, and spread to its utmost by means of the spreading hooks, as the winding is performed. The rotary motion of the flyer frame lays and twists the several covered strands together, and forms the cord in substantially the same manner as common cord is formed in machines heretofore employed for that purpose.

If it be only required to make plated twist, such as is used for tassels, fringes, &c., the several warps, instead of being laid together after they are covered, are conducted to separate reels or spools, as each in itself constitutes what is known as plated twist. In that case, however, the flyer frame is made stationary by shifting the pawl. In making covered or plated cord, this machine does at one operation what by the usual process of manufacture requires five distinct operations, and it is estimated that by it the manufacture can be carried on in less than one-thirtieth of the space required for the same amount of work by the means now in use. The operation will be still further expedited by employing two or more bobbins *L* in each flyer to carry the covering material, each bobbin being arranged and operating like the single one represented and described.

The above description refers to a vertical machine, but the same result may be arrived at and accomplished by making it horizontal.

The machine was patented some time since by M. Zahn, and has had its details improved by Mr. Lewis.

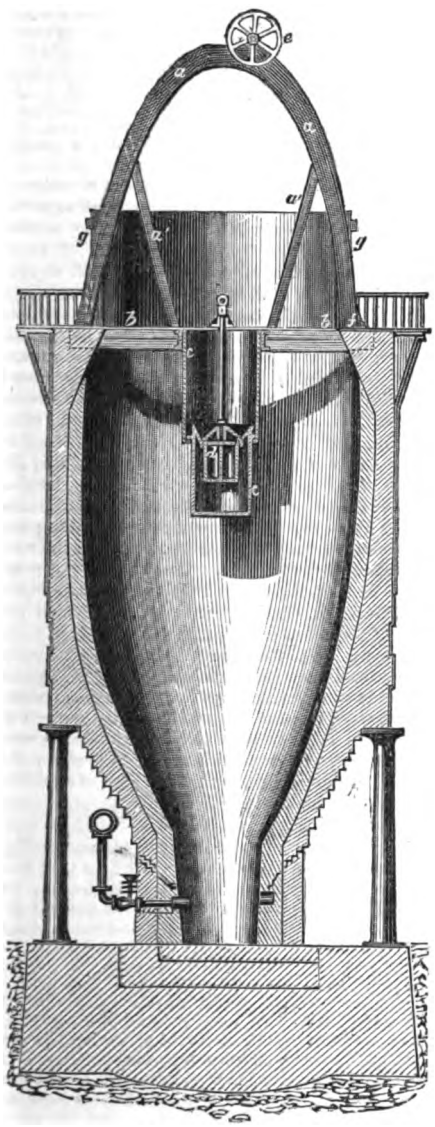
SLATE'S IMPROVED BLAST FURNACE.

IN smelting iron ore, the usual practice has been to feed in the whole of the materials together at the mouth of the furnace, that is to say, throwing in first a barrow load of fuel, then one of ore, afterwards one of lime or flux, and so on, according to the proportions in which the different materials are employed. Mr. Archibald Slate, of Haverstock-hill, London, has introduced an improvement, according to which he makes the mouth of the furnace much wider than usual, and places a bridge supported by iron girders across it; from this bridge a cast-iron pipe descends vertically into the furnace, and is continued a

Digitized by Google

considerable distance downwards beneath the surface of the materials in the furnace. In working the furnace, the greater portion of the fuel is fed in through this pipe, and the other materials are fed to the open mouth of the furnace, as heretofore, exterior of the pipe, and all round it.

The annexed engraving is a vertical section of the furnace. *a*, *a* are arched girders passing across the mouth of the furnace, and from them are suspended by the bars *a'*, *a'* the bridge *b*; from it descends into the furnace the cast-iron pipe *c*, which for convenience he makes in two parts, so that the lower portion, which is most exposed to heat, may when it becomes worn be readily removed without interfering with the



upper portion of the pipe. The lower portion of the pipe is lined with fire-brick, as is shown. It contains within it a valve *d*, which is furnished with a rod, and by a chain attached to the rod, and passing over the pulley *e*, the valve may be raised when desired. Round the top of the furnace is a gallery *f*, and there is a screen wall *g*. Round its inner edge are scuttles or passages, by which the materials are introduced into the top of the furnace exterior to the pipe *c*. In working the furnace the inventor introduces into it by the side scuttles the ore and the lime or flux together, with, by preference, about one quarter of the whole of the fuel employed, and this either in the form of coke, or it may be of raw coal. The remainder of the fuel is fed into the pipe *c*, by preference in the form of small coal, and after each barrow load has been tipped into the pipe, the valve *d* is raised to allow the fuel to descend. When this valve is closed it prevents the draught of the furnace ascending the pipe *c*, and compels it to pass up all round through the ore and lime.

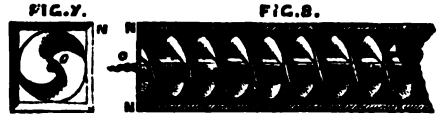

FIG. 9.

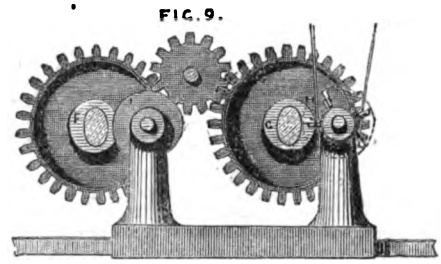

FIG. 12.

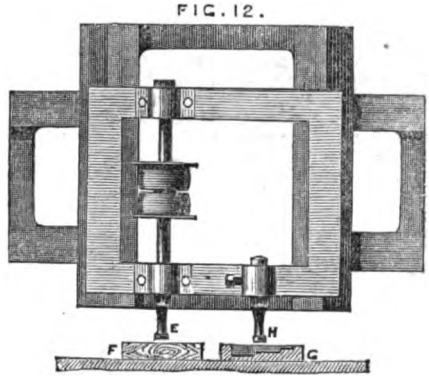

FIG. 10. FIG. 11.

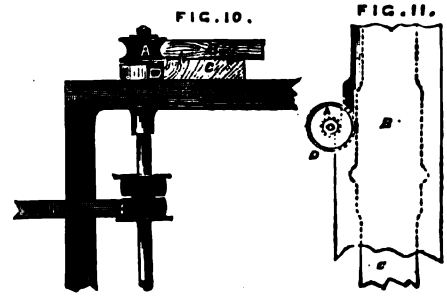

MACHINERY FOR TURNING.

ON SOME APPLICATIONS OF THE COPYING OR TRANSFER PRINCIPLE IN THE PRODUCTION OF WOODEN ARTICLES.

By John Anderson, Esq., F.R.S.,
Inspector of Machinery, Woolwich Arsenal.

(*Concluded from p.* 190.)

The machinery for effecting this object is variously arranged; one of the best combinations is shown in Fig. 6. The head stock containing the cutter, *A*, in addition to the revolving motion of the spindle has a longitudinal movement imparted to it by means of the grooved cam *B* and the lever *C*; the wooden rod to be cut, *D*, being held firmly by the saddle, *E*, the headstock and cutter are gently pushed against its extremity, thus forming the conical end to the rod, and are then withdrawn again.

The second operation is to cut off the plug. To accomplish this the bed and saddle, *E*, carrying the wooden rod, *D*, are placed upon the top of a rocking frame, which also is moved by a cam, *F*, and connecting rod, *G*, but in a direction at right angles to the sliding motion of the headstock. When the conical end has been formed and the headstock drawn back, the woodholder, *E*, is pushed transversely against the circular saw, *H*, and the finished plug drops into a box, *I*; after which the saddle, *E*, is brought back into line with the headstock, and an intermitten self-acting feed motion, *K*, pushes the rod of wood forward into the position for forming another plug.

In some of the earlier machines the saw made a transverse movement to cut off the plug; by that arrangement the plugs and the chips were mixed together in the same heap, and the labour for their separation cost more than for the manufacture; but by the new arrangement, the plugs and the chips are kept separate, and the cost in wages is thereby reduced more than one-half.

A modification of the copying principle employed in a machine for forming square holes or mortices in wood is another example.

It consists of a combination of a square box-chisel with a screw augur working within it, shown in Figs. 7 and 8. The chisel, *N*, forms a square socket of the same external dimensions as the required mortice, having its four cutting sides chamfered inwards. Within this chisel and combined with it there is a revolving screw augur, *O*, having an independent circular motion, its cutting edge being flush with that of the chisel. The action of the machine consists in forcing the square chisel against the wood with a pressure sufficient to make an incision, and the augur drills out about ⅞ths of the required hole, the chisel making the round hole square, and with its bevelled edges pushing the chips against the running augur, by means of which they are withdrawn.

The Blanchard turning lathe contains a modification of the copying principle, susceptible of endless application in the production of irregular forms; it is used in turning gun stocks, spokes of wheels, shoe lasts, busts, and similar articles.

It may be described as two lathes placed side by side and parallel with each other, as shown in Fig. 9, the one lathe containing the pattern *F*, the other the lump of material, *G*, out of which the article is to be formed, and both lathes having the same motion. The sliding rest which holds the turning tool *H* also carries a dumb instrument, *I*, for tracing the pattern

Digitized by Google

F, and by means of a weight or spring this tracer is kept in contact with the pattern. As usually constructed the turning tool, *H*, consists of a revolving wheel, having its periphery fitted with cutters, and driven by an independent strap at about 2,000 revolutions per minute. The tracer, *I*, is also of the same external circular shape and size as the tool, and is capable of turning freely on its axis. The action of the machine consists in imparting to the cutter *H* the motion of the tracer *I*, as produced by the irregular surface of the pattern *F*; the tracer being in contact with the pattern, as the latter turns round the tracer moves out and in accordingly; and as the material, *G*, in the second lathe has the same motion as the pattern, and the cutter has the same outside form as the tracer, it necessarily produces the same shape as the pattern; and the slide rest that carries the cutter and tracer being made to slide along in the usual manner brings out the required copy of the pattern, one man being able to attend on several machines.

The Blanchard lathes employed in the workshops of the War Department are variously constructed: in some the cutter and tracer are both mounted on a transverse slide rest; in some they are suspended like a pendulum; in another, which is found to be a very superior arrangement, the tracer and cutter are mounted together on a rocking frame, the centre of motion being near the floor. By both the latter modifications the friction is greatly reduced, and the action is more delicate in tracing the exact outline of the pattern than with the slide-rest motion.

A wheel fitted with cutters similar to that used in the Blanchard lathe has been employed with great advantage in forming different curves by means of a single instrument. This is done on the principle that if a piece of wood is passed under the cutting wheel in a line parallel with the axis of the wheel it will form a groove corresponding with the circle of the wheel's circumference; but if the wood is passed along the face of the cutting wheel it will produce a flat surface. Curves between these two extremes are obtained by adjusting the apparatus to intermediate angles.

The manufacture of scabbard linings affords another illustration of this copying principle. The wood is first cut roughly into shape by means of the endless band saw. The next operation is to shape one side of the exterior surface: to accomplish this the rough piece of wood is laid in a wooden holder which is susceptible of a longitudinal movement, and which by means of guides is constrained to describe a curve the same as that of the scabbard; this movement is made under a revolving cutter having the transverse shape of the scabbard; the two combined motions produce the required form. The other side is formed exactly in the same manner, the finished side being laid in a holder of the exact form, in order to have the two sides placed exactly opposite to each other. These two operations complete the exterior. The third operation is to cut out the receptacle for the sword: the wood already shaped externally is laid in a holder, into which it fits firmly, this holder being made to move in the proper curve under a revolving cutter the shape of the sword. It is then placed in a fourth holder over a circular saw to widen the upper end in order to receive the thick part of the sword; after which the end is laid under a circular knife having a vertical movement by means of which the point is cut to the proper shape. The accuracy of manufacture by this method is of course greatly superior as compared with the system of hand labour by means of which they have been made hitherto; also the rapidity of manufacture is greatly increased, two boys being able to produce 500 scabbard linings daily.

The same combination of movements is frequently arranged in a different manner, by means of which mouldings or such work can be formed on the edge of irregular surfaces. The circular cutter of the required form is placed on the top of a vertical revolving spindle, as shown at *A*, Figs 10 and 11. The piece of wood, *B*, to be operated upon is fixed to a holder, *C*, which has been cut to the shape in the longitudinal direction. The operation consists in pushing this holder against a fixed collar, *D*, surrounding the spindle; consequently a combination of the form of the holder and also of the cutter is transferred to the piece of wood.

In the Small Arm Factory at Enfield, that intricate piece of mechanism, the gun stock, is produced entirely by machinery. It will be well understood how very difficult it is to make such articles perfect both in form and dimensions; it is comparatively easy to make things nearly correct, but to attain to perfect fitting from the machine involves conditions which are not ordinarily realised. With the machinery in question this absolute fit is secured at the rate of from 1,000 to 1,200 gun stocks per week, leaving only the exterior smoothing to be done by hand. The object of the present paper is not to describe the machines in detail, but only the principle of cutting; for it requires upwards of a dozen machines to produce a gun stock, each being differently arranged to suit its special operation; but the general principle in all is the same, and if understood may be readily applied in an infinite variety of ways for the performance of other operations.

The cutting out is effected by means of a revolving bit or drill, *E*, as shown in Fig. 12, made in the required form and driven at a great velocity, 6,000 revolutions per minute; this being kept very sharp is capable of producing a clean smooth hole, and if pushed against the wood, *F*, sideways, or the wood pushed against the drill, will cut its way in any direction. In order to guide the drill in cutting out the required shape, there is placed alongside the gun stock, *F*, a hard steel pattern, *G*, of the required form; and upon the frame which carries the drill, *E*, there is fixed a dumb tracer, *H*, of the same external form as the drill. This tracer being connected with the same framework as the drill, and both having the same vertical or horizontal movements, it follows that if the tracer is brought into contact with the pattern, *G*, the drill will be brought into contact with the wood, *F*, and will drill its way accurately according to the truth with which the tracer is pushed round the pattern.

Owing to the intricate form of the gun lock, bits of different sizes are required to cut out the wood to fit it correctly: this is effected from a single pattern in the following manner. The machine is provided with a number of revolving bits of different dimensions, each accompanied by a tracer of exactly the same external form; and the machine is so constructed that each in succession can be brought into operation. At the commencement the larger bits are introduced; these clear out wherever the larger tracers can find an entrance into the pattern; and having done their part, the smaller bits are substituted, and at last a very delicate drill for touching off certain points too minute for its predecessors. Thus the whole operation is accomplished with the most rigid accuracy, and with a rapidity truly wonderful; for, including the fixing of the stock and the several changes of the drills, the whole may be performed under a minute.

The question naturally suggests itself, How can this accuracy be secured, seeing that the revolving drills are more liable to wear than the dumb tracers, and that such a condition must necessarily alter the dimensions of the recess produced by the drills, even if it give the proper shape? The method of compensating for wear is very ingenious and deserves to be generally known. The conical hole in the end of the running spindle into which the drills are fitted is made very slightly eccentric; the drill is also made eccentric on its shank to the same amount. Both the end of the spindle and the drill are graduated round the circumference. When the drill is new it is set to run truly central, by placing the two eccentricities opposite to each other, and thus to cut out its own diameter; but as by continued sharpening it necessarily wears, the time arrives when it requires to be altered in its position in the spindle, by throwing it slightly out of centre; and owing to the high velocity with which it revolves, any disadvantage arising from the eccentricity in the working is not perceptible, while the accuracy and correctness of the fit are rigidly maintained.

LONDON FIRES IN 1858.

TWENTY-EIGHTH ANNUAL REPORT.

By Mr. WM. BADDELEY, *C.E., Inventor of the Portable Canvas Cisterns, Farmers' Fire-engine, Improved Jet-spreaders, &c.*

"The statistics of London fires are by no means devoid of interest, and the time may come when they will form an index to the social advancement of the people; for, in proportion as houses are built more and more fire-proof, and habits of carefulness become more and more diffused, the number of destructive fires will assuredly lessen."—*Knight's London.*

(*Concluded from page* 192.)

THE fires in many provincial towns, as well as in the metropolis have been of a very serious character during the past year.

Mr. Hewitt in Liverpool, and Mr. Rose in Manchester, have had fires enough to keep their fire police in good working order; while Plymouth has afforded frequent opportunities for Mr. Marshall to continue to distinguish himself by his masterly management of the West of England Fire Brigade.

Wynnstay Hall, the ancient family mansion of Sir William Watkins Wynn; Trowscoed Hall, North Wales, the seat of E. S. R. Trevor, Esq.; and Donibristle House, the seat of the Earl of Moray, in the Firth of Forth, have all fallen victims to the devouring element. Two railway viaducts, one near Stafford on the Trent Valley line, the other on the Selby and Market Weighton railway, have been destroyed by locomotive cinders falling between the wood-work. The Salisbury station of the South Western Railway Company has also been burned down, as is supposed through a defect in the flue of the waiting room. A very important improvement in the construction of fire-proof floors and roofs has been perfected and patented recently by Mr. Bunnett, of Deptford, whose numerous inventions and improvements in connection with the engineering department of buildings is so well known. The present improvement consists in the employment of a hollow brick so formed that each brick supports and is supported by the six bricks which surround it, by which means immense strength is obtained; tie-rods are passed under, or through the hollow bricks to wall-plates of angle iron, so as to relieve the walls of any thrust. Arches may be constructed either quite flat, or with a very trifling rise, by means of these bricks, at an expense slightly, if anything, greater than ordinary floors. Mr. Bunnett has also designed a light metallic staircase, of a simple and cheap construction, to be used in conjunction with his brick floors and roofs; so that fire-proof houses stand a fair chance of becoming general; if they do not, it will not be on account of the expense. The term "fire-proof" must be taken in a qualified sense; no buildings can be strictly "fire-proof," because calorie will calcine stone and fuse iron. In warehouses filled with masses of combustible materials the amount of heat is often irresistible, but in ordinary dwelling-houses where there is nothing beyond the usual articles of furniture to burn, there seems now to be no difficulty in obtaining a practically fire-proof building at a moderate cost.

At a meeting of the St. Pancras vestry, in October last, a vestryman called attention to "the dreadfully unprotected state of the northern districts of the metropolis for want of fire-engines in case of fire," and thought that an application from that vestry, representing a parish containing 200,000 inhabitants, might have some effect on the insurance companies; he therefore moved, "That the attention of the fire-insurance offices of London be called to the requirement of a fire-brigade establishment in Camden or Kentish-towns." The motion, of course, was carried unanimously, and doubtless "had the effect" on the insurance companies (especially of those who keep no firemen or engineers) of exciting their laughter at the selfishness and ignorance of the parishioners of St. Pancras, who are continually calling upon Hercules to help them, but never put their own shoulders to the wheel. The St. Pancras people complain that there is not a single brigade engine-station north of Holborn! A fact which only reflects the more disgrace upon themselves, for not supplying by proper local arrangements this notorious and lamentable deficiency. In St. Pancras, which is one of the largest metropolitan parishes, the authorities are so apathetic as regards the calamities of fire, that they provide but a single engine, kept in an obscure part of the parish, which, in case of fire, is taken from the workhouse by a pauper crew—frequently idiots and cripples—without any person competent to direct its operations. At a mid-day fatal fire in Camden-town, a few months before the above meeting took place, the parish engine was immediately sent for from St. Pancras workhouse, scarcely a quarter of a mile distant; more than half-an-hour elapsed before it arrived, and when, after the loss of much time, it was got to work, its performance excited the ridicule and execration of the spectators, and was made the subject of special complaint at the coroner's inquest, but without any beneficial result. Perhaps there is hardly another parish in the metropolis containing a larger amount of *uninsured* property than St. Pancras, for the protection of which no efficient provision is made. If the inhabitants, who have so much at stake, initiate no steps for its protection, how can they possibly expect the insurance companies to do so, who have so small an interest in the matter? The inhabitants of St. Pancras, with their usual cupidity, wish the insurance companies to provide such an efficient fire-engine establishment in that locality as will enable the housekeepers to save the greater part or the whole of their insurance money; the insurance companies are, however, very unlikely to adopt such a suicidal policy. There is no doubt that the mistaken view of these matters which so extensively pervades the public mind, is greatly encouraged by the fire-brigade assuming to be the universal and exclusive extinguishers of fires, a duty for which, especially in suburban districts, this force is wholly inadequate. Where a better understanding of these matters prevails, the

Digitized by Google

suburban parishes are adding to or improving their local fire establishments. This has been done in Shoreditch, Hackney, Marylebone, Camberwell, and Kensington; in the latter parish a novelty has been introduced in the shape of a voluntary fire-brigade on the American principle, consisting of nine young men, tradesmen's sons, of the locality, who hold themselves in readiness, night and day, to go out gratuitously to extinguish any fires in the neighbourhood; Mr. Dunford, the overseer of Kensington, being their superintendent. An excellent first-class fire-engine, built by Mr. Merryweather, of Long-Acre, with the dress and accoutrements of the men, were paid for by the vestry of the parish. Within a very few days of their formation, this corps was called into action, and acquitted themselves admirably. During the last five months of the year several occasions called for the exertions of the volunteers; several fires have been extinguished, and many thousand pounds worth of property have probably been saved by their prompt and indefatigable exertions. Although their attendance at fires is gratuitous, non-attendance when called subjects the volunteers to a fine, but no occasion has yet occurred for its infliction; on the contrary, they have ever shown themselves ready, zealous, cool, and courageous, and it is probable their excellent example may be followed in other suburban parishes—certainly with advantage. The parochial fire-establishment of Islington, which has remained unaltered for the last twenty years, is now under the consideration of the vestry, with a view to improvements, and placing it on a footing adequate to the vast increase of buildings and population in this wealthy and extensive parish. The past year has seen the last of the London firemen-watermen. In consequence of the increasing infirmities of Mr. Connorton, who has for so many years past been the foreman of the West of England firemen, that office have been compelled to pension him off, and to disband the corps. At Michaelmas last the West of England became subscribers to the London Fire-engine establishment, and the only *legal firemen* now existing in the metropolis are the parish-engine keepers, and the whole question of fire-protection demands the attention of the Legislature. "In fact," says a recent writer, "a committee of the Board of Works should grapple this question of life and death, and wholesale destruction of property by the most terrible of the elements, as a great whole; resolved to set it down on a broad and satisfactory basis, if they would merit the approval of their countrymen for a performance of more importance than even the defication of the Thames."

13 Angel Terrace, Islington,
February 19th, 1859.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

At an ordinary meeting, held March 8th, 1859; W. Fairbairn, F.R.S., &c., President, in the chair; a conversation having taken place respecting Sir W. Armstrong's new gun, Mr. Roberts stated that he had, very many years ago, constructed a rifled cannon for the purpose of firing elongated shot coated with lead. Dr. Smith considered that the great merit of the new gun consisted in the manner in which the internal tube of steel was enveloped with wrought iron. The difficult problem of forming a perfect compound structure had received solution in the hands of Sir W. Armstrong, while others had failed.

Dr. Joule read an extract from a letter he had some time ago received from Professor W. Thomson.—"I have had an apparatus for Atmospheric Electricity put up on the roof of my lecture room, and got a good trial of it yesterday, which proved most satisfactory. It consists of a hollow conductor supported by a glass rod attached to its own roof, with an internal atmosphere kept dry by sulphuric acid: the lower end of the glass rod is attached to the top of an iron bar, by which the hollow conductor is held about two feet above the inclined roof of the building. A can, open at the top, slides up and down on the iron bar which passes through a hole in the centre of its bottom, and, being supported by a tube with pulleys, &c., below, can easily be raised or lowered at pleasure. A wire attached to the insulated conductor passes through a wide hole in the bottom of the can, and is held by a suitable insulated support inside the building, so that it may be led away to an electrometer below. To make an observation, the wire is connected with the earth, while the can is up, and envelops the conductor—its position when the instrument is not in use. The earth connection is then broken, and the can is drawn down about eighteen inches. Immediately the electrometer shows a large effect (from five to fifteen degrees on my divided ring electrometer, in the state it chanced to be in, requiring more than one hundred degrees of torsion to bring it back to zero, in the few observations I made). When the surface of the earth is, as usual when the sky is cloudless, negative, the electrometer shows positive electricity. But when a negative cloud (natural, or of smoke) passes over, the indication is negative. The insulation is so good that the changes may be observed for a quarter of an hour or more, and when the can is put up the electrometer comes sensibly to zero again, showing scarcely any sensible change when the earth connection is made, before making a new start." Dr. Joule stated that he had recently witnessed experiments with Professor Thomson's new Atmospheric Electrometer, the merit of which consisted in its extreme sensitiveness, and the facility with which accurate observations could be made with it.

A paper was read by Mr. Richard Roberts, M. Inst. C.E., entitled "Proposed Improvements in Pharology."

After adverting to the remarkable fact that the great majority of wrecks and collisions occurred in the immediate vicinity of the beacons intended to guard against them, Mr. Roberts mentioned that amongst the numerous schemes propounded for the improvement of our present system of pharology, that of Mr. Herbert, of the Admiralty, who proposed to moor a series of floating lighthouses of great power of illumination, in a direct line up the centre of the English and other channels, appeared the most worthy of attention. He (Mr. Roberts) perfectly agreed with this suggestion, to which his attention had been first called by Mr. Murphy's paper, read in section G of the British Association, recently held at Leeds, when it at once occurred to him that the principle of gyration might be advantageously employed to neutralize the action which the wind and waves exert upon floating-light ships.

After briefly describing the principal features of the catoptric and dioptric systems, Mr. Roberts stated that the latter was inapplicable to floating beacons, owing to their great oscillation, and that they were therefore still furnished with 12 in. reflectors, whose power was comparatively small. He felt convinced, however, that the more fully the system of Mons. Fresnel became understood, the more certainly would it be preferred to the catoptric system, over which it possessed, among other advantages, that of producing about four times the amount of light as the effect of the combustion of the same quantity of oil.

It was, however, essential to the adoption of this system, that the light apparatus be kept upright and free from oscillation, to obtain which desideratum Mr. Roberts proposed entirely to change the form of the vessel, making that portion of it which was immersed hemispherical, and that which was above water the fustrum of an inverted cone, as he thought that this form would present less resistance to the wind and waves, where these were expected to act from every point. In certain situations, however, a double-pointed vessel might be advantageously used.

In the centre of this float Mr. Roberts proposed to build a tower (whose lower end should project through the bottom of the float to serve as a keel) carrying a lantern as in shore lighthouses, and containing the necessary accommodation for the light keepers, &c., and within this lantern he proposed to place a dioptric apparatus of the second power, whose light being placed forty-five feet above the water line, might be seen at a distance of nine miles. Immediately below the light apparatus he would place a fly wheel suitably mounted on gimbals, and driven through the medium of certain wheels and shafts by a small engine, which, with its boilers, would be placed on the third deck of the float, or this wheel might be caused to revolve at its proper speed by two relays, each of three men. The engines and steam might be used for a variety of purposes, as to sound bells or whistles, hoist coals aboard, prevent the adhesion of snow to the lantern, &c.

Mr. Roberts proposed to moor the float by three anchors, to each of which he would attach two heavy cables, passing through hawse pipes 120° from each other; the tension on these he would regulate by a suitable windlass, and he fully believed that by this system of mooring the float (which together with the tower he would construct of iron), and by causing the dioptric apparatus to rotate (about one hundred times per minute), the desired object would be attained.

A NEW PLOTTING SCALE FOR SURVEYING LAND.

After the meeting, at the Institution of Civil Engineers on Thursday last, Mr. J. G. Austin explained a "Double Off-set Plotting Scale," for the use of Civil Engineers, Land Surveyors, &c., The invention was described to consist in the projection of the line upon which the plotting was to be performed, at a distance from the edge of the scale, by means of the "station pointers," so as to admit the smallest off-set being plotted on either side of the scale. The instrument was readily affixed to the paper and board, by placing the "station pointers" upon the line to be plotted upon, keeping the scale in use always on the left hand, and the lower pointer exactly at the station from which the line proceeded. Then, by turning the milled-headed screws at each end, the instrument was fixed immoveably during the operation of plotting. Should the length of the line exceed the capacity of the scales, the distance plotted must be denoted on the map, the instrument released by reversing the screws, shifted forward, refixed, and the work continued; but should the line be shorter than the capacity of the scale, the position of the instrument could be determined by the zero line of the off-set scale, without the necessity of extending the line to the length of the instrument. The scales could be adapted to suit the operator, could be made of any material in customary use for such purposes, or the principle could be adapted to any existing scales. The off-set scale was intended to traverse between the edges of the lateral scales, and the distance upon the line was to be determined by the edge, and the off-sets plotted on either side of the zero line. The instrument was said to be simple in its use, to save much time in the operation of plotting the details of railway and general surveys, to insure accuracy and avoid the possibility of error from shifting, and as the surface to be plotted upon could be seen, it enabled the smallest off-set to be denoted on either side of the line, with greater ease and correctness than by the customary mode.

THE MERSEY STEAM FRIGATE.

The Mersey, 40, screw steam frigate, Captain H. Caldwell, C.B., went out of Portsmouth harbour at noon yesterday, to test her speed at the measured mile in Stoke's Bay. The results of the trial gave great satisfaction both to the contractors for the engines and the Government officials on board. There was not the slightest appearance of "priming of boilers" or "heated bearings" so common in first trials. This is all the more extraordinary, as the Mersey gives the highest return of indicative horse-power of any ship yet tried out of Portsmouth harbour. Her nominal power is 1,000 horse, but on the trial yesterday it was worked up to the enormous power of 4,000 horses. The average results of speed obtained in the four runs at the measured mile gave 13·290, or better than 13¼ knots; pressure of steam, 20; vacuum, 24; revolutions, *maximum*, 56, mean, 55¼; diameter of screw, 20; pitch of ditto, 29; immersion, 6 inches; force of wind, 1·0; direction of wind, N.W.; draught of water forward, 20 feet 8 inches; ditto aft, 22 feet 7 inches; coals on board, 850 tons; consumption of fuel at full speed, about 140 tons every 24 hours; thermometer in engine-room, 62·0; ditto, stoke-hole, 100·0; ditto, on decks, 52·0; length of stoke-hole, 68 feet 10 inches; breadth of ditto, 10 feet; number of fires, 32. The tops of the boilers are 3 feet under the load water line, and another important feature is that the engines are placed abaft the mainmast, which may in consequence be stepped in the keelson. Three auxiliary or "donkey" engines are fitted on board, two to supply the boilers, and the other as a steam fire-engine; this is fitted with a 4½ in. copper pipe from the ship's side, under the beams of the orlop deck, fore and aft, with seven 2½ in. pipe branches up through the lower and main decks, each branch with two nozzles to screw on lengths of hose, and four branches on to the upper deck, with the same means of screwing on hose lengths. In the event of a fire breaking out in any part of the ship, it is only to turn on the main cock at the ships' side, set the steam fire-engine to work, and any amount of water can be instantly conveyed to any part of the ship. In the event of a fire breaking out in the orlop, or lower decks of the ship during action, the engineer and his staff could at once deluge the part with water, and extinguish any fire without the necessity of ringing the fire bell, and calling the crew away from their guns, or creating the confusion and alarm which would ensue under existing regulations. Should any portion of the pipes be shot away, turn-cocks are fitted so as to turn the part injured off, and not impair the efficiency of the rest. To make the engine complete for the purposes it is intended for, it should have a small boiler fitted for its special service, and not have to draw upon the main boilers, as, in addition to its usefulness as a steam fire-engine, it also by an ingenious and simple contrivance hoists all the ashes up from below, pumps out bilge water, and draws water for washing decks. The

Digitized by Google

Mersey's armament consists of, on the upper deck, 12 8-inch pivot guns, 10 feet 6 inches long, throwing a solid shot of 68.5. Main deck, 28 10-inch guns, 9 feet 4 inches long, throwing hollow shot of 84lb. The total weight of the guns (without carriages) on the upper and main decks is 178 tons 3 qrs. 2 cwt. A broadside from her would give to an enemy in action 1,652lb. of iron. We understand that all steam-ships are in future to be fitted with steam fire-engines on the Mersey's plan.—*The Times* of yesterday.

ELECTRO-MAGNETISM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Cork, March 12, 1859.

GENTLEMEN,—I have to thank Mr. Blair for the valuable information which he has given in No. 9, in answer to my query. His idea of the cause of the increase of magnetic power is quite correct. In accordance with his suggestion I have made a few additional experiments, the results of which I send herewith. The cores used were of solid round bar iron, one inch in diameter, and the pieces applied were of bar of the same dimensions; the battery used was Callam's; cells of pint size; coil 5 inches in length; central aperture 1¼ in.; primary wire, four layers of bell wire size in one length; secondary coil, four layers of moderately fine wire.

With an 8-inch solid core inserted into the coil, and fixed as high above the hammer as sufficed to give power just enough to keep it in slow motion, I found that the application of any piece of iron, however small, to the top of the core appeared to produce an effect proportionate to its size, but taking the acceleration of the vibration as a test, it required a piece of about 2 inches to produce any *marked* effect; a piece of 8 inches gave quick vibrations, and every addition of length, up to 29 inches, produced additional acceleration. I did not try any piece beyond that length. The effect was the same when bundles of wire were substituted for the solid core and applied pieces. Contact was not necessary for the development of the effect. The approximation of the pieces to the core induced an increase of intensity, less of course than that produced by contact.

I next tested the lifting power of the cores, and obtained the following results:—

With one cell of the battery attached—

An 8-inch core sustained from its lower pole.....	4 lbs.
A 29-inch " " "	11 "

With two cells attached—

An 8-inch core sustained	9 "
" " with 8-inch bar applied at top	14½ "
" " with 29-inch " "	19 "
A 29-inch core sustained	25 "

In the latter case the magnetism was concentrated in the lower pole, the top pole had but very faint attractive power. I next replaced the 8-inch core in the coil, and attached four cells of the battery; with that addition of power the core sustained 21 lbs. So that by taking the length of the core we obtain (roughly) as much increase of magnetic power as we do by doubling the battery power. The next result was rather contradictory. Although the magnetic power of the core was so greatly increased by the additions made to its length, as shown both by its lifting power and by its increased effect on the hammer, still I could not detect any marked increase in the shock from the secondary coil, although such was perceptibly the case when four cells of the battery were used with the 8-inch core instead of two. This, however, I attribute to the small dimensions of the coil and its defective construction. Perhaps some of your readers who are in possession of better apparatus will test this. An increase of magnetic intensity in the core ought to produce a corresponding increase of power in the coil; and if it is found to do so, we have evidently a ready means of increasing the power of these machines by a very simple addition to the apparatus.

I am, Gentlemen, your obedient servant,

THOS. C. HAINES.

Law Case.

MIDLAND CIRCUIT, WARWICK.—March 23.

NISI PRIUS.—(Before the Lord Chief Justice CAMPBELL and a Special Jury.)

REGINA *v.* BOND.

Mr. Macaulay, Q.C., Mr. Serjeant Hayes, and Mr. Beasley appeared for the prosecution; Mr. O'Brien for the defence.

This was a prosecution instituted by the Master and Wardens of the Gunmaker's Company of London—under an Act of Parliament intituled an Act for Insuring the Due Proof of Gun-barrels in England—for counterfeiting proof marks. The Act requires that gun-barrels shall go through two distinct proofs by severe charges of gunpowder, and be marked with certain marks; after the first proof, which is made when the barrel is in a rough state, a mark is impressed, which is called "the provisional proof mark;" the second mark is made when the gun is finished, and is termed "the definitive proof mark."

Four gun-barrels were sent by the defendant to one Harris, at Birmingham, for the purpose of being worked up for him by Harris, and they were impressed with what appeared to be the provisional proof marks. Evidence was adduced which clearly showed that these marks were counterfeit, and that an offence against the above-mentioned Act had been committed.

The LORD CHIEF JUSTICE summed up the evidence, observing that the Act was a most salutary one, and

The jury returned a verdict of *Guilty*.

The prisoner was sentenced to two months' imprisonment.

NOTICES.

B. CLEVERTON.—Your somewhat lengthy letter shall receive due attention, and if, on careful perusal, it is deemed suitable for publication it shall appear.

J. C. WEST.—The proposal to discharge groups of cannon simultaneously by electricity was made long since.

CAPT. NORTON.—Too late for this number.

W. G. NORRIS.—Your letter is under consideration.

M. WOOD.—Mr. Walker's address is 17 Cowper-street, City-road, London. We are very much of your opinion respecting inventions for war purposes.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

LIST OF NEW BOOKS.

Our Weekly Gossip.

Sir William Armstrong—who is to be invited to a public dinner at Newcastle-upon-Tyne in the course of a few days—is about to provide a lecture-room for the Newcastle Literary and Philosophical Society. The expense thus generously borne by Sir William will exceed £1,200.

Printed forms have been delivered to the leading men and foremen of the Royal gun factories in Woolwich Arsenal, prohibiting, on pain of instant dismissal, any information to be given relative to the department, except to naval and military officers in Her Majesty's service.

The trial trip of the Mersey, the largest steam frigate in the British Navy, has proved a great success, as will be seen by the report copied from the *Times* of yesterday on another page. This immense vessel is of no less than 3,727 tons displacement, and with engines of 1,000 nominal horse-power, steams at the rate of more than 13 knots per hour.

The steamers which are appointed to run between Suez and Australia under the Peninsular and Oriental Company's new contract, are the Benares, the Salsette, the Malta, the Northam, the Emen, and the Columbian. The power of these vessels ranges from 300 to 520.

We learn from a correspondent at Havre, that the suit of Mr. H. D. P. Cunningham against M. Bronard, for an infringement of his patent for self-reefing top-sails (mentioned in a correspondent's letter at page 191 of our last number), has resulted in a decision entirely favourable to the English inventor. M. Bronard is able to appeal to a higher court if he please, but the grounds for an appeal are extremely slight and unpromising.

The committee appointed by the British Association, at their late meeting in Leeds, to inquire into and report upon the performances of steam vessels, had an interview with the First Lord of the Admiralty on Tuesday afternoon. The deputation consisted of Vice-Admiral Moorsom, Lord Clarence Paget, M.P., the Earl of Caithness, the Marquis of Stafford, M.P., Lord John Hay, M.P., the Hon. A. Ellis, M.P., Mr. John Scott Russell, F.R.S., Mr. J. E. M'Connell, Captain Egerton, R.N., Mr. W. Smith, and Mr. H. Wright.

We cannot resist the temptation to put on record here the following kindly sentences penned by an eminent professional contemporary—the *Builder*—in its last number, although modesty forbids us to appropriate all their praise:—"This excellent journal (the MECHANICS' MAGAZINE) has of late been issued in an enlarged form, as an illustrated newspaper, and with various other improvements in detail. There is not a more practical or useful scientific journal in existence than the 'MECHANICS' MAGAZINE.'"

Captain Fowke, R.E., has patented a peculiar arrangement of portable fire-engine capable of being easily transported either by manual labour or horse power, and forming a compact and powerful fire-engine, the ordinary wood or metal cistern hitherto employed being dispensed with, whereby the efficiency and lightness of the engine are greatly increased. The patentee connects the slings to the centre of the body of the pistons or plungers of the pumps, and fixes the pumps and gear of the fire engine directly on to a wrought-iron axle mounted on large running wheels.

Professor Tyndall states, says the *Critic*, that he has submitted india-rubber and gutta-percha covered wires to a test of extreme severity, and has found the insulating powers of both substances excellent. He does not know which of them is best, and has never made an experiment with either of them in which hydraulic pressure was applied.

A deputation from the International Association for obtaining a uniform decimal system of measures, weights, and coins, waited upon the Chancellor of the Exchequer on Saturday, the 19th inst., to oppose the introduction of a change which they characterise as "the scheme for the decimilization of the pound avoirdupois," and which, though at first proposed only in reference to Her Majesty's Customs, must, they considered, be regarded as "having an ultimate view to the substitution of a new method of weighing goods in all public and private transactions without exception." We have the memorial presented to the Chancellor before us, but have not space for it, in this Number at least.

The drainage of the seaport town of Sheerness is just now exciting much attention among its inhabitants. The circumstances of the case are peculiar, the town consisting of two separate portions lying at some distance apart, and all of them below the sea level. We have taken some pains to look into the several schemes proposed, and strangely enough find that the best of them, as we think, is put forth in the editorial columns of a local paper, called the *Sheerness Guardian*. In this paper the whole question is discussed with much ability and exemplary temper, the writer evidently being practically acquainted with the facts, and very competent to discuss the engineering question raised.

The coal-miners of the Barnsley district have adopted a petition to the House of Commons, in which they urge the desirability of an eight-hours' Bill; that the machinery for raising coals should only work nine hours; that children under 14 years of age employed in mines shall only work half time; that owners of collieries shall be obliged to provide instruction in schools for the remaining four hours; that the adoption of the safety cage and other desirable scientific appliances shall be rendered compulsory; that the apprenticeship system shall be introduced into mines; and that a widow's and orphan's funds shall be provided by a tax of 4d per ton on all coals sold. Really some of these suggestions seem reasonable and just.

In a paper read last week at the Society of Arts, Professor Leone Levi exposed many of the devices to which both British and foreign manufacturers of the baser sort resort in order to secure the business which honest and able men create. We quite agree with Professor Levi in believing that it is most essential to remove any difficulty that may exist in our criminal law, for the purpose of visiting with high penalties those who counterfeit, pirate, abuse, and forge the names, cyphers, and trade marks of others, thereby defrauding the injured parties, obtaining money under false pretences, and otherwise perpetrating an open public deception and fraud. And it is also necessary to obtain similar guarantees from foreign powers, so that the courts of all civilised nations shall be opened for the suppression of such practices, by whomsoever, and against whomsoever, committed.

Admiralty agents have recently visited the Clyde Dockyards for the purpose of making minute inquiries with respect to the available means of building ships and engines. Two launches of some importance took place on Saturday; the Shannon, from the yard of Messrs. R. Napier and Sons, at Govan, and the City of Newcastle, from the establishment of Messrs. Scott and Co., Cartsdyke. The Shannon has been constructed for the West India Mail Steam Packet Company, and is the heaviest steam-ship ever built on the Clyde. Her dimensions are as follows:—length over all, 342 feet; length of keel and forerake, 330 feet; length on load line, 327½ feet; breadth of beam, 44 feet; depth to spar deck, 35 feet; tonnage (builder's measurement), 3,092 tons. The Shannon will be propelled by two side-lever engines of 800-horse power collectively;

Digitized by Google

the cylinders are 96 inches in diameter, with 9 feet stroke; and the paddle-wheels will be fitted with feathering floats. The engines and boilers are completed at Lancefield Works, and the vessel is expected to be ready to take her station in the course of July. The City of Newcastle is intended for the navigation of the River Hunter, in New South Wales, and is to be fitted with oscillating engines of 150-horse power, by Messrs. Macnab and Co., Shaws Water Foundry. She is the fourth vessel turned out by these firms for the Hunter River New Steam Navigation Company.

The official (Admiralty) report of Messrs. Miller and Taplin on the merits of the plan proposed by Mr. C. W. Williams for consuming the smoke of bituminous coal when used in marine boilers, was delivered on Saturday. The reporters arrive at the conclusion that it is possible to consume the smoke arising from north country coal, by the use of Mr. Williams' apparatus, and by the modifications of it introduced by the Newcastle Steam Coal Association to some of the northern collieries, and now being introduced generally into the steam-tugs of the Tyne. In the experimental boiler, smoke was prevented when the firing was pushed to a greater extent than 30lbs. to the square foot of fire-grate; in one instance, the firing was for half-an-hour at the rate of 55½ lbs. to the square foot, with but very light smoke, and for the next hour at the rate of 40 lbs. to the square foot, without any smoke; and in another instance, when a steam jet was introduced to force the draught, the firing throughout the experiment was nearly 36 lbs. to the square foot, the jet being produced by 20 lbs. steam. The system of firing pursued was to charge each side of the two furnaces alternately, and to throw the coal on the front of the fires. When requisite, the incandescent fuel was pushed back at either side of the furnaces towards the fire-bridges, so that the gases arising from the fresh coals always passed over the hottest parts of the fire.

At the Cramlington West Hartley collieries, the Admiralty reporters mentioned above, inspected a modification of the apparatus of Mr. C. Wye Williams, consisting of a furnace frame fitted with two fire-doors, the hinges of which are so placed, that the doors open back to back, the upper part and sides of the door-frame being pierced with a number of holes, and the lower parts of the fire-doors having horizontal slits in them for the admission of air into the furnaces. The object of having two fire-doors on one frame, opening in the way described, is to cause the stoker to throw the coal to the sides of the furnace, instead of into the middle, and to force him to fire each side of the furnace alternately. This modification of Mr. Williams' plan was fitted to three boilers in constant work, and the prevention of smoke appeared to be almost perfect. At the Bedlington collieries the reporters saw another plan used with much success. The fire-doors here were double, but opened in the usual way; the dead plate of the furnace as well as the fire-doors had slits for the admission of air.

A paper from Mr. R. Hunt—a great authority on mining subjects—was read on Friday at the annual meeting of the Geological and Polytechnic Society of the West Riding on the mineral produce of Yorkshire. The amount added in 1857 to the national wealth by the mining and metallurgical industries of this great county was estimated as follows:—Lead, £173,250; pig iron, £1,013,142; iron pyrites, £1,572; coals, £2,168,800; stones, £105,374; total, £3,462,198.

"It is well known," says a correspondent, "that finely-powdered glass is a powerful *absorbent* of carbonic acid. Mr. J. Bruce Neil states that if the walls and ceilings, as well as the paper-hangings of our apartments are coated with a solution of water-glass, the carbonic acid is readily absorbed, and the temperature of the room reduced. A small quantity of chloride of zinc added to the solution, renders it a disinfectant-insorbent. Where gas is consumed, the same effects are evidenced in the absorption of the sulphuric acid. Paper-hangings so treated, in the event of a fire, are rendered, in a great measure, incombustible. This is evidently an improvement on the arsenical paper-hangings."

The same correspondent says:—"In the Zwintergarten Museum, in Dresden, about half a century since, was exhibited a *gun* (and probably the same is there now), which was capable of discharging itself 40 times successively, without intermission. Our gunmakers would do well to lose no time in paying the above museum a visit."

The following information, derived from the *Publisher's Circular*, is important. Messrs. Chambers announce a new Encyclopædia; "A Dictionary of Universal Knowledge for the People," on the basis of the latest edition of the German "Conversations Lexicon." The publication is first to appear in weekly numbers at 1½d., and is expected to form about seven volumes similar to the "Information for the People." The publishers state that the work has been in careful preparation for many years, that it will be abundantly illustrated with maps and engravings, be the cheapest and one of the most comprehensive encyclopædias ever published, and is, for the mean time, intended as the crowning contribution of the editors to cheap literature.—Messrs. Bradbury and Evans announce an important series of works to which they adapt their beautiful natural printing process; the prospectus includes the promise of four volumes on "British Sea-weeds," by W. G. Johnstone, with 220 nature-printed illustrations; of two volumes on "British Ferns," by Thomas Moore, F.L.S., reprinting the letter-press of the well-known folio work (some time out of print), with 110 new illustrations; and of one volume on "British Mosses," by Dr. Lawson, with 30 illustrations, to be followed by other works uniformly printed in large 8vo; some six volumes altogether may be expected during the present year.—Mr. Lovell Reeve has just disposed of his series of valuable popular "Natural Histories" to Messrs. Routledge and Co., who will in future publish them at a cheaper rate; the series numbers 24 volumes.

Our excellent contemporary, the *Photographic News* (which has most completely fulfilled the high expectations expressed by us on its first appearance), presents us with the following curious remarks on Micro-Photography:—Dr. Muller speaks of a micro-photograph which had been shown to him, which was scarcely perceptible to the naked eye but as a faint spot on the glass; but which, on being looked at through a microscope, was seen to be a full-length portrait of the Emperor Napoleon III., in a military costume. We have seen another which represented the well-known picture of the Queen and twelve naval officers in council; every feature of each individual being perfectly distinct on the application of a microscope of rather high magnifying power; although a threepenny-piece would have covered the entire photograph and something more. Mr. Alfred Reeves has recently forwarded to us a specimen of one of these minute pictures, which consists of a plate containing the portraits of the kings and queens of England since the time of the Conquest. Here, on a space not larger than the ¼th of an inch square, may be perceived a miniature "National Portrait Gallery" with a portrait of every king and queen surrounding her Majesty, who is properly made the centre figure of the interesting group. We have already referred on a previous occasion to some of the uses to which micro-photography might be put, but there are some others which we may briefly notice. Suppose, for example, that two portions of the same army are encamped at a distance of one or two miles apart, the communication being cut off by the enemy, or rendered almost impossible by the use of "arms of precision;" a very simple arrangement would enable the fullest written despatches to pass from one portion of this army to the other, without risk, and almost with the rapidity of electricity. The despatch is written, and a micro-photograph taken which reduces it within the limits of—if a long one—a square inch. This is placed inside one of the hollow conical bullets and the end closed with lead. The hoisting of a given signal would announce that a messenger was about to be despatched; and with the accuracy which distinguishes our improved rifles, a commander might have his despatches delivered with a speed and punctuality to which no post-office has yet attained. In the case of a beleaguered town, too, such a method of communication between its inhabitants and an army approaching to relieve it might be invaluable. It has not the drawback either of requiring men to have a special training for the purpose of carrying on these communications; all the manipulations necessary might be learnt in less than a week. Neither would there be any necessity for using a cypher, as there would be no risk of the despatch falling into the hands of the enemy, and hence there would be less chance of misapprehension of instructions than exists at present.

After the delivery of Major Rhodes' lecture on Tents on Monday evening last, at the weekly meeting of the United Service Institution, Mr. Andrew Smith stepped forward to read a paper on an electric gun, which was alleged to be capable of discharging sixty balls per minute with precision. We listened intently, but vainly, for a description of this curious instrument, and Captain Fishbourne, who presided, appealed as vainly to the speaker for something more than an unintelligible jumble of known and unknown words. We were favoured, however, with a picture or two of the improved weapon, but as these alone have in no way assisted our ignorance, we decline to engrave them for the confusion of our readers. We give the following extract or two from a printed paper handed to us at the meeting. They *may* make the whole matter clear to some minds, although we are, we confess, altogether incapable of precipitating a useful idea from them. "This gun," says Mr. Smith, "discharges with precision and effect, sixty shots per minute, without smoke and comparatively little noise; the propulsive force produced by the decomposition of water, causing a continuous discharge of the electric fluid, and the unequalled force of a thunderbolt. Lightning is a phenomenon presenting the appearance of a vivid flash of light or fire in the heavens. It is effected by electricity in its positive and negative relation between one cloud and another. . . . A flash of lightning may be defined as the electric fluid in a state of explosion; and when explosions do take place, its immensely expansive and vivid force is considered to be known: yet it is certainly but little understood. Indeed, the power is so gigantic that it is unearthly, and in its plenitude fitted only for the wielding by an Immortal. Nothing with which the territorial globe and its inhabitants are acquainted is so potent, so sudden, or so subtle. For ages past, this power has only subjected humanity both to alarm and wonder. It was believed to be a direct and occasional emanation from the Supreme Being. Mortals had no notion that the principal ingredient of those fearful and destructive flashes, which produced so wonderful and unearthly an effect, pervaded the whole creation, including their own system and person, as thoroughly, or indeed more so, than does the air we breathe. Its most potent application, however, viz., its explosion (in imitation of the lightning flash and thunderbolt) has been hitherto but lightly investigated. This very important feature of this wonderful power has been for many years Andrew Smith's aim to develop. Experimental analysis has shown, that a main, and indeed the essential ingredient in the process in the lightning flash is water; or rather its gases as decomposed by electricity, two in number, hydrogen and oxygen. This process, the lightning flash, Andrew Smith has found the means of effecting at will; and the immense power so produced he controls and directs. For its accomplishment the application of electric caloric, and of aqueous vapours, are the essentials. The principle may be summarily described as the generation of a gas of a most highly refined or sublimated quality, producing intensely elastic power, effected by the decomposition of water—after the manner of lightning itself. In the combination accomplishing this process, caloric, at a temperature effecting the fusion of electric metals, is one and a principal ingredient. One application of this potent element is to the projection of heavy missiles. Mr. Andrew Smith is able to do this with a power, rapidity, and accuracy, which has not been accomplished by gunpowder. The machinery consists of a gun or guns, made of wrought-iron of the soundest description, varied from those now in use only by some increase in length." There! the invention is now before our readers, and we shall be glad to learn that they understand it.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated November 16, 1858.

2576. W. B. Johnson, Manager, and J. Shepherd, Foreman, of Manchester. Improvements in machinery or apparatus for adjusting the permanent way of railways.

Dated January 19, 1859.

168. J. H. Johnson, of Lincoln's-inn-fields. Improvements in apparatus for making cigarettes. A communication from J. L. L. Daimé, of Paris.

Dated January 24, 1859.

222. H. Owen, of Portswood, Southampton. Improvements in stockings.

Dated February 10, 1859.

378. G. L. Stocks, of Poplar, Ship Chandler. Improvements in steering apparatuses.

Dated February 17, 1859.

448. C. Fay, of Manchester, Railway Carriage Builder. Improvements in apparatus for working railway breaks.

Dated February 24, 1859.

502. J. Holms, of Glasgow, Gentleman. Improvements in machinery or apparatus for propelling vessels, ships, and boats.

Dated February 25, 1859.

512. C. W. Siemens, of John-st., Adelphi. Improvements in electric telegraphs and apparatus, and in supports for electric telegraphic line wires. Partly a communication from W. Siemens.

Dated March 2, 1859.

548. J. Valda, of London. Improvements in studs and other like fastenings for dresses, belts, or other purposes.

550. R. H. Collyer, of Alpha-road, Doctor of Medicine. A process of preparing materials for the manufacture of paper, and a machine employed therein, which machine is applicable for crushing, grinding, bruising, and reducing various substances.

552. F. J. Jones, of Aldermanbury, Manufacturer. An improvement in buckles and clasps.

554. E. Roche, of Marseilles, Manufacturer. Improvements in the manufacture of paper suitable for forming

Digitized by Google

cigarettes and for other purposes, and also improvements in the manufacture of cigars.

556. W. E. Newton, of Chancery-lane. Improvements in the construction of barometers, or instruments to indicate pressure. A communication from A. Nobel, of Paris.

558. J. Kershaw, of Allerton, near Bradford, Overlooker. Improvements in means or apparatus employed in weaving.

560. H. Brown, of Galashiels, Selkirk, Woollen Manufacturer. Improvements in machinery for cutting and finishing the surfaces of woollen and other fabrics.

Dated March 3, 1859.

562. H. Kohn, of Berlin, Tailor. Improvements in articles of wearing apparel called coats.

563. J. Harrison, of Bermondsey, Builder. An improvement or improvements in the construction of rotating window-sashes.

564. T. Wilson, of Birmingham, Engineer. An improvement or improvements in breech-loading fire-arms.

565. A. W. Hale, of New Britain, United States. A new and improved machine for cutting or mincing meat, vegetables, &c.

566. J. D. Dougall, of Glasgow, Gun Maker. Improvements in fire-arms.

567. W. Jackson, of Colne, Lancaster, Shuttle-tongue Maker. Improvements in shuttles for looms.

568. W. Score, of Clapham-road, Chemist. Improvements in the manufacture of soap.

571. T. Cook, of Stowmarket, Carpenter. An apparatus for raising and lowering coffins and bodies, either for burial or disinterment.

Dated March 4, 1859.

573. C. F. Dennet, of Pall-mall, Gentleman. Improvements in bayonets.

574. M. Rider, of Todmorden, Mechanic. Improvements in, or applicable to, machines for preparing, spinning, and doubling cotton, and other fibrous materials.

575. J. Cowban and E. Andrews, of Burnley. Improvements in machinery or apparatus for spinning fibrous materials.

576. R. A. Brooman, of 166 Fleet-street, London, Editor of the MECHANICS' MAGAZINE and Patent Agent. An improvement in boiler stays. A communication from J. Perrier, of Nimes, France.

577. C. R. Mead, of Great Dover-st., Gas Engineer. Improvements in water gas-meters.

Dated March 5, 1859.

578. W. and J. Bailes, of Oxford-st. An improved ship's berth for prevention of sea-sickness, composed of wood and metal.

579. J. M. Dunlop, of Manchester, Engineer. Improvements in machinery or apparatus for cleaning fibrous materials.

580. J. Leigh, of Manchester, Surgeon. Improvements in the purification of coal gas.

581. J. Fraser, of Banff, Manager. Improvements in ploughs.

582. F. W. Parker, of Sheffield, Saw Maker. Improvements in sewing-machines.

583. E. Vigers, of Paddington, Gentleman. Improvements in the construction of ships and other vessels.

584. W. P. Savage, of Roxham, Norfolk. An improved machine for excavating, raising, and depositing soil.

585. F. Verdeil, Doctor, of Paris, and E. Michel, Chemist, of Puteaux, Seine. Improvements in treating madder.

586. G. Leach, of Leeds, Yarn Spinner. Improved machinery for reeling and leashing yarn or thread.

587. F. Morton, of Liverpool, Engineer. An improvement in the construction of strained fences.

Dated March 7, 1859.

589. H. W. Patrick, of Acton. An improvement or improvements in an apparatus for chemical and dental laboratories, or other manufacturing or experimental uses, which he proposes calling a "paragon laboratory forge."

590. D. Proudfoot, of Glasgow, Merchant. Improvements in Turkey-red dyeing.

591. A. Cabany, of Anzin, France, Engineer. A new system of quoins (wedges) for railways.

592. W. Palmer, of Long Eaton, Derby, Station Master. An improved railway carriage break, and coupling apparatus connected therewith.

593. F. Ayckbourn, of Vauxhall, Gentleman. Laminating indian-rubber cloths with paper sheets.

594. W. Gossage, of Widnes, Chemist. Improvements in the treatment of certain ores of copper for the extraction of metals therefrom.

595. J. Aspinall, of Great Tower-st., Civil Engineer. Improvements in evaporating in vacuo.

596. P. E. Aimont, of Paris, Civil Engineer. Improvements in the construction of waggons and other carriages for railways and ordinary roads, and of apparatuses connected therewith.

597. J. Orr, of Glasgow. Improvements in weaving ornamental fabrics.

598. J. P. Clarke, of Leicester. Improvements in the manufacture of reels for the winding on cotton, linen, thread, silk, or other fibrous materials.

599. J. L. Jullion and G. Pirie, of Aberdeen, Paper Makers. The manufacture of gelatine.

Dated March 8, 1859.

601. A. Booth and A. Booth, jun., of Manchester, Machine Makers. Improvements in machinery or apparatus for making or manufacturing tags for laces.

603. G. Twigg, of Birmingham, Manufacturer. An improved fusee-igniter for the use of smokers.

605. J. N. Ryder, of Bexley-heath. Improvements in preserving fruits, and in apparatus used for such purposes.

607. W. Clark, of Chancery-lane. Improvements in submarine telegraph cables. A communication from A. H. S. Treve, of Paris.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

628. N. Washburn, of Massachusetts. A new and useful or improved machine for rolling tyres for wheels. Dated March 11, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, March* 22, 1859.)

2491. J. Richmond, J. Quick, jun., and A. Fraser. Meter.
2502. E. E. Allen. Propellers.
2506. M. Henry. Fastenings. A communication.
2518. J. Corner. Screw rivets.
2528. J. Blethlyn. Fuel.
2536. A. Mickelthwate. Treating horn.
2542. G. T. Bousfield. Illustrating conic sections. A communication.
2548. J. Taylor. Steam engines.
2551. L. Petre. Ornamental with glass.
2555. A. B. Woodcock and J. M. Dunlop. Covering rollers, &c.
2556. D. Frodsham. Tubular steam boilers.
2557. M. Pullan. Drying yarns.
2558. J. A. Hopkinson. Steam boilers.
2564. W. G. Armstrong. Ordnance.
2568. J. G. Bunting. Horse-tamer.
2571. J. C. Boisneau. Horse-mill or gear.
2572. A. I. H. Parent. Buttons.
2575. C. J. C. Perry. Anti-collision dial.
2578. A. M. Bruère. Applying hydrogen gas.
2584. J. H. Tuck. Laying Telegraph cables.
2586. E. Welch. Tobacco.
2587. J. Robertson. Musical instruments.
2588. M. Scott. Breakwaters.
2591. J. Brennand. Ploughs.
2601. Sir C. T. Bright. Insulators.
2604. J. Leslie. Gas.
2615. J. Edwards. Trouser buttons.
2626. J. H. Johnson. Telegraph cables. A communication.
2630. T. S. Cressey. Casks.
2635. H. Ellis. Cultivating land.
2654. W. Ralston. Finishing fabrics.
2656. W. Gorman. Furnaces.
2662. R. H. Hughes. Lighting by gas.
2679. C. Parker. Looms.
2700. H. L. Pattinson. Utilizing the heat of slags.
2711. W. E. Newton. Steam-engines. A communication.
2730. A. E. C. Scheidel. Fastenings. A communication.
2751. L. Bissell. Trucks.
2761. M. Henry. Bone black. A communication.
2871. A. V. Newton. Bullets. A communication.
2959. J. Macpherson. Horns and hoofs.
91. W. and W. T. G. Bray. Locomotive engines.
448. C. Fay. Railway breaks.
463. S. Wheatcroft. Uniting lace to fabrics.
502. J. Holms. Propelling.
507. E. Price and E. Hawkins. Fish plates.
528. G. Horner. Hackling flax, &c.
549. J. M. Adams, D. Law, and J. Inglis. Fire-places.
566. J. D. Dougall. Fire arms.
580. J. Leigh. Coal gas.
581. J. Frazer. Ploughs.
589. H. W. Patrick. Laboratory forge.
590. D. Proudfoot. Turkey red dyeing.
596. P. E. Aimont. Waggons and carriages.
628. N. Washburn. Rolling tyres.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 18, 1859.

2106. J. Luis.
2108. J. B. Beasley.
2110. H. W. Grylls.
2114. H. Firmin.
2119. L. De Pariente.
2124. A. M. Perkins.
2130. R. A. Brooman.
2146. H. H. and W. F. Henson.
2150. G. L. Fuller.
2165. E. Thompson and W. Lazenby.
2172. G. T. Bousfield.
2210. M. Henry.
2246. E. Birchley.
2277. M. Sautter.
2298. W. E. Newton.
2553. M. L. J. Lavater.
2590. M. Caton.
2674. R. Bodmer.
3746. G. W. Bales.
2762. T. Bailey.
26. M. A. F. Mennons.
28. E. Balchin.
74. T. J. Claxton.
117. W. Wilson.
124. W. Craft & T. Wilson.
170. J. C. Reid and W. Milner.
188. J. Hick and W. Hargreaves.

Sealed March 22, 1859.

2129. T. Howe.
2140. D. Grant.
2145. R. A. Brooman.
2181. A. Normand.
2197. H. G. Collins.
2205. F. Trevithick.
2221. C. Hill.
2279. H. Parker.
2387. B. Goodfellow.
2455. D. Fryer, T. Leach, C. Watt, and W. Holmes.
2995. S. S. Bateson.
127. R. Romaine.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

630. H. Bessemer.
633. J. Mitchell.
640. P. A. De Fontainemoreau.
642. T. Bird and T. Rose.
657. E. S. Stott.
659. A. V. Newton.
666. J. W. Burton and G. Pye.
670. W. Drummond.
682. G. G. A. L. M. Schelhorn.
707. J. D. Dunnicliff and S. Bates.
711. W. Ball.
736. W. Ball.
790. F. Grice.

LIST OF SPECIFICATIONS, &c.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF DESIGNS FOR ARTICLES OF UTILITY REGISTERED.

Dates of Registration.	Nos. in Register.	Names and Addresses.	Subjects of Design.
1859.			
Feb. 9,	4150	W. and J. Sangster, Cheapside	Parasol.
,, 14,	4151	J. Whitehouse and Son, Birmingham	Bolt or fastener.
,, 28,	4152	W. Larke and Son, City	Slide cover.
Mch. 4,	4153	Oastler and Palmer, Bermondsey	Buckle.
,, 4,	4154	S. W. Silver and Co., Bishopsgate	Ventilator.
,, 8,	4155	Dawson and Macnicol, Glasgow	Shirt.
,, 9,	4156	G. Salter and Co., West Bromwich	Balance.
,, 10,	4157	Gray and Bailey, Birmingham	Roasting jack.
,, 16,	4158	C. Pullinger, Selsey	Rat-trap.
		PROVISIONAL REGISTRATIONS.	
Jan. 26,	1041	T. Williams, N. Wales	Washing mach.
,, 29,	1042	W. Eastlake, Plymouth	Portable stand.
Feb. 5,	1043	G. F. Meads, Old Kent-road	Advertising.
,, 7,	1044	J. Edwards, Lambeth	Mantle.
,, 10,	1045	R. Brailey, Fitzroy-sq.	Desk.
,, 14,	1046	J. Beddington, Birmingham	Clip.
,, 14,	1047	Mason and Richards, Birmingham	Knob or handle.
,, 16,	1048	T. Quinlan, Dalston	Folding map.
,, 21,	1049	F. W. Campin, Strand.	Gas-stove funnel.
,, 26,	1050	T. Archer, Cable-street	Advertising.
Mch. 1,	1051	J. P. Byrne, Dublin	Gun-stock.
,, 1,	1052	E. Webb, Lawrence Pountney-lane	Comforter.
,, 1,	1053	T. Hicken, Birmingham	Parasol joint.
,, 4,	1054	J. L. More, Dorking	Parasol.
,, 7,	1055	M. Frearson, Paddington	Candlestick.
,, 11,	1056	J. Brazier, Wolverhampton	Spring cramp.
,, 14,	1057	K. E. Morgan, Strood	Hooks and eyes.
,, 15,	1058	D. Brown, Lawrence-lane	Chess & draught board.
,, 17,	1059	R. Cayley, Bungay	Fumigator.
,, 17,	1060	H. J. and D. Nicoll, Regent-street	Gaiter.
,, 18,	1061	C. Watts, Harrow-road	Carriage pole.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1698, 1699, 1707, 1732.

BOILERS AND THEIR FURNACES, 1700, 1705, 1716, 1735, 1758, 1761, 1763.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1713.

SHIPS AND BOATS, including their fittings, 1730, 1748, 1770.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines. *None.*

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1717, 1718.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1704, 1714, 1725, 1729, 1738, 1745, 1747, 1750, 1760, 1765, 1766.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*

LIGHTING, HEATING, AND VENTILATING, 1703, 1727, 1735.

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1701, 1715, 1720, 1744, 1753, 1762, 1771.

METALS, including apparatus for their manufacture, 1706, 1721, 1754, 1764, 1767.

Digitized by Google

CHEMISTRY AND PHOTOGRAPHY, 1746.
ELECTRICAL APPARATUS, 1702, 1708, 1736, 1740, 1742.
WARFARE, *None.*
LETTER PRESS PRINTING &c., 1758.
MISCELLANEOUS, 1697, 1709, 1710, 1711, 1712, 1719, 1722, 1723, 1724, 1726, 1728, 1733, 1734, 1737, 1739, 1741, 1743, 1749, 1751, 1752, 1757, 1759, 1768, 1769.

1697. A. KELLERMANN. *The employ of new vegetable substances for dyeing, and especially to replace cochineal dye.* Dated July 28, 1858.

The vegetable substances used are the flowers and leaves of the elm (*ulmus*). The flowers produce a red and green colour, and the leaves a yellow colour. *Patent completed.*

1698. A. BOUGAULT. *An improved apparatus for purging or clearing steam engines of their condensed water.* Dated July 28, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1699. M. JOHNSON. *An improved rotary steam engine.* Dated July 28, 1858.

This consists in placing a wheel or revolving piston within a case, with journals for the axis of the revolving piston to work in or through, and which axis may be sufficiently long as to receive a fly-wheel (if necessary), also a cog-wheel or wheels, or other gearing for taking off and applying the motive power. *Patent abandoned.*

1700. R. HOWARTH. *Improvements in furnaces for steam boilers for the purpose of consuming smoke and economizing fuel.* Dated July 28, 1858.

This consists in so arranging the furnaces that the smoke from a fire to which fresh fuel has been applied is conveyed over a fire on which the fuel is in an incandescent state. This invention is particularly applicable to boilers having two fire-places and two flues. The end of each flue has a damper, and these dampers are raised and lowered alternately. When fresh fuel is applied to one fire the damper at the end of the corresponding flue is lowered to prevent the escape of the smoke into the chimney. The smoke from the fresh fuel is conveyed through a side passage between the two fire-places, or through a flue made near the firing doors over the other fire which is in an incandescent state; by this means the smoke is consumed and a saving in fuel effected. *Patent abandoned.*

1701. J. MANTON. *A new or improved candlestick.* Dated July 28, 1858.

This consists of a candlestick in which the candle is raised and lowered by a rack and pinion. *Patent abandoned.*

1702. W. A. GILBEE. *Improvements in the preparation of hydrated oxide of chromium.* (A communication.) Dated July 28, 1858.

This consists in preparing hydrated oxide of chromium on a large scale for painting and printing every kind of tissue, and for colouring paper. It is manufactured by two processes:—1. By heating on the sole plate of a reverbatory furnace, kept at a dull red heat, a mixture consisting of one part of bichromate of potass and three parts of refined boracic acid, moistened with water. This mass is thrown while red hot into cold water, and washed with boiling water to completely remove the borate of potass which has been formed. The improved hydrated oxide remains behind. 2. Replacing in the first preparation the bichromate of potass by chromate of soda. *Patent completed.*

1703. W. E. NEWTON. *Improvements in gas meters.* (A communication.) Dated July 28, 1858.

This consists, 1, in so constructing a measuring drum, which operates with an oscillating movement, that the water which seals the measuring chambers, and also the valve by which the direction of the gas is changed from one chamber to the other, are contained within the drum itself. 2. In providing such drum with a weighted lever properly applied to operate the valves by the oscillation of the drum. *Patent completed.*

1704. J. TAYLOR, J. LANG, and J. UTTLEY. *Improvements applicable to self-acting mules for spinning and doubling.* Dated July 28, 1858.

This applies to that class of self-acting mules, where a cam shaft is employed for effecting the changes in the working of the operating parts, when such cam shaft is rotated by a friction and contact pulley. The invention consists, 1, in arranging the friction pulley, so that it will, when acting upon the "contact pulley," be pressed against it by the force of a spring or weight. 2. In arranging the action of the friction pulley so as to dispense with the spaces formed in the periphery of the contact pulley. 3. In driving the friction pulley by gearing from the short intermediate or going-on shaft. *Patent abandoned.*

1705. H. HARDEN. *Improvements in the construction of tubular steam boilers.* Dated July 28, 1858.

This consists in constructing tubular steam boilers with iron tubes having brass ends, or ends formed of "homogeneous metal" or "homogeneous steel," secured to the iron part of the tube by brazing or otherwise, the ends of the tubes being those parts of the tubes secured in the tube plates. *Patent completed.*

1706. J. MILES. *Improvements in annealing pots used in the manufacture of iron, steel, and other metals.* Dated July 28, 1858.

This consists, 1, in making annealing pots with two open ends, and closing one end by a moveable lid. 2. In making stands for annealing pots with gauge pieces to resist the tendency of the pot to collapse. *Patent completed.*

1707. E. A. COWPER. *Improvements in generating power from steam, and in engines and apparatus for that purpose.* Dated July 28, 1858.

The inventor cools the cylinder and piston by a current of water so as to condense a sufficient quantity of the steam to keep the surfaces sufficiently cool to prevent abrasion; he is thus enabled to employ superheated steam of high temperature. He superheats the steam by passing it through pipes in a fire or flue. *Patent abandoned.*

1708. W. BUCKINGHAM, C. HUMFREY, and L. R. SYKES. *Improvements in the construction of telegraphic cables.* Dated July 28, 1858.

These consist in forming the rope which encloses the wires of silk and other fibrous materials, either alone or in combination with animal hair, and saturating such rope with gutta-percha. The inventors mix the gutta-percha when in the melted state with finely-powdered glass, silica, &c. *Patent abandoned.*

1709. J. CLIFF. *Improvements in the manufacture of soap.* Dated July 28, 1858.

The inventor makes soap from soap suds, scowerings, and other greasy waters. *Patent abandoned.*

1710. G. CAVAGGIA and A. SPINELLI. *Improvements in obtaining and applying motive power.* Dated July 29, 1858.

This consists in making the expansive force of gases evolved by the slow combustion of nitrates subservient as a motive power, or prime mover, for driving machinery. *Patent abandoned.*

1711. J. MUSGRAVE. *Improvements in stalls and enclosures for horses, cows, and pigs.* Dated July 29, 1858.

The specification of this invention is too lengthy to admit of an intelligible abstract in our pages. *Patent completed.*

1712. A. GALLARD. *A new system of trusses.* (A communication.) Dated July 29, 1858.

The inventor replaces the flat springs used in ordinary bandages with a small lever in the cushion; he replaces the cushions with stamped plates slightly stuffed; he adds a small band and a screw to regulate the pressure. *Patent abandoned.*

1713. G. S. PARKINSON. *An improved connecting apparatus for working railway brakes, and effecting a communication between railway guards and drivers.* Dated July 29, 1858.

This consists, 1, of a system of communicating power by tension to the brakes through two or more carriages, and in so arranging the apparatus that the slack which would be caused by the working of the buffer rods is obviated, and the extra tension which would be caused by the drawing out of the draw-rod is allowed for. 2, of a means of effecting a communication between the guards and drivers. The invention is not described apart from the drawings. *Patent completed.*

1714. J. BRIERLY. *Improvements in machinery or apparatus for spinning wool and other fibres.* Dated July 29, 1858.

This relates to spinning on the mule wool and other fibre carded or prepared by the condenser, and consists in causing the spindles of the mule not to rotate, or to rotate slowly, during a part or the whole length of the draught, or taking in of the length of the sliver required to be spun at each draw-out of the carriage, giving little or no twist to the said sliver during such taking in. *Patent completed.*

1715. J. L. HINKS. *Improvements in machines for cleaning knives, forks, spoons, and such other articles as are or may be cleaned by polishing, also in machines for sharpening knives.* Dated July 30, 1858.

The patentee describes a machine consisting of rotating brushes upon horizontal and parallel axes, driven by a winch. For sharpening knives he attaches to the foundation board a piece of leather covered with emery. *Patent completed.*

1716. J. F. W. FEATHERSTONHAUGH and F. WISE. *An improved self-acting apparatus for admitting water to steam boilers and indicating the water level.* Dated July 30, 1858.

The patentees use a float, which carries a rod passing through an opening in the top of the boiler, enclosed by a glass case placed on the boiler, through which the end of the rod is seen, and which is marked with divisions to indicate the level of the water. The float is also connected with a valve or tap communicating with the pump, the passages of the valve or tap being arranged so that when the water in the boiler is below the proper level communication with the pump is opened by the falling of the float. *Patent completed.*

1717. J. LUIS. *A machine for cutting up almonds for the use of confectioners and others.* (A communication.) Dated July 30, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1718. J. LUIS. *An apparatus for cooling beer and other liquids.* (A communication.) Dated July 30, 1858.

This apparatus is composed of two tubes, one in the other: one tube is pierced with holes, and conducts the liquid to the watering-pump, the other conducts air from a ventilator to precipitate the liquid into the receiver. *Patent abandoned.*

1719. J. LUIS. *A new system of infusion apparatus.* (A communication.) Dated July 30, 1858.

This consists, 1, of an infusion apparatus with two vessels, one above the other, with a filter-box in the second vessel and a water-level indicator; 2, of a similar apparatus with two filter-boxes; 3, of an apparatus with the two vessels standing side by side; 4, of a water-level indicator alone. *Patent abandoned.*

1720. G. W. REYNOLDS. *A new or improved cradle.* Dated July 30, 1858.

This consists of a cradle turning upon a horizontal axis or centres. Connected with the axis of the cradle is a coiled spring, which can be wound up by a key. The said spring is connected by a train of wheels and an escapement with the axis of the cradle, and when it is wished to rock the cradle the spring is wound up and the cradle set in motion. *Patent abandoned.*

1721. J. SPENCE. *An improvement in the manufacture of sheet, hoop, and nail-rod iron.* Dated July 30, 1858.

This consists in manufacturing such sheet, hoop, and nail-rods from puddled steel, or steel produced from pig-iron in the puddling furnace. *Patent abandoned.*

1722. J. WATKINS. *Improvements in machinery or apparatus for the manufacture of tallow and other candles.* Dated July 30, 1858.

Here the patentee employs an upright deal pillar, on both ends of which are screwed steel gudgeons, which work in sockets fixed in the flooring and ceiling. The pillar is perforated with six mortices, through which six beams are passed, and secured to the pillar by pins. On the ends of each beam are placed the frames for dipping the candles, each frame carrying twenty-five "broaches." The pillar is set in motion by the attendant, and the machine in its revolution will convey each frame of candles to and from the dipping mould. This dipping mould is so constructed that by the use of a lever or levers the wiping board passes over it, by which the ends of the candles are regularly wiped. *Patent completed.*

1723. C. and F. SCHIELE. *Certain improvements in "hydro-extractors," or centrifugal drying machines, and in the method of lubricating their bearings, which method is also applicable to other bearings where lubrication is required.* Dated July 30, 1858.

The patentees employ a wire-gauze chamber of a comparatively small diameter. They also employ an archimedian screw or worm inside this chamber, which in revolving turns the wire gauze by the friction of contact, and is so arranged that the wire-gauze chamber may be retarded somewhat by the feed of the material to be operated upon, or by a brake, so as to have a less number of revolutions than the worm, by which means the material (for instance, the sugar liquor) is propelled from one side to the other continuously. To obtain a continuous lubrication, they employ tooth or worm gearing to secure the turning of a wheel, which brings up the oil to the surfaces from a reservoir below. *Patent completed.*

1724. H. BESSEMER. *Improvements in the treatment of pit-coal, and in the separation of foreign matters therefrom.* Dated July 30, 1858.

This consists in separating pyrites, shale, carbonate of lime, &c., from pit-coal, by immersing the coal and its impurities in a fluid the specific gravity of which is greater than pure coal and less than the substances to be separated therefrom. *Patent completed.*

1725. T. WEBB and J. CRAIG. *Improvements applicable to spinning, doubling, winding, and warping yarns or threads.* Dated July 30, 1858.

This consists of spinning, doubling, winding, and warping upon tubes constructed of paper. *Patent completed.*

1726. J. DAVEY, H. SIMS, J. MAYNE, W. HODGE, and J. GERRANS. *An improved construction of valve, applicable to various descriptions of engines or machinery.* Dated July 30, 1858.

This relates particularly to the clack valve, and consists in making a circular groove in the cover of the valve. The groove is of a dovetailed form in section, and has placed in it a ring of wood, covered with leather, &c., which forms a tight joint. *Patent completed.*

1727. J. H. JOHNSON. *Improvements in candlesticks or holders for candles.* (A communication.) Dated July 30, 1858.

This consists in the use of a screw spindle having spiral threads formed upon it, such spindle being contained within the hollow of the candlestick. The upper end of the spindle carries a "save-all." *Patent abandoned.*

1728. N. S. DODGE. *Improvements in treating waste vucanized india-rubber.* (A communication.) Dated July 30, 1858.

The patentee claims—1, the method of treating waste vulcanized india-rubber with a view to its re-application to the manufacture of vulcanized india-rubber articles, by first disintegrating such waste and boiling the same in water until a soft plastic material is obtained; 2, the method of treating such waste with asphalte, coal-tare resin, pitch, shellac, &c. *Patent completed.*

1729. J. S. BAILEY. *Improvements in machinery for combing wool and other fibrous materials.* Dated July 31, 1858.

This relates to rotary machines, in which taking combs are mounted on a rotating comb-frame, and which combs take wool, &c., from a feeding apparatus, and transfer it to transfer-combs also carried by the rotating comb, which transfer-combs deliver it to a receiving comb. The rotating frame also carries carding frames, which have, simultaneously with the rotary motion of the comb-frame, a rotary motion on their own axis, which surfaces clean out the wool, &c., after it has been deposited on the receiving comb. The patentee dispenses with the transfer-combs, and mounts the card or other cleaning surfaces on another rotating frame. This frame revolves in such relation to the taking comb-frame that the cleaning surfaces transfer the wool from the taking comb to the receiving comb, and after it is deposited on the receiving comb take effect on the wool so as to clean it. *Patent completed.*

1730. H. DOUGLAS. *Improvements in freeing screw propellers from wreck or gear with which they may become entangled.* Dated July 31, 1858.

The inventor applies a sharp steel cutter, firmly fixed to the frame or other part in which the screw revolves, in such position that any rope, &c., that has hitched on the screw will be drawn by the rotation thereof underneath and along the edge of the fixed cutter. *Patent abandoned.*

1731. W. HARTLEY. *Improvements in the arrangement of slide-valves and side-pipes or valve-casings of steam engines.* Dated July 31, 1858.

This consists in so arranging the slide-valves and side-pipes, or valve-casings of steam engines, that the steam and exhaust-valves are worked independently of each other. *Patent completed.*

1732. W. C. S. PERCY. *Improvements in arrangements and mechanism or apparatus for the manufacture of bricks, tiles, pipes, and other articles made of plastic earths.* Dated July 31, 1858.

This consists of a variety of improvements arranged under fourteen separate heads, for an intelligible abstract of which we cannot give space. *Patent abandoned.*

1733. G. ASHCROFT and H. W. WOOD. *An improvement in hydraulic machinery.* Dated July 31, 1858.

Between an ordinary hydraulic pump, &c., the patentees introduce a vessel fitted with a piston working air-tight therein. To one side of this piston steam, air, or gas is admitted of the desired pressure, such pressure being exerted upon the water in that part of the vessel beneath the piston. The vessel is connected by a pipe to a hydraulic

Digitized by Google

press, &c.; and as water is forced into the vessel a constant and uniform pressure of the water therein may be maintained upon the ram or plunger. *Patent completed.*

1734. G. DAVIES. *Improvements in apparatus for planing electrotype and stereotype plates.* Dated July 31, 1858.

This consists in combining with the stationary cutter one or more horizontally rotating cutters, by which the plate is reduced to the required thickness, and its surfaces made true or parallel with each other by once passing beneath the cutters; and in certain springs and guides employed to keep the face of the plate in contact with the surface of the bed in which it is placed. *Patent completed.*

1735. J. HOUSTON. *Improvements in the means of effecting the consumption of smoke in furnaces.* Dated July 31, 1858.

This consists in preventing the smoke from ascending directly from the ordinary smoke-box by a damper or valve, which shuts in, when required, the lower part of the stack from the atmosphere. At or near the top of the smoke-box is a reverberatory tube or pipe, and just above the smoke-box a blow-pipe, which blow-pipe will cause the smoke to return to the burning fuel and be destroyed; that which passes into the smoke-box will pass through the reverberatory pipe into a chamber in which are jets of flame, which are intensified and directed by a blow-pipe, and this portion of the smoke will pass back into the smoke-box, and thus the whole will be consumed. *Patent completed.*

1736. H. CONYBEARE. *Improved apparatus and machinery for the laying of submarine telegraph cables.* Dated July 31, 1858.

This invention was described and illustrated at page 93, No. 6, of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

1737. H. CONYBEARE. *Improvements in apparatuses for generating and superheating steam, and for producing the condensation of steam.* Dated July 31, 1858.

This invention was described and illustrated at page 172, No. 11, of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

1738. G. T. BOUSFIELD. *Improvements in knitting machines.* (A communication.) Dated July 31, 1858.

Here when one of the feed-yarn breaks, instruments are brought into action which remove the corresponding presser from the beards of the needles, or which so change the position of the corresponding sinker that it no longer pushes the work from under the beards of the needles. The feed-yarn is passed through an eye formed in a rod, and when the feed-yarn breaks or fails this rod falls, and in so doing acts on a trigger, thus liberating a weighted arm which, in descending, withdraws a bolt and allows the presser to slide back in guides in which it is mounted. *Patent completed.*

1739. E. J. M. CETTI. *An improvement in barometers, gauges, and other analogous instruments.* Dated July 31, 1858.

This consists in making the glass tubes of the above instruments with the cistern and stop cock all in one piece. *Patent completed.*

1740. C. DE BERGUE. *Improvements in submarine telegraphic cables, and in machinery for paying out or laying down the same.* Dated July 31, 1858.

This invention was described and illustrated at page 157, No. 10, of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

1741. E. AGNENI. *Increasing particularly the effect of decorative pictures, landscapes, drawings, and prints.* Dated August 2, 1858.

Here the inventor engraves the outline of such paintings, drawings, &c., upon the quicksilver of looking glasses. He scratches out such reflecting apparatus and applies upon the cleared part of the looking-glass his artistic production. Likewise he applies at first the artistic subjects upon the single glasses, outlining the same afterwards with the reflecting substances. *Patent abandoned.*

1742. W. H. CRISPIN. *Improvements in the construction of electric telegraph cables.* Dated August 2, 1858.

Here the telegraphic wires receive an external coating of gutta percha, then another coating of the like material combined with hempen fibre, the whole being finally surrounded with an external covering of ordinary rope. *Patent abandoned.*

1743. G. S. HILL. *Improvements in hydro-pneumatic machinery.* Dated August 2, 1858.

This invention is based upon the principle that atmospheric air will sustain a column of water varying from 28 to 32 feet in height, as indicated by the barometer. The machinery consists of a water-wheel of about 28 feet in diameter, a cistern or well underneath it, and a tank 3 or 4 feet in depth fixed above the water-wheel. This tank has an aperture at the bottom fitting with a sliding hatch to open parallel with the buckets of the water-wheel for the water to flow through. There are to be fitted to this tank as many pumps as are requisite, according to the power required for pumping the water from the cistern or well below into the tank above, which pumps are to be driven by gearing from the water-wheel. The machinery is set in motion by opening the aperture at the bottom of the tank, when the water will rush through into the buckets of the wheel with considerable force due to the column of water in that tank, and thus give it a continual motion. *Patent completed.*

1744. J. W. SCHLESINGER. *A new or improved machine for roasting and basting articles of food.* Dated Aug. 2, 1858.

Here a spit revolves horizontally, and is driven by a spring movement acting through a train of wheels. The spit carries a set of arms, which, revolving with the spit, actuate upon a cam fixed on the inner end of a shaft turning at right angles to the spit, the outer end of which shaft carries a jointed lever standing out in a parallel line with the spit, and at the extreme end of this lever is attached a spoon which rises and lowers as the arms on the spit actuate upon the cam. The spoon brings up the fat for basting. *Patent completed.*

1745. R. R. JACKSON. *Certain improvements in machinery or apparatus for sizing yarn.* Dated Aug. 2, 1858.

This applies to sizing machines in which the yarn is conveyed on guide-rollers past a number of heated chests for drying the yarn, and consists in connecting these guide-rollers with the size-roller, and with the carrying or delivering-roller in the front of the machine; and in driving them either from a separate counter-shaft or from any shaft in the machine. *Patent abandoned.*

1746. G. DAVIES. *Improvements in the manufacture of bituminous mastics.* (A communication.) Dated Aug. 2, 1858.

This relates to the manufacture of bituminous mastics having the native asphalte of the West Indies for their base. These bituminous masties are composed chiefly of crude resin oil, native asphalte of the West Indies, and earthy or calcareous matters. *Patent abandoned.*

1747. S. HINE. *Certain improvements in machinery or apparatus for twisting, doubling, and retwisting and winding silk, or other similar fibrous material.* Dated Aug. 2, 1858.

This consists in the use of two bobbins (containing the single thread of silk, &c.), one on each side of the spindle or flyer; the threads to be twisted or doubled are brought from the bobbins over two separate pulleys, and thence over the ends of two small balanced levers, from which the two threads descend to the quill or bobbin upon the spindle, where they are doubled together in the usual manner. *Patent completed.*

1748. C. MORTIMER. *Improvements in apparatus for raising and lowering ships' boats.* (A communication.) Dated Aug. 2, 1858.

Here the lower blocks of the davit tackles have attached to each of them a metal ball which fits into a corresponding socket fixed to the boat, and these sockets are so placed that whilst the weight of the boat is on the tackles the balls remain firmly held by the sockets; but when the weight of the boat is taken off the tackles by the sea, the balls fall freely out of the sockets, and the boat goes free. *Patent abandoned.*

1749. W. B. B. HARVEY. *Improvements in fly or screw presses.* Dated Aug. 2, 1858.

Here the screws of such presses are connected with the piston of engines, which make partial rotations within the engines. *Patent completed.*

1750. J. L. NORTON. *Improvements in apparatus for drying wool and other substances.* Dated Aug. 2, 1858.

Here the wool, &c., is placed on an endless apron, which moves into and through an enclosed chamber. The apron is formed so as to allow of air passing through it freely, and through and amongst the wool, &c., placed thereon. *Patent completed.*

1751. E. and W. HEYWOOD. *Improvements in the construction of metallic pistons.* Dated Aug. 2, 1858.

This consists in a mode of applying springs to the wedges acting on the wearing rings of pistons to keep them in contact with the internal surface of the cylinder within which the piston works. The wearing rings are each made in two segments. A wedge is inserted between the ends of the segments at one side, and a centre pivot is applied between the other two ends. This pivot prevents the escape of steam into the body of the piston. The wedge is made with an internal projection, which is acted upon by a coiled spring; by this means a constant pressure is kept up on the wearing ring. *Patent abandoned.*

1752. H. GREAVES. *Improvements in constructing streets and roads, and thereby facilitating traffic, and providing for the more convenient conveyance of sewage, drainage, gas and water supplies, and telegraphic wires along the same.* Dated Aug. 2, 1858.

The patentee forms the foot pavement of open work plates or grids of cast iron, and leaves a space beneath, along which the pipes for gas and water may be laid. The curb is also of cast iron, in the form of a hollow surface channel, having openings along its sides for the water from the roadway and foot pavement, and communicating at intervals with tanks sunk to a lower level for receiving the solid matters. There are arrangements for a railway included. *Patent completed.*

1753. M. BILLING. *Improvements in metallic bedsteads and cots.* Dated Aug. 2, 1858.

This relates to the head, foot, and side rails. The inventor employs a tubular form of metallic frame or beading, having a longitudinal slot opening, corresponding in width to the thickness of the pannelling to be inserted therein, so that by twisting or corrugating the edges of the said pannelling the same may be securely held. *Patent abandoned.*

1754. W. TAYLOR. *An improvement in the manufacture of iron.* Dated Aug. 3, 1858.

This consists in causing a stream or streams of hydrogen gas to enter into molten crude iron while yet in the crucible of an iron-smelting furnace. *Patent completed.*

1755. G. DAVIES. *A process and apparatus for the extraction of oils for illumination and lubricating purposes, and of carburetted hydrogen gas from the native bitumen of the West Indies.* (A communication.) Dated Aug. 3, 1858.

Here the apparatus is similar to that employed in the manufacture of coal gas. *Patent abandoned.*

1756. T. GREENHALGH. *Improvements in apparatus applicable to steam boilers.* Dated Aug. 3, 1858.

This consists, 1, in an apparatus by which the supply of feed-water is regulated; 2, in an apparatus by which notice is given when the water of a steam-boiler descends below a certain level; 3, in an apparatus for allowing steam to escape when the pressure in the boiler exceeds the required limits, part of which forms a mercury safety valve. These apparatuses are not described apart from the drawings. *Patent completed.*

1757. J. SHAW. *A machine for the manufacture of pasteboard and cardboard.* Dated Aug. 3, 1858.

This consists in pressing together sheets of paper by means of rollers; the several sheets of paper being caused to adhere by a glutinous substance. *Patent abandoned.*

1758. R. CUNNINGHAM. *Improvements in the production of letter-press printing surfaces, and surfaces used in reproducing ornamental patterns or devices by printing or otherwise, and in the apparatus connected therewith.* Dated Aug. 3, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1759. J. STEEL. *Improvements in brewing and distilling.* Dated Aug. 3, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1760. G. BELL. *Improvements in embossing and printing dies, and in the manufacture of "lace," or perforated embossed paper.* Dated August 3, 1858.

The patentee claims—1, in constructing embossing and printing dies with a loose "centre" or "centres," or plugs having flanges or heels, which prevent the centre or centres from falling out when the die is inverted, but which allow them to be protruded by the action of a spring to a sufficient distance to admit of their being inked; 2, constructing embossing and printing dies with a loose or separate collar, and a loose or separate centre or centres, such collar being secured by screws in or upon a block containing a spring for protruding the centre or centres. Also constructing such dies with a projection or flange in the interior of the block, for preventing the escape of the die or plate which rests upon the spring. *Patent completed.*

1761. J. KINGSLEY. *Improvements in the construction of steam boilers.* Dated August 3, 1858.

Here the inventor proposes constructing boilers of wood of sufficient strength and thickness to be coated internally with a non-combustible and impervious substance. The furnace for heating the water is to be contained within the boilers. *Patent abandoned.*

1762. J. H. JOHNSON. *Improvements in inkstands.* (A communication.) Dated August 3, 1858.

The essential feature here is the use of a tubular piston or plunger, fitting air and fluid-tight into a corresponding well, formed in the bottom of the main receptacle for the ink and having a stopper at its upper end, which stopper fits air-tight into the neck of the inkstand, excludes external air from the main body of ink, and prevents evaporation. The object is to raise a small quantity of ink for use, into an expanded dripping cup at the upper end of the plunger. *Patent completed.*

1763. J. GREENWOOD. *Improvements in the construction of steam boilers and other apparatus for heating water or superheating steam, which improvements are also applicable when heating air.* Dated August 3, 1858.

Here the patentee forms the plates of the apparatus for heating water with deep undulations. *Patent completed.*

1764. A. V. NEWTON. *Improved machinery for forging nails and other articles.* (A communication.) Dated Aug. 3, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1765. C. DE JONGH. *Improvements in machinery for assorting and preparing for spinning silk and other fibrous substances.* Dated Aug. 3, 1858.

This relates principally to a previous patent of the patentee, dated May 21, 1856, and consists in dispensing with the use of certain bands used in combination with an endless apron for feeding the fibres to the travelling chains. Instead of these bands he proposes to carry the feeding apron further forward, and pass it round a roller of small diameter, which will admit of the apron being carried over the travelling holding surfaces to the point where it is required to deposit the fibres. *Patent completed.*

1766. C. CALLEBAUT. *Improvements in sewing machines.* Dated Aug. 4, 1858.

This is not described apart from the drawings. *Patent completed.*

1767. J. SPENCE. *An improved method of rolling sheets from puddled steel or steel iron.* Dated Aug. 4, 1858.

Here the inventor first anneals the bar, either by slow cooling from the rolls, or by a separate process. He rolls it until it requires to be doubled, and then passes it into a chamber and keeps the heat greatly below the welding point of steel. After doubling he passes the sheets but once or twice through the rolls. *Patent abandoned.*

1768. J. TAYLOR. *Pneumatic and hydraulic machines.* Dated Aug. 4, 1858.

This relates to the use of air or water for moving weights, and consists in constructing a machine for raising, lowering, hauling, or transporting weights with gearing, and applying oscillating or stationary cylinders, directly connected therewith and fitted with pistons and the usual apparatus for transmitting the motive power employed, and converting the alternate or reciprocating action into a continuous circular motion. *Patent completed.*

1769. J. J. RUSSELL. *Improvements in machinery for cutting and screwing the ends of tubes.* Dated Aug. 4, 1858.

Here each tube is introduced into and fixed in a hollow mandril which receives rotary and reversible motion by suitable gearing. That both ends of a tube may be acted upon without moving it from the mandril, there is on either side of the head stock a bed, or suitable guides, on each of which slides a carriage having a cutter, for cutting off a portion of the end of a tube, and also a die or screw tool for cutting a screw at the end of the tube. The end of the tube when being cut is supported by rollers. *Patent completed.*

1770. J. W. GILES. *An improvement in propelling vessels.* Dated Aug. 4, 1858.

Here the propeller is applied at or about the centre of gravity of the vessel, the shaft of the propeller being at an angle to the keel, and, by preference, at or about an angle of 45 deg. to the horizon. *Patent abandoned.*

1771. J. BADCOCK. *Improvements in apparatus to be applied to ladies' dresses and other articles of wearing apparel.* Dated Aug. 4, 1858.

This consists in combining an apparatus for looping up dresses with a petticoat, belt, or band, by attaching the looping-up apparatus to the upper edge of the petticoat, belt, or band, in place of to a separate belt or band as heretofore. *Patent abandoned.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, APRIL 1, 1859.

PATENTS FOR INSTRUMENTS AND MUNITIONS OF WAR.

With most indecent haste, to say the least, the law officers have pushed through the House of Commons the bad Bill against which we hastily protested in our last number; or it would probably be more correct to say that they have allowed it to be thus forced forward without taking the trouble even to read it. Last year they acted in this manner; for when pressed upon the subject they admitted that the International Patent Right Bill had actually passed through all its stages in the Lower House, and had gone up to the Lords, before they became at all acquainted with its nature. And yet that was a Bill which, if it had become law, would have virtually overthrown the whole of the existing patent laws! So bad was it that the Clerk of the House of Lords would not so much as lay it upon the table, but got it summarily condemned to the oblivion for which alone it was fit.

This year's Bill—for the Suppression of Patents relating to Instruments and Munitions of War—was introduced and read a first time on the 21st of March; on the 24th it was read a second time; on the 25th it was passed through committee; and on the 29th it was read a third time. Thus in one week it has been hurried through all its stages, and that a week in which the powers of the House have been most excessively taxed by the demands of a prolonged debate on a profound constitutional subject. Further, it has received most, if not all, of its readings at midnight, when a proper consideration of its provisions could not possibly take place. What its fate will be in the House of Lords remains to be seen; but that it will pass we can scarcely believe; for, in its present form, it contains not inherent weaknesses only, but absurd formal defects. For example, while the 10th clause runs, "It shall not be lawful for any person to take proceedings, by *scire facias* or otherwise, to repeal any letters patent for any invention in relation to which the said Secretary of State has certified as aforesaid," the marginal abstract of that clause reads, "No *scire facias* to be brought until final judgment in an action for infringement." The two are manifestly at direct variance with each other, instead of being identical.

But however disgraceful the passing of such a Bill through the House may be, we have to deal with deeper evils than those of verbal blundering. We believe the whole design and scope of the Act is bad. It is a measure which is alarmingly capable of being turned into an enormous engine of corruption. It will give the Secretary of State for War and his department a terrible power of doing wrong. It is absurd to speak of the matter as applicable to rare and exceptional inventions only. There are scores of inventions for improvements in instruments and munitions of war patented every year, and the Secretary for War may seal up any one or all of them, if he pleases, and if the inventors be willing. Now, is it right to give a Minister the power of dealing with scores of inventors annually—the power of accepting their inventions, paying for them with public money, and sealing up from the public eye all the information relating to them? On the other hand, is it right to put the inventor, even with his own extorted consent, so completely in the power of a Minister as this Act does? No provision is made for securing to the inventor his just recompense, by arbitration or otherwise. No security is given to the inventor by which he may be assured that if his invention is locked up he will be fairly rewarded for it. In fact, the Bill, if it does anything at all, puts both the public interests of the country and the personal interests of the inventor entirely at the disposal of the Minister for the time being. The effect of this will be to drive English inventors to foreign Governments with everything that is really valuable.

Now, is there anything in the proposed secret system to render these evils tolerable? We believe not. If Great Britain were a weak, defenceless State, liable to menace and open to attack, there might be some ground for attempting to keep its advances in the means of war secret, in order to give it a chance of temporarily augmenting its powers of resistance if assailed. A chance of this kind might be worth the evils which such a system would necessarily entail. But is it becoming in England to resort to a policy of this kind? Is it worth its while to submit to those concomitant evils? Is not, on the contrary, our best, and bravest, and most satisfactory policy that of attempting no concealment, and subjecting ourselves to no corruption, content at all moments to defend ourselves with weapons which all the world may see. We are beyond all question both the richest and the ablest people on the face of the earth, and no devices of secresy are needed in order to keep us in our proper position.

The system proposed by the Government Bill will never, we are firmly persuaded, work satisfactorily if attempted. Numerous cases which may readily occur to impede its operation suggest themselves to our minds. For example, directly the Government purchase and seal up a patent, numerous claimants for the whole or parts of the invention will, notwithstanding the attempt at secresy, spring up on all sides; and as some of these may be the proprietors of existing patents, it will be impossible either to satisfy them or to put them off with vague assurances. Again, supposing the Government give an inventor £10,000 for an invention, which they carefully seal up; what is to hinder any second person who may come to know what the invention is (by connivance with the first inventor or otherwise), from offering the same invention to the Government, and thus setting up a second claim for a like or any other amount? If the demand be refused, the threat of publicity or of communication with a foreign Government will be held out; if granted, the public will be defrauded. The like process may be repeated any number of times. Indeed, there is nothing whatever in the Act to prevent a man who has sold his invention to General Peel to-day from selling it by an agent to the Emperor Napoleon to-morrow, and to the Czar of Russia the next day. Of course he will put himself under covenants and agreements not to communicate it to others, and of course no honourable man would then communicate it; but there are others who would be quite capable of doing so; and in making laws we should put no premium upon roguery.

But, not to extend these remarks, we confidently state that, whatever opinions may be held as to the principle of the measure, its passage in its present form is viewed with apprehension by those who have excellent means of understanding its character. Several of the most eminent inventors of guns and projectiles have expressed themselves strongly against it, and it is our duty to protest in their name against its unseemly progress. With proper time for its consideration the measure might, perhaps, be made tolerable; but as it is, there is nothing to be said of it save by way of deprecating its further progress, for the present, at least.

THE LONDON MECHANICS' INSTITUTION—WHO FOUNDED IT?

Fame, although no more than a "flake of rainbow flying on the highest foam of men's deeds," is nevertheless about as great a thing as man can aspire to in this world, and a common instinct of justice makes us all desire that when a wreath of honour is to be bestowed the right head should be lifted up to receive it. Now, it is universally admitted that the establishment of the London Mechanics' Institution was the root of that great modern tree of knowledge, the fruits of which are the thousands of Mechanics' Institutes that now abound in the land. In confirmation of the fact we have the testimony of a meeting held on Monday last at Willis's Rooms, at which the Bishop of St. David's moved, Sir John Johnstone, M.P., seconded, and the audience unanimously resolved, "That the London Mechanics' Institution having been the first society of the kind instituted in England, *having called many hundreds of similar institutions into existence*, and having afforded instruction in science and the arts to more than 25,000 of its own members.....possesses a strong claim upon public support and sympathy." The claim of the Institution being thus admitted, the founder of it is, of course, deserving of immense credit, and has a just claim upon the regards of ourselves and posterity. Who, then, was the founder?

Two men, and two only, have been prominently put forward—not conjointly, but independently—as its founders, viz., the late Dr. Birkbeck and the late J. C. Robertson, our respected predecessor, who, in 1823, brought the Mechanics' Magazine into existence. Lord Brougham, also, has, it is true, sometimes been mentioned as the founder, but his claim is seldom urged, and his lordship himself insists upon preference being given to another. Were there any room for a valid doubt as to the actual founder we should decline to discuss the subject, notwithstanding our close and manifest connection with it. But we believe there is none. Let us look at the facts of the case.

In a letter from Lord Brougham, read at the meeting before referred to—a meeting held in aid of the fund for the purchase of the building occupied by the Institution—his lordship thus refers to the opposing claims put forward by the friends of Dr. Birkbeck and of Mr. Robertson respectively:—

> "Such a meeting as you announce," he says, "can never be held without bearing in grateful remembrance the founder of the Institution, and they who question Dr. Birkbeck's claims to this great distinction have only been able to state that others had some months before broached the idea of such a plan. But twenty or thirty years before, he had laid the foundations of all that has since been done by delivering a course of lectures to working men, so that the great step must be regarded as having been made by him at the beginning of the century, and not in 1823, when we both founded and endowed the London Institution."

Now, before we proceed with this discussion, we must beg the reader to observe precisely what it is we have to decide—viz., who founded the London Mechanics' Institution?—because Lord Brougham here confuses the matter most seriously. What is the "great step" to which he refers? If the paragraph means anything definite at all, it must imply (1), that Dr. Birkbeck's lectures to working men in Glasgow, in 1800-1, were the first notable step towards the education of mechanics; (2), that the editorial articles in the Mechanics' Magazine, in 1823, merely "broached the idea" of a mechanics' institution, and nothing more; and, (3), that "some months" after that article appeared Dr. Birkbeck—or he and Lord Brougham together, for his lordship says "we" at the end of his sentence—founded the Institution.

Digitized by Google

We deeply regret the necessity we feel under of pronouncing and proving this view of the facts wrong, and most unjust to the memory of Mr. Robertson. Lord Brougham is an aged and honourable man, with a reputation so great and so pure that we would not lightly breathe upon it; but the truth is better than any human reputation, and we need not shrink from the right in any man's behoof. To the facts.

In No. 7. of the MECHANICS' MAGAZINE, for Oct. 11, 1823, Mr. Robertson published an editorial article (prepared at his desire by Mr. Hodgskin, his assistant), in which the establishment of an Institution, to be called "The London Mechanics' Institute," was advocated, and in which he announced that he was then "employed in maturing a plan" for giving effect to his desires in this respect. He further invited correspondence upon the matter, and the article concluded by saying:—"If we should see, as the result of this invitation, a probability of succeeding in our object, WE *will then call a public meeting for the purpose of submitting our plan for such an Institute*, leaving it with the meeting to dispose of it as they may think fit." The next week's number of the Magazine showed that the invitation was warmly responded to, and among other letters, one from Dr. Birkbeck to the editor, Mr. Robertson, was published, in which the Doctor said:—"It will afford me the greatest pleasure *to give you* any information which you may require respecting the original mechanics' class in Glasgow, and every *assistance* within my power in the formation of the Mechanics' Institute of London." In his editorial remarks in this number, (No. 8, for Oct. 18, 1823), Mr. Robertson concluded by saying:—"Finding the proposition which we made" (the WE should be particularly observed throughout this passage), "thus spontaneously approved and encouraged to a degree exceeding our most sanguine expectations; having no longer the least doubt as to the probability of success, we shall in our next announce the time and place of a public meeting to take the whole matter into consideration." In the next number it was stated that the arrangements were too far from complete to admit of the announcement of the meeting in it; but in the following number (No. 10, for Nov. 1), the meeting was appointed for 11th Nov. On that day—precisely *one month* after the first article on the subject appeared in the MECHANICS' MAGAZINE—the meeting was held, Dr. Birkbeck taking the chair by invitation (beyond doubt at Mr. Robertson's suggestion), and Mr. Robertson himself bringing forward the resolutions which were carried, and conducting the responsible business of the evening. Lord Brougham—then plain Henry Brougham, of course—was not even present, although he wrote an encouraging letter, and sent a draft for £20 upon his bankers. All these facts can be perfectly verified by simple reference to the first volume of the MECHANICS' MAGAZINE.

We will neither degrade ourselves nor affront our readers by commenting with any kind of elaboration upon the circumstances thus set forth. In every sense in which it is possible for a single man to found an institution—except that of finding *all* the necessary funds—Mr. Robertson founded the London Mechanics' Institution. That he was nobly aided by Dr. Birkbeck and Lord Brougham we most emphatically affirm, as Mr. Robertson himself repeatedly affirmed with the utmost cordiality. But as far as the actual origination of the Institution is concerned, there was another man who did more than they—and that was Mr. Hodgskin, who drafted the first editorial article, and was intimately and earnestly associated with Mr. Robertson in the earliest stages of the undertaking, *before either Dr. Birkbeck or Lord Brougham spoke, wrote, or knew anything whatever about it.* This ground it is impossible for us to give up. If the founding of the Institution be set aside, and the lectures of Dr. Birkbeck in Glasgow, 23 years before, be deemed the source of Mechanics' Institutes everywhere, then, of course, Mr. Robertson's claim to distinction as their founder ceases—and with it, we must be permitted to say, the Bishop of St. David's resolution, and a great deal more that certain modern friends of the Institution are doing their best to keep in existence.

If Lord Brougham can explain away the facts we have stated, well; if not, it is, we respectfully submit, incumbent upon him to retract the statement made in that part of his letter which we have quoted. No man can blazon abroad errors of the kind into which he has there fallen without detriment to his reputation; and it will grieve us deeply to know that the honoured name of Brougham has not been wiped away from a statement which *seems*, at least, to be "splenetic, personal, base."

TENT ARCHITECTURE.

IN the midst of this age of invention a man has only to open his eyes and look straight before him occasionally, and he will discover, notwithstanding all our skill, that many of the most common objects of life are still of the rudest possible character, or, at the best, but little removed from it. Let us take, for example, the case of tent construction, or of "tent architecture," to use a more ambitious designation, and what do we find? This: that while we have been spending year after year, age after age, century after century, in discussing Classical, Gothic, Early English, Late English, Perpendicular, Flowing, Geometrical, Decorated, and a thousand other styles of architecture in brick and stone, for the mere gratification of priestly prepossessions and artistic fancies mainly, we have been crowding our armies into tents of so bad a construction that they will neither keep out the water, nor admit the air, nor hold their place in a gale, nor effect satisfactorily any other object for which they are designed. That we may not fall into any exaggeration on this important subject, we will notice particularly the facts brought forward in the very instructive paper by Major Rhodes, the conclusion of which appears on another page of this Number—a paper which has a peculiar value, inasmuch as it treats copiously of a subject respecting which literature has hitherto been almost silent.

Now, Major Rhodes tells us that the canvas of which our British army tents are made is often bad; that neither the canvas nor the tent ropes are waterproof, and they therefore absorb so much moisture that their weight is often increased one-third; that for the reason just stated, the canvas allows damp to penetrate it; that the alternate wetting and drying of these non-waterproof materials rots them rapidly; that the ground fastenings are insecure, and sometimes yield to the stress of stormy weather—in which they are, of course, most necessary; and that the construction of these tents is such that they cannot be properly ventilated, and hence the troops occupying them are subjected to fever, diarrhœa, dysentery, cholera, and other deadly diseases. The reader has but to turn over a leaf or two and read for himself of the defects which Major Rhodes so clearly describes, and so variously illustrates by facts which cannot be questioned.

Fortunately, the defects which Major Rhodes has investigated are not left uncorrected. Bringing the experience of camp life, both at home and in the Crimea, to bear upon the subject, the gallant officer has given us a simple remedy, or rather an improved set of tents embodying the several remedies deemed necessary. The useful and practical character of his improvements our readers will at once discern. They involve the use of nothing cumbrous or costly, but furnish the means of providing the soldier with a firm, light, dry, and well-ventilated tent, which no civilian will ever be found to grudge him, and which no military officer should withhold from him. Yet our military authorities do appear—judging from the last paragraph of the Major's lecture—very slow in giving the new tents a proper trial. We ask not why—nor will the reader. Can an English public department do any good thing well or quickly?

The Hanoverian Government have, however, already had the tents examined and reported upon, and in confirmation of the high opinion of them which we have expressed, we will quote from the report of Colonel Richers to Major and Adjutant-General von Tschnirchnitz upon the subject. Colonel Richers says there were brought him in the camp at Wülfingen, three of Major Rhodes' tents, with the commands of His Majesty the King to pitch them in the camp of the 2nd Regiment of Infantry, and to examine them as to their suitability and durability. In respect of all the tents he says:—

"The interior space is much increased (beyond that of the Hanoverian army tent) from top to bottom; the men can stand upright without difficulty (this is not the case, however, with the very low watch tent), and the middle area of the tents is not diminished by the pole. There is a very useful arrangement within these tents for placing the muskets and accoutrements of the men, which, hardly decreasing the interior space of the tent, affords much convenience to the soldier. . . . The soldiers can readily lay hold of their own arms and accoutrements, even in the dark, without the slightest confusion or delay. The covering of the tents is of double white canvas, sewed together. It is a manufacture of wool and hemp. During the weather we had at the camp of Wülfingen, the tents were much warmer in the cool of the night than our linen ones, and much cooler than the latter in the heat of the day. In this respect, Captain Rhodes' tents have a twofold advantage over the linen tents of the Government. The pitching and striking of these tents offer no difficulties. The non-commissioned officers and privates, under my orders, learned the way after once seeing a tent pitched by the armourers (*zeughaus-officianten*), sent me for that purpose. Eight men, after very moderate practice, can pitch an hospital tent in from ten to twelve minutes; and four men a field tent in five minutes; the same with a guard tent."

After these general observations, he proceeds to give more special details of each tent, expressing his strong sense of their value.

If soldiers be worth anything at all—if it be not altogether an indifferent matter whether they are carried off by fatal zymotic diseases or not—if thousands of Englishmen, trained by years of incessant practice to the arts of marching and fighting, be really worth a little care on the part of their plumed and jewelled commanders, we ask that this question of how best to build the soldier's home may not be set aside or slighted. Seven-tenths of the mortality in our infantry are caused by zymotic, chest, and tubercular diseases. Let us save them, if we can—for their money value to us, if from no nobler motive.

ROYAL NAVAL ENGINEERS.

BEFORE the Admiralty can hope to make the engineers of the Royal Navy, as a class, what they ought to be they must do two things: first, they must cease altogether to enter as naval engineers men of inferior education and character; and, secondly, they must so far improve the position of the naval engineer as to render it acceptable and agreeable to young men of a superior kind. Lightly as it may be thought of by certain Admiralty functionaries, a reform in both these

Digitized by Google

respects is of immense importance, even as a matter of economy. If it were possible to lay before their lordships the expense to which the country is put by the unnecessary deterioration of boilers and engines which often results from neglect and mismanagement, we should not, we think, require to urge important changes upon them week after week. But such an appeal to matters of fact ought not to be required. Let any man of sense and education acquaint himself with that untutored class from which assistant-engineers have of late years been taken, and then ask himself whether it can by any possibility be a prudent thing to commit costly and delicate machinery to hands like theirs.

Nor will it suffice to reply to these considerations by saying that better men are not to be had in sufficient numbers. That they are not is due only to the fact that such men very properly refuse to mix themselves with others in every respect their inferiors, or to enter the service at all until the invidious differences that separate engineers from other scientific officers are removed. Let us take, for example, the masters—a most exemplary and deserving class of officers, but a class who have no inherent superiorities to engineers, so far as we know. Now, in the first place, masters are allowed to have three years of the time which they serve as second-masters qualified for master to count for increase of full and half-pay and retirement allowances. Again, by Order of Council of 19th May, 1846, "Forty of the senior masters on the list have the option of receiving the retiring rank of commanders; the first twenty at 12s. 6d. per diem, and the rest at 10s. 6d. per diem. Their widows are allowed pensions of £60 a-year." Further, masters at sixty years of age, who are qualified for first-rates, and who have twenty years' service as masters, may retire with the rank of captain; the amount of their retirement pensions being paid according to the rate of half-pay which they have earned by service as masters. They are further allowed store allowance when in charge of stores, varying from 4s. to 2s. 1d. a-day, according to the rate of the ship; and they have likewise tuition money of £5 per annum for each young gentleman instructed in vessels not bearing a naval instructor. They have further means of increasing their ordinary pay by pilotage allowances, for taking the vessel to which they may be attached into various ports requiring a pilot. Finally, dockyard appointments are also open to these officers as master attendants and assistant-master attendants, on increased pay and allowances.

Now, in contrast with all this, we find that neither is the engineer's time served as assistant-engineer, or any part of it, allowed to count for chief-engineership; nor is he allowed retirement allowances; nor does his widow receive £60, but only £50, pension; nor has he any allowance on account of stores; nor does either tuition or pilotage money fall to his lot; nor has he any very promising prospect of a dockyard appointment. In all these respects the engineer is kept inferior to the master, although nominally placed on a level with him. And in making this comparison, there is another consideration which should not be lost sight of. The master, as is well known, acquires his professional knowledge in the service, while the engineer has to gain his before he can enter the navy at all. Now, this is a very important fact, and one which gives the engineer the first claim of the two upon the good offices of the Admiralty. Yet the engineer is, as we have shown, treated with marked indignity. He is so, indeed, in other ways beside those which we have mentioned. The utter want of cabin accommodation to which all but chief engineers are subjected, deters many qualified persons from entering the service. The art and the science of engineering are every day advancing, and unless men keep themselves acquainted with its progress, it is impossible for them to keep pace as they should with the improvements of the day. The naval engineer, more than any other man in the ship, should be a student; but how is it possible for him to study huddled up in an engineer's mess with the noise and distraction of half-a-dozen others pressing upon him? Another mark of indignity is to be observed in the fact that engineers are the only officers whose appointments are not given out to the reporters of the daily press in the lobby of Whitehall. All others, from the captain down to the clerk's assistant—nay even to your gunner, are most faithfully sent forth, the engineer of our steam navy being the only exception.

All that we ask for the engineer of the British navy, and more, has been done already by the Emperor Napoleon for the French engineer. In the French navy, the first-class engineer ranks with the captain of a line-of-battle ship; the second-class engineer with the captain of a frigate; the sub-engineer of the first and second classes, with the lieutenant of a line-of-battle ship; the sub-engineer of the third-class with the lieutenant of a frigate; and the engineer apprentice with the naval cadet. Surely, if France can thus give her scientific class due and unequivocal rank, there ought to be no insuperable obstacle in the way of that class obtaining its just recognition in this country. The Lords of the Admiralty have again, we are informed, declared themselves unable to entertain the claims which we have endeavoured to state as fairly as possible; but this should and shall in no way lessen our expectation of ultimate and even speedy success.

THE SHORTEST WAY TO AMERICA.

If travelling be, as has been said, "a fool's paradise," it is a paradise which many innocents delight in; and they all demand the means of moving over the greatest possible distances in the least possible time. We were conversing this week with a gentleman—certainly no fit candidate for the kind of paradise mentioned, but a very sensible and excellent man—who, no longer ago than January last, was doing daily duties at Bangkok, away in the remote kingdom of Siam, but who, since that time, has made a leisurely visit to Singapore, spent three days idle in Ceylon, as many more in Egypt, strolled a week away in Paris, warmed himself in the sun of London last week, shivered in the snow of London this, and in six or seven days from the time at which these lines appear, will sit cosily with his wife and babes at home in New York. If we go on travelling at this rate, and still demand shorter routes and swifter ships, shall we always, we are almost ready to ask, find one world large enough for us? Shall we not ere long be attempting to sail from planet to planet, and steam from star to star?

But, without stopping to consider such curious questions as these, it is to be remarked that the great gain in time which has been assured to travellers between England and America by the Lever line, or Galway route, ought if possible to be made permanent. That it can be, is very clearly established by a document before us, and to this we here propose to direct attention. It is a copy of the report lately made to the Admiralty by Captain Washington, R.N., Captain Vetch, R.E., and Mr. Barry Gibbons, C.E., on the capabilities and requirements of the Port and Harbour of Galway. The instructions of the Admiralty with regard to these gentlemen directed them to report on the following points:—1. Whether any part of the Bay of Galway is capable of being made a harbour of refuge, or whether the bay possesses such advantages as would render it eligible in any part as a harbour of refuge. 2. Whether from its position such advantages would invest it with claims as a packet station; and, 3. If so, what plan should be adopted to facilitate the landing and embarkation of passengers and goods, especially during the winter months. In accordance with these instructions, they took advantage of a short recess in the Refuge Harbours' inquiry, and proceeded to Galway on the 5th of October, and spent the following four days there, during which, in company with Captain Bedford, R.N., Admiralty Surveyor, who surveyed the bay and harbour of Galway in the year 1845, Mr. S. U. Roberts, C.E., county surveyor and resident engineer on the part of the Board of Public Works in Ireland, some of the Harbour Commissioners, the chief pilot, and the harbour-master of the port, they visited and examined the river Corrib, Lough Atalia, the docks, and the limestone quarries. They also embarked in a small steamer, placed at their disposal by the Harbour Commissioners, and steamed round the roadstead, visiting Mutton Island with its lighthouse, and the Margarita and Black Rock shoals, a short distance down the bay.

In the roadstead they singularly enough found the transatlantic steamer Pacific, just arrived after a voyage of less than six days from Newfoundland. Some colliers were lying near the steamer, waiting to complete her with coals, but, owing to a fresh breeze from the S.W., they were unable to go alongside; and heavy demurrage was being paid to the coal vessels, in addition to the extreme inconvenience caused to the steamer in not being able to prepare for her return voyage, for which all the berths were already taken.

In answer to the first question, the Commissioners report that Galway Bay is to a great extent a refuge harbour already formed by nature. Its approach from the ocean is well defined, it is easy of access, and free from outlying dangers. It has a width of twenty miles between the outer headlands which shelter the bay, while the magnificent natural breakwater of the Arran isles stretches across fourteen miles of the width, and arrests the force of the Atlantic swell, leaving on either side a navigable channel or sound about four miles in width, well defined by day, and admirably lighted by night. This bay is 25 miles in length, from the Arran isles to the town of Galway, and all within it is safe as far as concerns the main point of a refuge harbour, namely, the saving of life. Under Black Head, on the south side of the bay, a fleet of 19 sail of East Indiamen, in the year 1794, rode for several weeks while waiting convoy. In the event of a vessel being driven into the bay with loss of anchors and cables, or in a leaky state, as recently occurred to the Propeller steamer, she may be safely run upon the soft mud in New Harbour, at the head of the bay.

In respect to its claim as a packet station, the Commissioners sagaciously observe that the problem has been solved, and in a way such problems ought to be solved. The enterprise of the Lever Transatlantic Packet Company has demonstrated that Galway has such a claim. It is an established fact that large transatlantic steamers, carrying 300 passengers, have for months used Galway as a packet station, have performed their voyages with punctuality and safety, and on one occasion have made the passage from Newfoundland to Ireland in less than six days—the quickest passage on record.

Digitized by Google

As to the landing and embarkation of passengers and goods, especially during the winter months, they deal with the latter part of this subject first, and consider, first, a landing quay; second, security in the roadstead; and third safety of navigation. Not only for the accommodation, but for the security of passengers, it is absolutely necessary that some immediate steps be taken to provide for the want of a landing quay. At present the large steamers are compelled from their draught of water to anchor in the roadstead at a distance of nearly one mile from the town, and to land their passengers and goods in hookers, open boats, or a small steamer. This may be accomplished at high water, but towards low water the discomfort and risk are very great, and such as no passengers should be subjected to. Mr. Roberts, C.E., the resident engineer, has prepared a plan, by means of which such temporary accommodation may be obtained at a trifling outlay. For the safety and the convenient placing of large packet steamers, three pair of moorings are stated to be required in the roadstead: two pair for the arriving and dedeparting steamers, and a third for a coal depot. And, lastly, the safety of navigation in approaching the harbour absolutely requires, in the judgment of the Commissioners, that a large conspicuous buoy and a red light be added, at certain points pointed out by them, to the present lights and beacons at the expense of the Ballast Board of Dublin. If these three simple works—the landing quay, the moorings in the roadstead, and the light and buoys—were executed at once, sufficient would be done to provide for the now pressing wants of Galway as a packet harbour; and passengers and goods might then generally be landed and embarked without risk, and the steamers might be navigated with safety, and lie at moorings in the the roadstead with tolerable shelter and security.

Should, however, the experience of twelve months prove that permanent packet station at Galway is required for Ireland, or for the general advantage of the United Kingdom, and especially for the carrying of the mails (and the present number of passengers, the amount of correspondence,* and the shortness of the voyage would seem to warrant such a conclusion), a more comprehensive scheme would become necessary, and such a scheme should embrace a harbour for national purposes, that is, a station for coaling and repairing steamers in time of war, for assembling convoys, for the relief of troops, and other military communications with the British North American colonies—a want that, sooner or later, must be provided for somewhere on the west coast of Ireland. Being on the spot, the Commissioners felt it to be their duty to consider such an extended plan, and instructed Mr. Roberts, C.E., to have the necessary borings and examinations made that would be required to enable a decision to be arrived at on some of the designs that have been suggested. They give a general outline of these designs, showing their leading features, with an estimate of their probable cost. We are happy to find that their report is in all respects favourable to the capabilities of the place.

Here, then, is good ground for believing that the distance to America, measured by time, has been definitively shortened by several days. All opposition to the Galway line from persons interested in the southern and western ports of England will and must prove unavailing. The public interest, and—what is more exacting—the public convenience, demand that the new route shall be kept open, and it only remains for rival ports to bear their injury as best they can.

* It is stated in evidence that two-thirds of the whole correspondence with the United States consist of letters to and from Ireland.

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, MARCH 24.

HOUSE OF COMMONS.

PATENTS FOR INVENTIONS (MUNITIONS OF WAR).

The Bill was read a second time.

FRIDAY, MARCH 25.

HOUSE OF LORDS.

THE WESTMINSTER CLOCK.

Lord CAMPBELL said the clock in the tower was expected to have been long before this of great service to the public, and especially to the gentlemen attending Westminster-hall, but it was not yet at work, although it had been placed in the tower for some time. The clock had four dials, and he observed on passing the tower that day that the fingers on each dial pointed to different figures. He understood that during his absence on circuit the clock had been at work for half an hour.

The Earl of DERBY said Sir C. Barry had stated that the chamber would be ready for the reception of the clock in the course of a week or ten days, but that Mr. Denison still required some work to be done in the tower.

SOCIETY OF ARTS.

AT a meeting of the members of the above Society, held on Wednesday last, Mr. Fothergill Cooke in the chair, Mr. Alfred Varley read a paper "On the Practical Bearing of the Theory of Electricity in Submarine Telegraphy, the Electrical Difficulties in long Circuits, and the Conditions requisite in a Cable to insure rapid and certain Communication." Mr. Varley observed that the metallic core of a submarine cable should be composed of a conductor of the highest specific conducting capacity, that a decrease in the retardation which is caused by the induction that takes place in submarine circuits can only be obtained by increasing the thickness of the insulating material, but that it will be better to do this by enlarging the sectional area of the conductor as much as is practicable. In designing a cable there are many considerations besides those of its simple electrical qualifications which have to be entertained. The object to be obtained is the best result with the most economical investment of money. Are the proportions which were adopted in the Atlantic cable the best to insure this? The weight of the conducting coil in this cable is about 63 lbs. to the mile, the value of which, speaking roughly, would, I suppose, be about as many shillings; when served with gutta percha its value was raised to £40 per mile; the iron sheathing and getting the cable on board brought its value up to £100 per mile. In this cable, therefore, only four per cent., at the outside, was invested in the conductor upon which the transmission of the messages depended. If the views which I have brought forward are correct, a conductor of double the diameter would only produce half the amount of retarding force of one of half the size; such a conductor at the very outside would not cost more than £16 per mile; and the increased expenditure in serving such a conductor with gutta percha and giving it an iron sheathing would not, comparatively speaking, be very large. The expenses of the staff and the hire of ships would be about the same in both cases. The latter would be, perhaps, increased slightly, but not to any material amount. The paper, which was unusually long, was received at its conclusion with demonstrations of applause by a numerous audience, among whom were noticed Professors Walker, Tyndall, and Hughes.

INSTITUTION OF ENGINEERS IN SCOTLAND.

AT a meeting of this Society, on Wednesday evening, Robert Stephenson, Esq., M.P., and Prof. R. Clausius (of Zurich), were unanimously elected honorary members.

Mr. Hunt, the Secretary, introduced for discussion the subject of

PATENT LAW REFORM.

After glancing at the existing patent laws, Mr. Hunt said the reduction in the fees on patents in 1852 opened the door to a great number of perfectly worthless inventions, but perhaps the worst evil consisted in the patenting (or in most cases the merely provisionally protecting) of numerous really valuable inventions by parties not in positions to work out their ideas to practical and useful results. An evil arising from the great number of patents was the difficulty of ascertaining what was and what was not patented. It was extremely fortunate that when in 185- patents increased so enormously, steps were at the same time taken by the Government to mitigate this evil by printing and distributing the specifications. Notwithstanding this, the evil referred to must necessarily continually increase, and a further reduction of taxes must notably enlarge the rate of such increase. The reduction of patent taxes would doubtless be a boon to inventors and to the public, but the value of the boon would be considerably enhanced if a measure could at the same time be devised which would have the effect of reducing the number of patents for valueless and abortive inventions. It was suggested that with the view of remedying existing evils, any new patent act should contain clauses to the effect that:—1. Any publication of an invention by the inventor, for, say six months before the patent is applied for should not invalidate it. 2. The actual use during that period by another party not authorised by the patentee should invalidate the patent. 3. The publication during that period of a description of the invention should not affect the patent, excepting in so far as it might bear upon the patentee's claim to be an original inventor. This measure would certainly reduce the number of patents; but the cases in which it would cause the public to loose valuable inventions would be few or none. On the other hand, many of the valueless patents would be replaced by patents for valuable inventions, which did not get patented under the existing state of things. It was well known that many valuable inventions never had been patented—they had arisen in the ordinary course of business, and various circumstances had prevented their being patented, such as want of funds or want of faith. In a few months these inventions had proved themselves worthy of a better fate; but having been published, valid patents could not then be got for them. The writer believed there were more cases of this kind than was generally supposed. The proposed measure would extend protection to all future cases of the same kind. The Secretary's remarks concluded with a few observations respecting the Manchester proposals.

After remarks from various members, it was resolved that the Council of the Institution should consider the question, and call a special meeting, at which manufacturers and others interested should be invited to attend.

A paper was then read "On the effect of a third cylinder in the Clyde screw engine," by Mr. J. G. Lawrie, which was followed by a discussion.

Mr. D. MORE exhibited and described a combined engine-counter and clock, devised by Mr. A. Mitchell.

Mr. WALTER NEILSON presented a valuable model of one of the finest of the American river steamers, in the name of Messrs. Ross & Winans, of New York.

Mr. J. M. ROWAN exhibited a model of his improved marine engines and boilers.

RAPID MONEY-MAKING AT THE MINT.

WE learn that the mechanical resources of the Mint, although exerted to an unprecedented extent lately, are found quite inadequate to supply the constant demand for money made upon that establishment; and that, consequently, an addition to the motive power employed there is being made. A new steam-engine of 40-horse power is in course of erection, and this is intended to drive the laminating machinery. Since the year 1810, when the first coin was struck in the existing Mint, an engine of 30-horse power, supplied by Boulton and Watt, gave motion to this branch of the coining machinery; but, as has been said, the pressure for money is now so great that this very creditable specimen of early engineering is not equal to the task imposed upon it. The new engine was contracted for by Messrs. Hall, of Dartford, and is on the combined high and low-pressure principle. It will be placed side by side with its ancient predecessor, which will not as yet be removed. The united power of the steam-engines employed in the cash department is 66-horses, reckoning that of the new money-maker.

An extension of time is aimed at for the completion of the Tyne piers. The preamble of a Bill promoted by the Commissioners for this object has been declared proved by a Committee of the House of Commons; and the Bill has been so modified as to enable the Commissioners to accept the proposed Government grant for a harbour of refuge (£250,000).

THE THEORY OF NAVAL ARCHITECTURE.

No. VI.

Let $y^6 = 24^7 . x$ be the equation to the curve $P_7 P_1 N_1$, represented in figure 13, (next column) in which $P_7 N_1$ and a line at right angles to it through P_7, are the co-ordinate axes. This figure may be regarded, like that of the previous example (p. 168), as a half midship section, approximating to the form of the midship section of a vessel of burthen. The breadth of the ship would be 48 feet to the outside of the planking; and the draught of water from the load line $P_1 N_1$ to the lower edge of the rabbet of the keel, 24 feet. Let, as before, the depth $P_7 N_1$ be divided into six equal parts, each being equal to four feet; and let a_1, a_2, a_3, a_4, a_5, a_6, and a_7, be the ordinates drawn through the points of division. From the equation to the curve, putting x equal to 24, 20, 16, 12, 8, 4, and 0 respectively, we have $a_1 = 24{\cdot}000$; $a_2 = 23{\cdot}460$; $a_3 = 22{\cdot}814$; $a_4 = 22{\cdot}008$; $a_5 = 20{\cdot}920$; $a_6 = 19{\cdot}184$; and $a_7 = 0$; applying the second Rule, and putting it in a form convenient for calculation,

Ordinates.		*Multipliers.*	
a_1 =	24·000	1 =	24·000
a_2 =	23·460	4 =	93·840
a_3 =	22·814	2 =	45·628
a_4 =	22·008	4 =	88·032
a_5 =	20·920	2 =	41·840
a_6 =	19·184	4 =	76·736
a_7 =	0·0	1 =	0·0
			370·076
(4 = common interval)			4
			3)1480·304
		Approximation =	493·435

It can be readily proved that the exact area of the figure we have taken as an example is equal to

$$\frac{8}{9} \times P_1 N_1 \times P_7 N_1 = \frac{8}{9} \times 24^2 = 8 \times 64 = 512.$$

The above approximation is therefore very far from the exact area, the error being 512 — 493·435 = 18·565, or above 3½ per cent.

Applying Rule 3, and putting it in form for calculation,

Ordinates.		*Multipliers.*	
24·000	×	1	= 24·000
23·460	×	3	= 70·380
22·814	×	3	= 68·442
22·008	×	2	= 44·016
20·920	×	3	= 62·760
19·184	×	3	= 57·552
0·00	×	1	0·0
			327·150
$\left(\frac{3}{8} \times 4 = \frac{3}{2}\right)$			3
			2)981·450
		Approximation	490·725

This method does not give a result so near the true area as the second Rule.

Applying the Rule, already given in the Table, for seven ordinates, which gives the approximating area when a continuous parabolic curve is made to pass through the extremities of the seven ordinates, we have

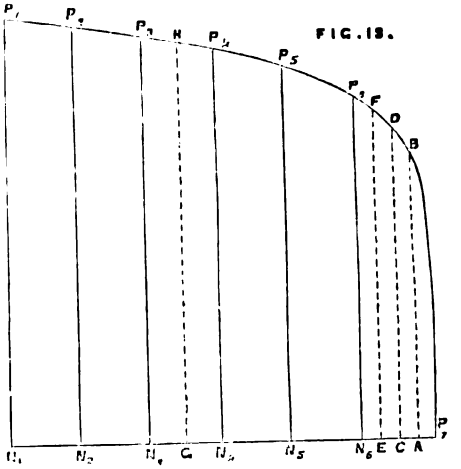
First and last Ordinates.	*2nd and 6th Ordinates.*	*3rd and 5th Ordinates.*	*4th Ordinate.*
24·000	23·460	22·814	22·008
0·0	19·184	20·920	272
24·000	42·644	43·734	44016
41	216	27	154056
			44016
24000	255864	306138	
96000	42644	87468	5986·176
984·000	85288	1180·818	
9211·104	9211·104		
1180·818			
5986·176			
7)17362·098		$\left(\frac{m}{140} = \frac{4}{140} = \frac{1}{35}\right)$	
5)2480·2997			
496·0599	Approximation.		
512·00	True area.		
15·94	Error.		

This Rule gives a result, in the present case, a little nearer the exact area than either the second or third Rules; but the error is still above 3 per cent—much too great to be disregarded by the naval architect.

We stated, when approximating to the area of a quadrant, that the errors mainly arose from the deviation of the approximating curve from the given curve in the neighbourhood of P_7, the two curves in their other parts being nearly coincident; the same is true in this case also.

From an inspection of Fig. 13, which is drawn to scale, we perceive that the direction of the curve at the extremities of the equidistant ordinates deviates tolerably evenly from P_1 to P_6, but from P_6 to P_7 the direction alters very rapidly. In the part, therefore, between P_6 and P_7 especially, the ordinates should be placed near to each other. For example, let $N_6 P_7$ be divided into four equal parts, each being equal to one foot; and at the points of division let the ordinates AB, CD, and EF be drawn parallel to $P_1 N_1$; these three, together with $P_6 N_6$ and P_7, make five equidistant ordinates, to which the second Rule may be applied to find the approximate area.

FIG. 13.



Again, let $N_1 N_6$ be divided into two equal parts, each being equal to 10 feet; and at the point of division let $G\,H$ be drawn parallel to $P_1 N_1$; then $P_1 N_1$, $G\,H$, and $P_6 N_6$ are three equidistant ordinates, to which the second Rule may also be applied.

From the equation to the curve we have, putting x equal to 1, 2, 3, and 14 respectively,

$$\begin{aligned} AB &= 16{\cdot}132; \\ CD &= 17{\cdot}592; \\ EF &= 18{\cdot}507; \\ G\,H &= 22{\cdot}437. \end{aligned}$$

The area of the part between $P_1 N_1$ and $P_6 N_6$, since the common interval is 10 feet, is equal to

$$\frac{10}{3}\left\{P_1 N_1 + 4 . G\,H + P_6 N_6\right\}$$
$$= \frac{10}{3}\left\{24{\cdot}000 + 4(22{\cdot}437) + 19{\cdot}184\right\};$$

And, since the common interval is one foot, the area of the part between P_7 and $P_6 N_6$

$$= \frac{1}{3}\left\{P_6 N_6 + 4\,(AB + EF) + 2 \cdot CD + P_7\right\}$$
$$= \frac{1}{3}\left\{19{\cdot}184 + 4\,(16{\cdot}132 + 18{\cdot}507) + 2\,(17{\cdot}592) + 0\right\}$$
$$= \frac{10}{3}\left\{\frac{19{\cdot}184}{10} + {\cdot}4\,(16{\cdot}132 + 18{\cdot}507) + {\cdot}2\,(17{\cdot}392) + 0\right\}.$$

The whole area of the figure, or the sum of these two areas,

$$= \frac{10}{3}\left\{24\,000 + 4(22{\cdot}437) + 1{\cdot}1(19{\cdot}184) + {\cdot}4\,(16{\cdot}132 + 18{\cdot}507) + {\cdot}2\,(17{\cdot}592) + 0\right\}.$$

Putting it in a form convenient for calculation,

24·000	×	1	= 24·000
22·437	×	4	= 89·748
19·184	×	1·1	= 21·1024
18·507	×	·4	= 7·4028
17·592	×	·2	= 3·5184
16·132	×	·4	= 6·4528
0	×	·1	— 0·0
			152·2244
			10
			3)1522·244
			507·415 Approximation.
			512· True area.
			4·585 Difference.

The error here does not amount to one per cent., and we have only taken the same number of ordinates (seven) as in the other methods of approximation, but have placed them differently. These examples show very clearly that by placing the ordinates with a due regard to the curvature, and applying the second or third Rules, a very close approximation to the true area will be obtained, with a small amount of labour in the calculations.

Digitized by Google

We should, however, strongly recommend the student to apply, in other examples, the rules before given in a table, for finding the approximate area when a continuous parabolic curve passes through the extremities of the ordinates; and they will find that the second or third Rules applied to the same cases, in the manner already pointed out, will give more accurate results, with much less labour in making the calculations.

The figures to which the rules may be applied, and their exact areas, and ordinates readily obtained are ellipses and parabolas. The ellipse is a figure too well known to require us to indicate the method of obtaining the lengths of the ordinates, and the exact area. The family of parabolas is perhaps not so generally known. The equation to the parabola from the vertex is $y^n = p^{n-1} . x$, in which p (the parameter) is constant in the same parabola, and in the example above given was equal to 24; giving x different values in this equation, the values of y, the corresponding ordinates, can be obtained.

The exact area corresponding to any length of axis, X—where Y is the ordinate drawn at the distance X from the vertex—is

$$\frac{n}{n+1} \cdot \left(Y \cdot X \right).$$

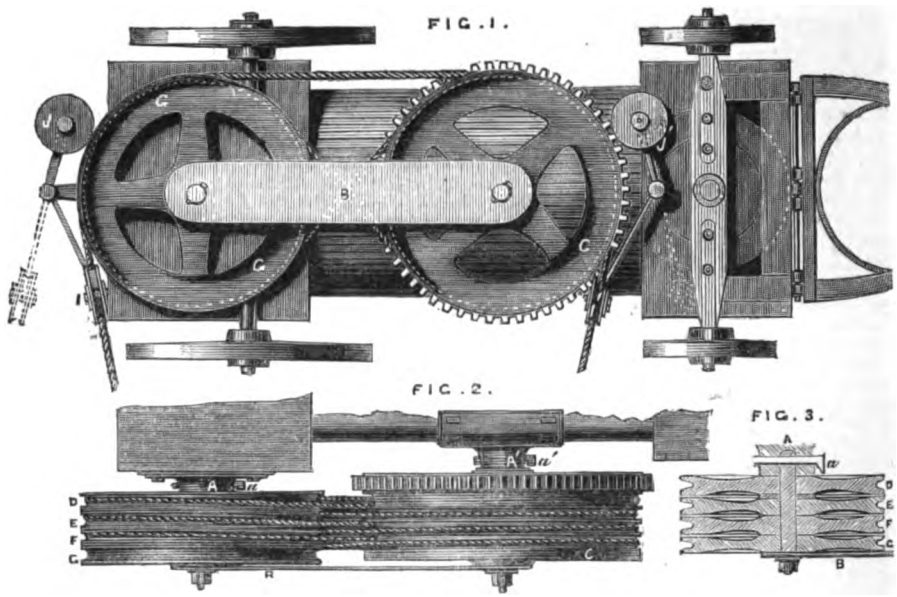
By giving n different values, tracing out the forms of the several curves, and finding the approximate areas in the manner already pointed out, the student will be enabled, when finding any curvilinear area the law of the curve of which is unknown, to fix the position of the ordinates, so as to obtain the greatest accuracy with the smallest amount of labour.

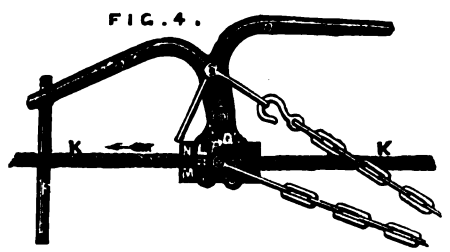
HALL'S PATENT AGRICULTURAL APPARATUS.

Mr. Collinson Hall, of Navestock, Essex, who is well known for his improvements in the application of steam power to agricultural operations, has introduced an invention which will greatly facilitate steam ploughing. Having had very ample experience of the difficulties which Mr. Hall's apparatus is designed to obviate, Mr. Fowler has taken steps to secure that apparatus, and has become the proprietor, we believe, of the patent granted for it to Mr. Hall. The invention is certainly a most valuable one, as it will obviate the principal defects of the existing steam-plough tackle. The following are the principal portions of Mr. Hall's specification of his patent:—

"Heretofore, in applying power to the cultivation of the soil by means of ropes, bands, or chains passing around drums or pulleys, the adhesion between the said ropes, bands, or chains and the drums or pulleys has, in the ordinary arrangements of apparatus, been found too small, and has in some cases been increased by additional contrivances. And my invention consists, first, of a new arrangement of drums or pulleys which obviates this objection. I employ a single drum or pulley upon one axle, and two or more drums or pulleys upon another. The rope, band, or chain is so passed round the drums or pulleys that one of the two, or more, which are upon the same axle turn in a direction opposite to that of the others, when the rope, band, or chain, is put in motion. The number of turns which the rope, band, or chain is made to take round the drums or pulleys will vary with the amount of power to be applied, the one increasing with the other. The arrangement described is that which I prefer; but I reserve to myself the employment of any and every equivalent arrangement whereby essentially the same action may be obtained. Secondly, in turning ploughs and other implements at the headlands, one wheel (usually the off-wheel) runs round and the near or opposite wheel remains at rest (in relation to its axis) or nearly so, and consequently obstructs the turning of the implement by encountering and displacing the soil. In order to remedy this evil, and thus facilitate the turning of the implement, I provide a small sole-piece or turntable, upon which the near wheel runs on reaching the headlands, and then is supported by it and turns upon it. Thirdly, in ploughing and otherwise cultivating by power it is, with ordinary apparatus, necessary for an attendant to signal to the engine driver (by means of flags or otherwise) when the implement reaches the headlands, that the engine may be stopped at a proper time. This signalling is often difficult and liable to failure, owing to certain states of weather, &c., and accidents to the apparatus sometimes result. To prevent this I connect with the implement a self-acting contrivance for loosening the rope from the implement at the required time. This contrivance may consist of an eccentric or a quick screw connected with a lever, and caused to join the rope ordinarily used and to be withdrawn from the rope by a fixed bar acting upon the lever; but any other equivalent contrivance may be employed for the purpose.

HALL'S PATENT AGRICULTURAL APPARATUS.

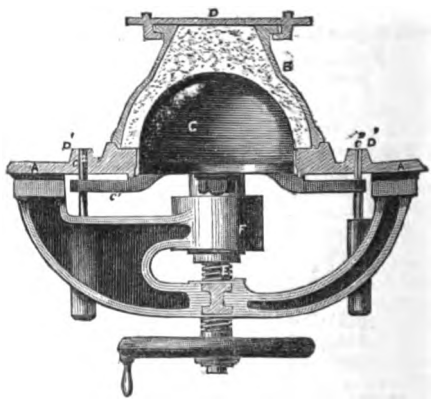




"In Fig. 1, 2, and 3 of the drawings hereunto annexed I have illustrated the manner in which I carry the first part of my invention into effect. Fig. 1 is a plan of the underside of a portable steam engine with my improved arrangement of drum and pulleys attached thereto. Fig. 2 is a side elevation of the said arrangement of drum and pulleys. Fig. 3 is a detached section of the set of separate pulleys on the same axle. The drum and sets of pulleys are suspended from the boiler by means of the cotters $a\,a'$, which are passed through the castings $A\,A'$ and the spindles of the drum and pulleys respectively. The castings A and A' are bolted permanently to the underside of the boiler, but the drum and pulleys may at any time be detached by removing the cotters $a\,a'$. The lower ends of the drum and pulley spindles are connected by a rigid bar of iron B, fixed by nuts screwed upon the threaded ends of the spindles. This bar gives perfect rigidity and all necessary support to the system of drum and pulleys without any other species of framework. C is the single drum upon the one axle, and D, E, F, G are the separate pulleys upon the other axle. The rope is wound about the drum and pulleys by preference after the fashion of a figure 8, as shown in Fig. 1, in order to get the best possible action. This arrangement renders it necessary that either the upper pulley D, or the lower pulley G, as the case may be, shall turn in a direction opposite to that of the remainder of the set. The whole system is driven by means of the cogged wheel H, into which gears a pinion driven by an upright shaft set in motion by gearing from the first driving shaft. $I\,I'$ are guide pulleys fitted in the simple manner shown for guiding the rope on to or off from the drum and pulleys, and J, J' are other guide pulleys carried by independent arms similarly fitted for keeping the rope in its proper grooves. The second part of my invention needs no illustrative drawings, inasmuch as any simple flat or concave sole piece, either working loosely within another so as to turn upon it, or simply remaining at rest itself and allowing the wheel to turn upon or within it, is sufficient for the purpose set forth. The manner in which I prefer to carry the third part of my invention into effect is illustrated in Fig. 4 of the drawings hereunto annexed. K is the ploughing rope which is supposed to be advancing in the direction of the arrow. L is a frame carrying a fixed block M, and a moveable block N, which is pressed upon by the toe."

JOBSON'S IMPROVED MOULDS FOR CASTING.

Mr. Robert Jobson, of Wordsley, Stafford, has introduced and patented an invention which has for its object improvements in apparatus used when making moulds for casting shells and other articles. For these purposes the pattern is made with arms carrying pins or projections, which enter sockets or receivers in the table or plate on



which the box is placed, and when in the first instance the pattern has been correctly adjusted on the table on which the flask or box is placed to have the sand rammed, the pins and the ends of the sockets (which receive them) are filed off, so as to make the ends of the pins and of the sockets coincide. By these means should any sand or material get in between the table and the pattern, the least incorrectness in the placing of the pattern will at once be detected by the workman when he

Digitized by Google

passes his fingers over the pins and the sockets. In some cases like means are resorted to in placing cores into moulds.

In order to dispense as much as possible with hand labour, in order to remove the sand after it has been used, and to damp it and to bring it into position to be again used by the moulders, apparatus is arranged whereby the sand is shovelled on to sieves, which are worked mechanically; the sand is damped, and the sifted sand is carried by a screw in a suitable trough or tube to the mixer, where fresh sand and other matters are added, and whence the sand is conveyed through another trough or tube by a screw into a position to be used by the moulder.

Again, in order, where heavy boxes or flasks are used, to reduce manual labour, a peculiar form of crane or apparatus is used, which consists of a quadrant, over which a chain or band passes; this quadrant receives motion by the moulder turning or giving motion to a fly-wheel, on the axis of which is a pinion which takes into and drives a cog-wheel, and on the axis of this is a pinion which takes into a curved rack fixed to the quadrant, which is counterbalanced when necessary, and which, in addition to turning on a horizontal axis, also turns to the right and left of the post or upright which carries it.

Fig. 1 shows a vertical section of so much of a table and apparatus used for forming sand moulds as will enable us to describe the peculiar character of Mr. Jobson's improvements. *A* is the table on which the flask or box *B* and the pattern *C* are placed when forming a sand mould in the box or flask *B*. The table *A* may be stationary on a suitable stand or frame, or it may be arranged in a suitable frame in such manner as to move on axes, necks, or gudgeons, and to turn thereon or therewith, so as for a time to bring its under surface uppermost, and its upper surface with the flask or box thereon undermost; the latter arrangement is preferred. When the table *A* is fixed, the box or flask *B* and the mould therein will have to be lifted and turned over in the ordinary manner; but when the table or surface *A* is made to move on or with axes, necks, or gudgeons, the table or surface *A* with the box or flask *B* and pattern *C* may be turned over by moving the table or surface *A* on or with its axes, after having first placed the cover *D* on the mould box or flask, in which case the flask or box will be temporarily fixed to the table or surface *A*, and when brought below there must, as heretofore, be provision for detaching and lowering the flask or box and the mould therein. The pattern *C* shown in the engraving is a half sphere, but any suitable pattern may be used in the place thereof, according to the article desired to be cast in the mould. The pattern *C* is formed with four arms *C'*, *C'*, with pins C^2, C^2, which enter sockets *D'*, *D'*, formed on the table or surface *A* as is shown, or in any other convenient manner. The pattern *C* is moved and partly withdrawn from the mould by means of a screw *E*, which passes through the fixed screw nut *F*. In constructing and adjusting the pattern and parts connected therewith in the first instance, in order to insure great exactness of castings made in a succession of moulds produced on the same patterns, the pins or projections C^2, C^2, are allowed to project through and beyond the sockets, and when the pattern *C* has been accurately adjusted in respect to the upper surface of the table *A*, the ends of the pins or projections C^2 are to be accurately filed off or removed, so that they may be smooth and flush with the ends of the sockets, by which means the workman, when he is about to make a mould in a box or flask placed on the table, will by simply passing a finger against the ends of the pins or projections C^2 and their sockets, immediately ascertain whether the pattern is correctly in position, and if not, he may readily adjust it correctly by moving the pattern upwards or downwards till the ends of the pins C^2 are exactly flush with the ends of their sockets. The arrangement and form of the pins or projections and their sockets may be varied, and such is the case in respect to the apparatus for moving the pattern. In like manner may cores be made with projections and moulds with sockets or receivers, so as to enable the workman readily to judge when a core is properly placed within a mould.

The European and American Steam Shipping Company is to be dissolved. A proposal made by Mr. J. L. O'Beenie to charter, on the part of a number of gentlemen, the eight ships of the company for three years was not accepted.

IMPROVED WATER-PRESSURE MACHINERY.

By Sir W. G. ARMSTRONG, C.E., F.R.S., Engineer to the War Department for Rifled Ordnance.

[Before his great gun gave Sir William Armstrong his novel pre-eminence, he was well known among engineers as the most successful improver of water-pressure machinery, and in the last volume of the Mechanics' Magazine we reported an elaborate lecture of Sir William's upon the subject. The official report of the proceedings of the August meeting of the Institution of Mechanical Engineers having now come to hand, we are enabled to lay before our readers illustrations of the improved machinery, with Sir William's own description of the same. We cannot do this without repeating a few sentences which appeared in our last volume; but we prefer to do this rather than render the paper incomplete. Although written in the third person, the paper which follows is by Sir William himself.]

The subject of water-pressure machinery first attracted the writer's attention about twenty-three years ago, on occasion of his noticing a small stream of water which flowed from a great elevation down a steep declivity and turned a single overshot wheel near the end of its course. Observing that the portion of the fall which was thus utilised by the wheel was not more than a twentieth part of the whole descent, he was forcibly struck with the inadequacy of the wheel as a means of realising the power of such a fall; and conceiving it practicable to render the entire head available by bringing down the water in a pipe, and causing it to act by pressure upon a suitable machine at the bottom, he applied himself to devising an engine to be worked by such a pressure. Other inventors, guided by the same idea, had been previously led to apply water-pressure in various ways to driving machinery, although the employment of that power had never been extensively adopted; but with these applications the writer was at the time wholly unacquainted.

After meeting with many difficulties and discouragements, the machine was produced, which after many years of seclusion in a lumber-room has now been brought out for inspection upon this occasion. It is, as will be perceived, a species of rotary engine, admitting of a continuous and uniform flow of water through it, and exempt from all contracted passages. This machine was tried first in Newcastle, with the pressure from the street pipes equivalent to a column of about 200 feet; then in Gateshead, with a still greater pressure; and in both cases it yielded a very high effect in relation to the theoretical power of the moving column.

Up to this time the writer's object had been merely to provide a machine for turning to profitable account the power which great altitude gives to mountain streams; believing then, as now, that when roads and railways have rendered accessible the valleys where such streams abound, the water which descends from the heights will ultimately prove an efficient source of motive power. But having then had practical experience of the power residing in street water-pipes, he conceived the idea of applying such power to the cranes at that time so slowly and expensively worked by hand upon the quay of this town. Accordingly after duly considering the means of effecting this purpose, a working model of a hydraulic crane was constructed, and exhibited at a meeting of the Literary and Philosophical Society of Newcastle, where it was connected with the town water-pipes, and went through the several operations of lifting, lowering, and slewing in a very satisfactory manner. The next step was to carry this scheme into actual practice; and in the year 1846 the first hydraulic crane was erected at the upper end of the Newcastle Quay, where it has ever since continued to do good service in discharging ships. The crane model exhibited to the present meeting is nearly identical with the original model, and does not differ materially from the first actual crane erected in this town.

The writer was soon enabled to introduce the hydraulic crane at Liverpool, and shortly afterwards at the New Dock at Grimsby, where, at the instance of his friend, the late Mr. Rendel, the engineer who constructed that dock, he also applied the same kind of machinery for opening and closing the lock gates and sluices. An extensive system of water-pressure machinery was accordingly carried out at that dock; and the result afforded the first practical demonstration that the pressure of a column of water could be advantageously applied as a substitute for manual labour, not merely for the cranage of goods, but also for various mechanical operations in connection with the entrances to docks. At all these places the effective column of water was about 200 feet head. At Newcastle and Liverpool the supply was derived from the pipes communicating with the town reservoirs; but at Grimsby a tower was built for supporting a tank, into which water was pumped by a steam-engine. In the former cases the irregularity of pressure, consequent upon the variable draught from the pipes for the ordinary purposes of consumption, proved a serious disadvantage; but this objection was not experienced at Grimsby, where the tank upon the tower furnished a separate source of power, undisturbed by any interferences. But the erection of a tower was a formidable undertaking, and so long as it remained a necessity, a great extension of the principle could not be anticipated. The writer therefore resorted to another form of artificial head, which possessed the advantage of being applicable, at a moderate cost, in all situations, and of lessening the size of the pipes and cylinders by affording a pressure of greatly increased intensity. The apparatus by which this is effected is named the "accumulator," from the circumstance of its accumulating the power exerted by the engine in charging it. The accumulator is in fact a reservoir giving pressure by load instead of by elevation; and its use, like that of every provision of this kind, is to equalise the duty of the engine in cases where the quantity of power to be supplied is subject to great and sudden fluctuations.

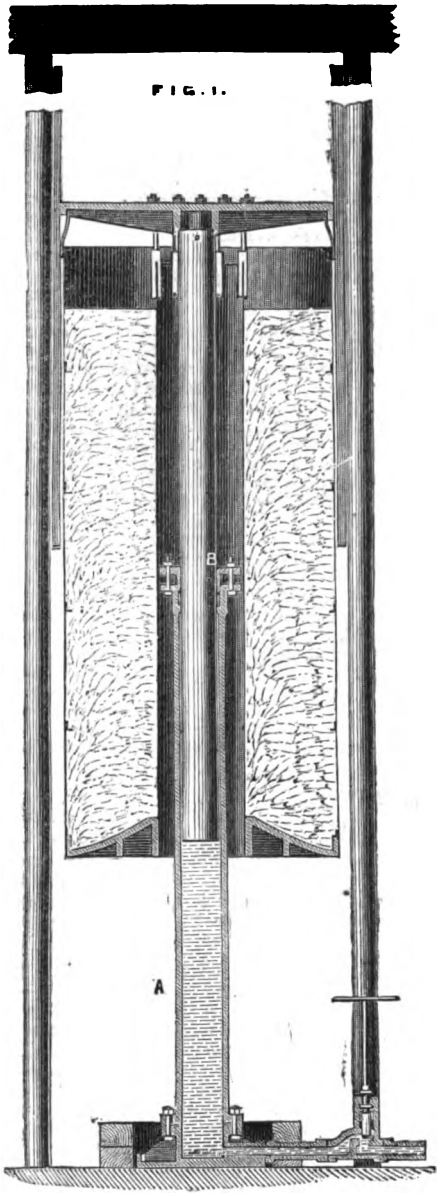
The construction of the accumulator is shown in the vertical section, Fig. 1. It consists of a large cast-iron cylinder *A* fitted with a plunger *B*, from which a loaded weight case *C* is suspended, to give pressure to the water injected by the engine. The load upon the plunger *B* is usually such as to produce a pressure in the cylinder equal to a column of 1,500 feet head; and the cylinder is made sufficiently capacious to contain the largest quantity of water which can be drawn from it at once by the simultaneous action of all the hydraulic machines connected with it. Whenever the engine pumps more water into the accumulator than passes to the hydraulic machines, the plunger rises and makes room in the cylinder for the surplus; but when, on the other hand, the supply from the engine is less for the moment than the quantity used, the plunger with its load descends and makes up the deficiency out of store. The accumulator serves also as a regulator to the engine; for when the plunger rises to a certain height, it begins to close the throttle valve in the steam-pipe so as gradually to reduce the speed of the engine, until the descent of the plunger again calls for an increased production of power.

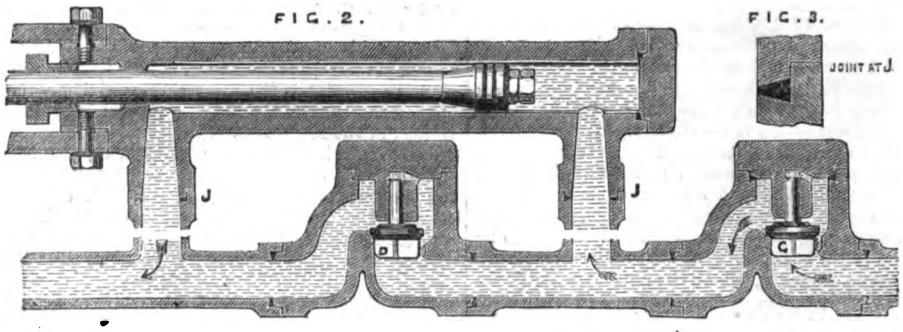
With regard to the pumping-engine used for charging the accumulator, the most approved form is that of two high pressure cylinders fixed horizontally, with double-acting pumps directly connected with the piston rods. At first a simple plunger pump at each end of the cylinder was used; then, with a view to greater compactness, the pump behind the cylinder was discontinued, and the other made a double-acting one upon the combined bucket-and-plunger system. Finally, a modification of this form of pump was adopted, by dispensing with the slack in the bucket and substituting an external delivery valve *D*, as shown in Fig. 2. In this arrangement the out-stroke of the pump causes the water contained in the annular space surrounding the plunger *E*, to be forced into the accumulator, while a further supply of water enters behind the piston *F* through the suction valve *G*; in the in-stroke the water behind the piston is discharged through the delivery valve *D*, and half of it passes round into the annular space on the other side of the piston, while the remaining half is forced into the accumulator, the area of the plunger *E* being exactly half that of the piston *F*. Each stroke of the pump thus delivers the same quantity of water into the accumulator. This neat modification of the bucket-and-plunger principle, by which equally easy access is given both to the suction and the delivery valves, was the suggestion of Mr. Henry Thompson, the writer's late intelligent foreman.

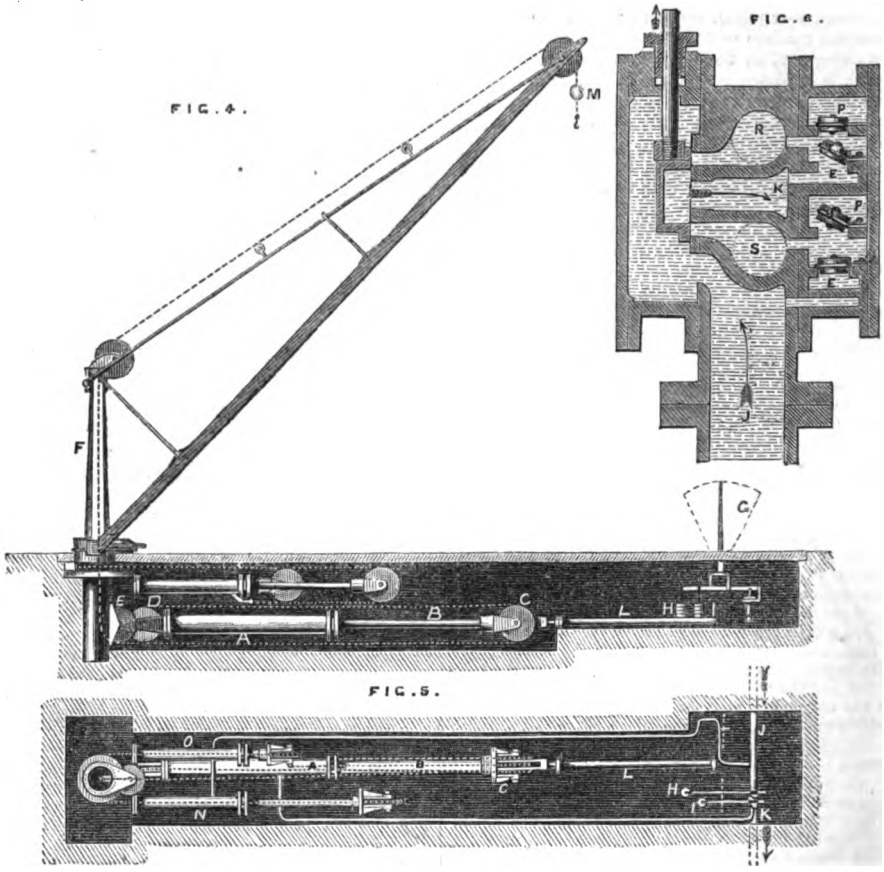
The introduction of the accumulator in the year 1851 removed all obstacles to the extension of water pressure machinery, which has since been applied in nearly all the principal docks, and in many of the Government establishments in this country. Nearly 1,200 hydraulic cranes, hoists, and other machines of that description have been applied; and 125 steam engines, collectively of more than 3,000 horse power, are now daily at work to supply the pressure for working them. The system has also been adopted in many of the principal railway stations, not only for cranage, but also for working turntables, traversing machines, waggon lifts, hauling machines, &c. It is also extensively used for raising and tipping waggons in the shipment of coal, for opening and closing swing bridges, and for many other purposes. New forms of application are continually being developed, and no

Digitized by Google

SIR WILLIAM ARMSTRONG'S IMPROVED WATER-PRESSURE MACHINERY.







doubt can be entertained of its capability of further extension.

The form of mechanism which prevails to the greatest extent in these various applications of water pressure consists of a hydraulic press with a set of sheaves used in the inverted order of blocks and pulleys, the object being to obtain an extended motion in the chain from a comparatively short stroke of piston. The general arrangement of the machinery for working a hydraulic crane is shown in Figs. 4 and 5; Fig. 4 being an elevation and Fig. 5 a plan. The pressure cylinder *A* for lifting the load is fixed horizontally below the surface of the ground in a chamber at the foot of the crane, and is fitted with the ram *B* carrying the pulleys *C* at its outer extremity. The lifting chain is made fast at one end to the cylinder *A*, and passes alternately round the moveable pulleys *C* and the fixed pulleys *D*, at the inner end of the cylinder *A*; and is then led round the guide pulley *E*, up the crane post *F*, and along the jib to the load. The motion of the lifting chain is controlled by means of the handle *G*, acting upon the inlet and outlet valves, which are kept closed by the weights *H* and *I*; by opening the inlet valve *H* the water is let into the cylinder *A*, from the pressure pipe *J*, and raises the load; and by opening the outlet valve *I* the water escapes from the cylinder into the exhaust pipe *K*, allowing the load to descend. The travel of the ram *B* in the outward stroke is prevented from exceeding the proper limit by the pulley block *C* coming in contact with a stop connected with the handle *G*, which closes the inlet valve *H*, and prevents the load from being raised too high. The return stroke of the ram is effected by the load suspended from the chain; and in the absence of any load a small supplementary ram *L* is employed to force the main ram *B* back, the slack chain being made to run out by the weight *M*.

(To be continued.)

ON MILITARY AND OTHER TENTS.

BY MAJOR GODFREY RHODES.

(Concluded from page 202.)

THE FIELD-OFFICER'S MARQUEE.

This tent is in shape and arrangement of its details, only a hospital marquee on a reduced scale. When pitched, it occupies about 126 square yards of ground, or 9 paces by 14; its weight when dry is about 173 pounds, and when wet 244 pounds, being an increase of 71 pounds. (See table of tents in the "Aide Mémoire to the Military Sciences," 1855-6.)*

THE CIRCULAR SINGLE-POLED CAMP TENT.

This tent, with some slight modifications, has been in general use in the British army for about 60 years (if not rather longer). Formerly, this tent consisted of one centre pole, without the short vertical wall with which the present conical tents are supplied; its height was 9 feet, its width about 12 feet, and it was capable of holding 12 men. A complete tent so constructed only weighed 43 pounds.

The following are the dimensions, &c., of the "circular conical single-poled tent" at present in use. I may premise by stating, that the British army tents vary both in size and weight. The diameter of this tent is 12 feet and 6 inches; height, or length of pole, 10 feet and 4 inches; accommodation for 12 to 14 men; weight of the linen tent (complete) when dry, is from 68 to 75 pounds, and when wet about 104 pounds. The height of the vertical circular wall is 12 inches, and its object is to give increased head-room to the soldiers when lying down. The number of pins required for this tent is 43; viz., 40 for the tension ropes and loops, and 3 for the long storm ropes. This tent is provided with one triangular entrance, and is deficient of a proper means of ventilation. The above sized tent contains about 512 cubic feet of capacity, allowing to each soldier about 64 cubic feet, 8 men per tent; about 51 cubic feet, 10 men per tent; about 42 cubic feet, 12 men per tent; and about 34 cubic feet, 15 men per tent.

GENERAL DEFECTS OF THE BRITISH ARMY TENTS.

Their general defects consist—1st., the canvas of which they are made is not always of the best

* This Marquee is not much used.

DETAILS.—1, *Ventilating cap with cover removed;* 2, *the same with cover on;* 3, *enlarged section of same with opening* A; 4, *external view of* 3, C *being cover, and* L L *lugs to receive ribs;* 5, *part of ground-rope and peg;* 6, *lower end of pole* H *with metal plate* E *and stop* G.

material. 2nd., the canvas and tent-ropes are not waterproofed; and, owing to their absorption of moisture, the weight of the tent is increased nearly-one third, and by their combined contraction, when wet, materially assist in pulling the wooden pegs out of the ground, thereby rendering the tent less secure during stormy weather. The alternate saturation and drying of the canvas and ropes must materially tend to rot them. 3rd., want of an improved method in the construction of the present army tents, from the apparent inability of applying to them, an efficacious and simple plan of thorough ventilation, &c., which, from the latter being very defective, together with over-crowding men into a confined space, is but too often the chief cause of those zymotic diseases—viz., "fevers," "diarrhœa," "dysentery," and "cholera," which latter are the greatest enemies to troops employed in active warfare. Young lads of 18 to 20 years of age are much more liable to contract zymotic diseases than men of 22 years and upwards; the former are generally deficient in physical strength, whereas the stamina of the latter being more fully developed, their constitutions are better able to bear the harassing fatigues incidental to armies in the field. To illustrate the point in question, I may perhaps be permitted to briefly mention "that during the campaign of 1809, some troops which were cantoned in the north of Germany, marched to Vienna, and, although the distance was only short, all the hospitals on the line of march were filled with sick: more than one-half of these men were under 20 years of age." Again, "during the year 1805, a French army, which was cantoned in the neighbourhood of Boulogne, marched about 400 leagues to join the grand army in Moravia, prior to the battle of Austerlitz, (fought 2nd December) but owing to the more matured physicalstrength of these men, (all above 22 years of age and 2 years' service) this long march was accomplished without leaving almost any sick in the hospitals on the line of route." With respect to No. 1 defect, I find that the two Commissioners (Sir John McNeill and Colonel Tulloch) reported in 1855-56, that some of the tents were of an inferior quality, and that in many instances the army was obliged to use the bell tent for hospitals, instead of the marquee, although the latter was far more appropriate for such a purpose. No. 2 defect: I have already called your attention to the increased weight of the army tents when wet; and, with respect to their general deficient waterproof qualities, I can state, from personal experience, that in the autumn of 1848, I was encamped for about two months with a detachment of my regiment

Digitized by Google

(then 2nd battalion 60th Rifles), at Kilkenny; and although the weather was not unusually wet for Ireland, still a misty dew penetrated the canvas, and rendered everything within the tent uncomfortably damp. During the winter of 1854, when I was in the Crimea, the general complaint of the British army tents was, that they were neither waterproof nor ventilated, and I can well remember the wet and puddled state of the windward half-ground portion of the interior of many of the tents, caused from the incessant beating of the rain and wind against the canvas, which latter was so ill adapted to resist the combined action of the rain and wind, for a continuous period of sometimes 10 days. On the contrary, the "Turkish circular conical tent" was dry, warm, and waterproof, owing to its covering being of double cotton canvas; besides, from its great width and comparative lowness, it withstood the fearful hurricane of the 14th of November, when nearly all the British and French tents were blown down. With reference to the deterioration of the tents from the effects of the variation in the weather, I find, on reference to page 123 of the printed "Report of the Sanitary Commission," which was despatched to the seat of war in the East in 1855-56, that in the month of May, 1855, the Commissioners recommended the striking and removal of some tents to a fresh surface, owing to the damp state of the ground inside the tents. The commissioners were informed that "the supply of tents was deficient, and that it was impossible to strike the tents pointed out, as they were too much decayed to admit of removal." No. 3. Defect: With respect to the very important subject of defective ventilation, &c., of the present army tents, I beg to bring to your notice the recorded opinions of several professional men. The late Dr. Robert Jackson, "Inspector-General of Army Hospitals," states, that "There is great room for improvement, in the manner ordinarily employed for covering troops from the inclemency of the weather, during a campaign." He recommends the use of a carpet of painted canvas to be laid on the ground, inside the tent; and by preventing the ascent of moisture, generated by the raised temperature within the tent, from its occupation (more particularly by the immediate, or near contact of the heated bodies of the men with the surface of the earth), would greatly tend to lessen those evils (arising from the contaminations of the air) to which soldiers are subject, when crowded together in close or unventilated tents. The Doctor recommends "a tent with a light roof," but acknowledges "that the application of it is connected with trouble." He further states, that "a roof, similar to that of a marquee, is liable to be overturned by strong winds, and a tent with close walls is liable to be contaminated." I must again refer to that valuable "Report of the Sanitary Commission" in respect to the general want of ventilation of our army tents. They state "That the most obvious sanitary defect in the tents was their want of ventilation."—"It is usual on a march for 12 to 15 men to sleep under a bell tent.—The cubic space for each soldier is 51 to 64 cubic feet, but the consequent evils from overcrowding tents would be greatly mitigated by ventilation. The indispensable necessity of renewing the interior atmosphere of the tent is indeed fully recognised, for there are a few small openings for this purpose near the apex of the tent, but they are of two small a size to be of use." Again, "We had occasion to examine the ventilation during the outbreak of cholera in May, 1855, and were struck on entering the tents by the foulness of the atmosphere. This led to inquiry, and we found the men were perfectly aware of this defect, and complained of it themselves, especially in the mornings." "At the same date we found instances of sick being treated under bell tents, and in going into one of these, we saw pans of peat charcoal on the floor, and were told by the surgeon that, were it not for the use of charcoal for absorbing the emanations from the sick, the air of the tent would have been unbearable—a very sufficient proof of the great necessity for a better ventilation." The Commissioners again state, "that to remove as far as practicable the evils of overcrowding tents, it appears indispensably necessary to improve their ventilation." With respect to the sanitary condition of the "Hospital Marquees," the Commissioners state that "the usual method of ventilation in 'marquees,' is by opening or raising the side walls; but this method can hardly be said to be sufficient, even in favourable weather, and still less is it when, from rain or high wind, the sides cannot be opened. Even in the fine weather, it was remarked that the air under the roof of the marquee was hot and stagnant (although the sides were open), because there was no provision for its escape above." The Commissioners state that "the whole question of ventilation, as regards field hospitals, is one of very great importance;" and with respect to the rapid recovery of the sick and wounded, they state that "well-ventilated field hospitals answer much better, than would be fulfilled by a much larger amount of ill-ventilated cubic space." Consequently, "to well ventilate a field hospital is, in other words, to save transport." They pointedly remark, that "a permanent and independent means of ventilation is particularly required at night, when the doors and side hangings are closed." In their concluding remarks, they state "that the atmospheric impurities arising from overcrowding and defective ventilation of tents and huts, were a frequent predisposing cause of zymotic disease." And that "as the neglect of the sanitary condition of camps, tents, barracks, and hospitals has hitherto, in all countries, climates, and seasons, been the cause of the largest amount of loss in armies, the whole subject (closely connected as it is with the physical efficiency of Her Majesty's forces) demands in future a practical development, commensurate with its importance to the public service." During the last three years and five months of the Peninsular war, at the period when the greatest activity prevailed, the mean strength of the British army amounted to 61,511 men, and the sick to 13,815, being 22¼ per cent. The mean ratio of inefficiency from wounds did not exceed 1¼ per cent. The average strength of the British army in the Crimea, during the ten weeks intervening between the 5th May and the 14th July, 1855, was 38,507 men. The total admissions into hospital were 22,541, or 58 per cent. of the force; the per-centage of deaths from wounds (exclusive of deaths in the field) was 20 per cent.; whereas 74½ per cent. admitted into hospital, and 96 per cent. of the total mortality from disease, originated from zymotic cases, such as fevers, &c.

MAJOR RHODES' TENTS.

With the view of supplying a remedy for the several defects of the present army tents, I will now briefly describe some tents of my own invention, not that they, being my own, merit a greater attention, but that I believe the proposed improvements will materially add both to the health and comfort, in all countries and seasons, of dwellers in tents, and I further hope may render "Tents and Tent Life" more acceptable. From the exposed diagrams, you will perceive that I have applied my system to three forms of tents, in all of which the same principle of construction is embodied. No. 1 represents the skeletons or uncovered frames of my field and hospital tents, from which you may easily comprehend the simplicity and strength of their construction. The frames are composed of stout ribs of ash, bamboo, or any other flexible material. When required to pitch the tent, the prepared double-twisted ground rope or band is hooked together, and laid to the full extent of its own circle on the ground; the butt-ends of the flexible ribs are then inserted within the loops or openings already made in the circular rope, and when the latter has been stretched out to the form required, the butt-end of each rib is forced into the ground; and to facilitate this operation, the extremity of the rib is provided with a metal shoe in the shape of a wedge. The butt is also provided with stops, so that the twisted rope or band, now circulating round the butt, cannot slip up the rib, nor can the butt be forced into the ground beyond those stops. To render the ground-rope more secure, a peg is driven over it at the centre between each rib. The top ends of the ribs (if detached from the butts) are placed into sockets, which latter are secured to the top ends of the butts; the ribs are now gradually bent inwards, and then inserted into the socket-holes of a head prepared for them. The latter has a large hole through its centre, for providing top ventilation to the tent. The canvas covering of the tent is then drawn over the frame, and when the outer ventilating head-piece covers the inner one, the bottom part of the tent-covering is strapped to the ground-band, by the means of straps fixed to the inside canvas of the tent, near its base. The tent is thus complete; but to add increased stability, eight short outside storm-ropes, previously attached to the canvas, are stretched out and pegged to the ground. To further add to the firmness of the structure, the outside valise or canvas bag, in which the whole tent was rolled up, is divided into two parts, and then buttoned to the inside of the lower part of the canvas of the tent, on buttons prepared for that purpose. On that part of the canvas which lies on the ground, are placed the butt ends of the arms, the knapsacks, and other articles usually required by a soldier in the field; by this extra weight being laid on the canvas ground curtain, at the sides of the tent, all round its base, not only greater stability is given to the tent, but, what materially benefits the men in a sanitary point of view is, that the usual ground currents of air which enter at the bottom of the tent, do not by the above means blow direct on the bodies of the men, thereby obviating the necessity of providing straw to place round the bottom of the tent, which at present is absolutely necessary to prevent the men from getting stiff necks: by this simple arrangement, the purchase of straw usually supplied for tents is obviated; and what must be clearly perceived is, that fewer men are liable to catch cold, consequently the hospitals would be much less encumbered, and the army rendered much more efficient. It is the prevention and not the cure of such trivial complaints that should be most attended to. When it is necessary to light a small fire within the tent, the exterior ventilating head can be uncovered, so that an easy and free egress of the smoke, is obtained. With respect to the saving of space, when ground is an object, I can pitch five of my hospital-tents on the same number of square yards of ground as is required to pitch (including room for the tent-ropes) one Government hospital-marquee—thus, one of the latter requires about 340 square yards of ground (or 20 paces by 19), whilst five of the former only require about 215 square yards of ground. The space necessary for one of my hospital-tents is about 63 square yards, or about 7 paces by 9. This, is a decided advantage, when but a small space can be procured for the encampment of troops. My field-tents can, if required, be pitched within a few inches of each other, thereby also occupying much less space than the circular conical government tents. The cube quantity of air contained in my tents is as follows:—"*Hospital-tent*," 30 feet long, 15 feet wide, and 10 feet high, is equal to 2,383½ cube feet; or about 119 cubic feet for each soldier, having 20 men in the tent; or for 30 men, about 79½ cubic feet each. "*Field-tent*," 13 feet diameter and 8 feet high, is equal to 531 cubic feet; or, for 8 men in a tent, about 66½ cubic feet each: and for 12 men, about 44¼ cubic feet each. "*Guard-tent*," 9 feet diameter, and 5 feet in height, contains about 159 cubic feet. An ordinary "single-poled circular conical tent," without any side walls, but occupying the same space of ground, and of the same height and width as my field tent, contains about 354 cubic feet of air, thus allowing about 44¼ cubic feet for each man, 8 men in the tent; and about 29½ cubic feet for each man, 12 men in the tent. I beg to state that all my tents are perfectly ventilated, and that the government tents are deficient in that most important particular. The number of cubic feet of air allowed to each soldier in many of the

Digitized by Google

barracks in England is only 3 feet, whereas for prisons, the rule is 1000 cubic feet per individual. You will perceive that the colour of the canvas of my tents is grey, and that of the Government tents is generally white, or of a very light colour. The glare from white canvas is not only very objectionable for the eyes, but is also easily seen from a great distance, thereby often disclosing to the enemy, those strategical movements, which, if the colour of our tents were of a dark-grey, he would be ignorant of. In conclusion, I beg to read a few extracts from an official report on the "Suitability, &c., of my Tents," as applicable for military purposes, based on reports of their actual occupation by troops in the field, which his Majesty the King of Hanover has been pleased to grant me.* With respect to the adoption of my tents for military purposes, I beg to state, that having submitted, last year, plans and small models to several Governments, I have been honoured with orders, and have supplied three full-sized trial tents to the following States, viz., England, France, Austria, Prussia, Russia, Sweden, Belgium, and Hanover; but owing to the lateness of the season, and the fact of the troops having taken up winter quarters, my tents have not yet been practically tried, except by the Hanoverian Government. I may state, that although the "Special Military Committee," composed of several general and other superior officers commanding regiments, which were assembled in Dublin on the 3rd of July last (at my request, and by order of His Royal Highness the General Commanding-in-Chief), so strongly recommended that tents of my construction should be immediately sent to the camps of Aldershot and the Curragh, for the purpose of undergoing practical trials by the troops then under canvas; I regret to say that only one set has been ordered, and that, owing to its very late arrival last year at Aldershot, my tents have not yet been practically tried by the troops, but have been partially tested.

* These extracts were highly favourable to the inventor of Major Rhodes.

NEW CHEMICAL BALANCE.

By Mr. J. B. COOKE, of Liverpool.

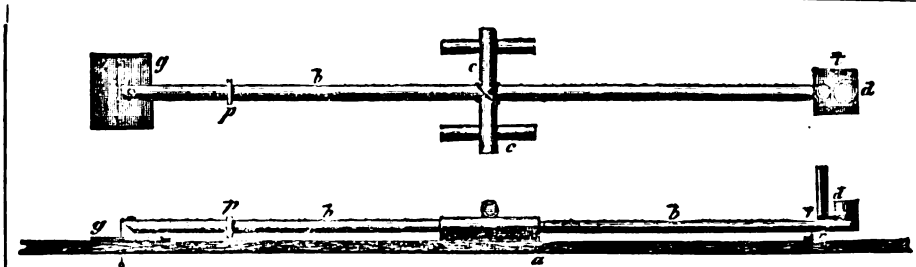
THE balance is an instrument of prime necessity to the exactitude of the results sought for in the operations of the chemist. But it is also a very expensive piece of apparatus, and its delicacy requires it to be guarded with the utmost care from the effects of damp, and the other vapours and fumes incidental to a laboratory. The following is the description of an instrument which has been in constant use for more than a year, and which is at once sensitive, effective, inexpensive, and not liable to injury. It weighs quantities amounting to 2.400 grains with an accuracy unmistakeably distinct to the $\frac{1}{100}$th of a grain.

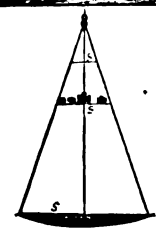
Though freely exposed to an atmosphere which in twelve hours covers a polished iron surface with rust, and which is often loaded with fumes of hydrosulphuric and other acids, it is now as sensitive as on the day of its construction.

The materials of which this balance is composed are to be found in every laboratory. Their first cost need not amount to 5s., and they can be put together by the chemist himself in the course of two or or three hours, so as to be in perfect working order.

To those operators whose object is the attainment of accuracy with the smallest expenditure of means, it is hoped that a desideratum is here supplied, although some of the points usually considered essential to a good balance appear to be disregarded.

The beam is formed of glass tube. A piece of barometer tubing of 12 or 18 inches in length, or even the full length of a barometer tube, if economy of space is not important, may be employed. Another glass tube of about three inches in length, and of diameter and thickness proportioned to the weight it is destined to bear, is attached to the beam tube at right angles, at about the middle point of each. Exactitude in any of these particulars is not essential. The





attachment may be made by any convenient means, say by fine iron wire, covered afterwards with sealing-wax melted on to it.

If a portable balance be desired, a suitable stand must, of course, be provided; but if the instrument be intended to occupy a permanent position, it may be made to work upon an open shelf, and the present description applies to the latter circumstances.

Two other glass tubes, of about two inches in length, are cemented longitudinally upon the surface of the shelf, parallel to and at a distance of $1\frac{1}{4}$ inches from each other.

They must be equal to each other in diameter, which must be greater than that of the beam tube, or they must be raised equally to some small distance above the surface of the shelf, so that, when the transverse tube attached to the beam is placed across and upon them, the beam itself, lying between and parallel to them shall be raised at its centre at least $\frac{1}{4}$-inch above the shelf. The three small tubes should be selected of good shape and polish.

By this arrangement the beam, when in equilibrium, is supported upon two points, which, owing to the roundness, smoothness, hardness, and chemical inertness of the material, approximate closely to mathematical points not liable to injury from oxidation or friction, Knife-edges working upon planes of whatever substance, are not theoretically so perfect in action as the above *points* of support, and it would be difficult with the finest art to make them practically more sensitive.

A piece of sheet-copper is fastened on to the shelf under the beam near each of its ends. An edge of each piece of copper running transversely to the shelf is turned up at right angles to serve as a support at such a height that when one end of the beam, loaded with its full weight, is resting upon one of them, the other end may be separated from its resting place by about $\frac{1}{10}$th of an inch. If the under-surface of the beam be blackened about these places of support, the separation shows very distinctly against a white surface placed behind.

The weights, and substance to be weighed, are both applied at the same end of the beam; the other end being compensated by a constant counterpoise; a peculiar form of scale pan is therefore required. It is convenient to have three tiers of pans hung in a pyramidal form at a suitable distance from each other by the same three silk strings. The largest and lowest is destined for the substance to be weighed. The middle one in size and position for the larger weights, and the smallest and uppermost pan contains the weights below 10 grs. This compound scale pan is suspended by a bent wire to a loop formed at one end of a short silk thread, which, passing vertically through a small hole in the shelf, and bisecting the end-section of the beam tube, is cemented with sealing wax on the upper surface of the tube. The thread should lie in a slight notch filed on the upper circumference of the end of the beam, and should hang freely from it, the lower circumference being ground away to prevent contact. The thread must also of course be carefully protected against contact with the sides of the opening in the shelf. The better way is to make an opening of about one inch square through the wood, and afterwards to cover over the greater portion by four slips of window-glass crossing each other, and leaving only a small hole in the centre for the thread. If this opening be large, the balance will be affected by currents of air which always occur upwards or downwards in such circumstances. The surface of the shelf between the centre of the beam and that end of it to which the pans are hung is divided into 10 equal parts by ink lines; and a platinum rider weighing $\frac{1}{10}$th grain is applied to this arm of the beam, and by traversing over each division marked on the shelf causes the variation of $\frac{1}{100}$th of a grain, and dispenses with the use of weights smaller than $\frac{1}{10}$th gr.

The sensitiveness of a balance is proportional to the approximation to each other of the centres of suspension and of gravity. In the present instance, the centre of suspension is the central point of the mid-section of the small tube attached to the beam, and since the weights of the beam itself and of the scale pans and their contents, are referred to a point much below this, some provision is required by which the centre of gravity of the whole mass may be considerably raised, and its position nicely regulated. The provision required is found in the mode by which the compensation is applied at the end of the beam destitute of scale pan.

On the upper side of the compensation-end of the beam is cemented horizontally with shellac, a table of window-glass of about 1 inch square surface. On this table again are cemented, by the same means, in vertical juxtaposition, two glass tubes; one about 3 inches high and $\frac{1}{4}$-inch in diameter, the other 1 inch high and $\frac{1}{4}$-inch in diameter. A quantity of dry pure mercury is then poured into the tall tube until the beam, whose scale-pan is loaded with about $\frac{2}{3}$rds the weight which it is destined to carry, is nearly in a state of equilibrium. If the tall tube be sufficiently high and narrow, it will then be found that the centre of gravity has risen above the centre of suspension, as will be evidenced by the setting of the beam at either end indifferently according as it is placed.

Mercury is now poured gradually into the shorter tube, and after each addition weights are added in the scale-pans to produce equilibrium. By every such addition the centre of gravity will be proportionally lowered, and may be brought with the utmost nicety within any assignable distance from the centre of suspension.

The adjustment will suffice for the purpose of the balance, when the transference of the rider over one division of the shelf towards the centre of the beam shall raise this end of the beam from its supports, and the replacing of the rider in its former position, shall restore the preponderance of the weights, and when on frequent trial this the invariable result.

The balance is thus left with an extremely small amount of overpoise. The substance to be weighed is placed in the lowest pan. Weights are removed from the upper pans, and ultimately the rider is moved over the arm towards the centre, to the point at which the beam is first caused permanently to resume its normal position. The sum of the weights removed, together with the number of degrees passed over by the rider reckoned as $\frac{1}{100}$ths of a grain, will be the weight required.

The advantages claimed for this balance are, easy construction, cheapness, non liability to injury from exposure or rough handling, the whole operation of weighing being confined to one end of the beam without loss of sensitiveness, and the separation of the large from the smaller weights.

The annexed engravings illustrate, in plan view and side elevation respectively, the new balance. *a* is the shelf; *b*, the beam; *c c c*, three small tubes; *d d*, tubes for mercury; *s s s*, three scale pans; *g*, glass plates to cover; *h*, hole in shelf; *p*, platinum rider; *t*, small table; and *r r*, copper rests.

he method of mounting is not inferior in sensitiveness to that of the best constructed instruments, and the limits of its sensitiveness are far from being reached in the specimen above described. As an illustration of this assertion, the following rough experiment is adduced. The writer constructed a balance, of which the beam was a tube of thick glass 22 inches long, and one inch in external diameter, and weighing alone $1\frac{3}{4}$ lb. The scale pan was loaded with a weight of 1 lb. The compensation was then readily effected with mercury to such accuracy that the translation of a platinum rider weighing $\frac{1}{10}$th gr. along the beam, over a space equal to $\frac{1}{15}$th of the length of the arm, sufficed to change the preponderance in favour of the one arm or the other, according to the direction of its transference. This roughly-formed balance therefore, which, exclusive of the scale pan, did not occupy two hours in construction and preparation for use, was sensitive to a weight of $\frac{1}{100}$th of a grain, or to $\frac{1}{700000}$th part of the weight to be estimated, and about $\frac{1}{3000000}$th part of the whole weight supported on the fulcrum.

NOTICES.

We are compelled to postpone until next week. Plato (On Iron Dwellings), S.B. (On the Atlantic Cable), Captain Norton (On Concussion Fuze), and articles on Fishing Tackle and Jobson's Apparatus for Crushing.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

The demand for Mr. E. J. Reed's paper—

On the Modifications which the Ships of the Royal Navy have Undergone during the Present Century, in respect of Dimensions, Form, Means of Propulsion, and Power of Attack and Defence,"

has been so great that the Journal of the Society of Arts, the Mechanics' Magazine, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

ELECTRO-MAGNETISM.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

Gentlemen,—In the Mechanics' Magazine of Friday last (No. 13), I have read with much interest the account of Mr. Haines' experiments with different cores, which seem to have been made with great accuracy; and I doubt not they will be equally interesting to not a few of your readers. With regard to the concluding part of his letter, my first impression was, that by a suitable extension of the core the power of the coil might be increased, but on further reflection, I am convinced that by any addition to the core at one end we only condense or concentrate the magnetic polarity at the other, and, therefore, do not gain any augmentation in the total amount of magneto-inductive force exerted upon the primary coil, but probably rather a diminution in consequence of the diffusion of part of the magnetism in that part of the elongated core which extends beyond the coil. If this be the case, the only advantage obtained is increased energy at one of the holes of a bar electro-magnet—an advantage which may evidently, in some circumstances, be turned to good account.

I observe a typographical error in Mr. Haines' letter, which it may be useful to point out, namely, the word *taking*, which ought to read *tripling*.

Glasgow, 28th March, 1859. Geo. Blair.

LIST OF NEW BOOKS.

Brown's Mercantile Navy List, 1859, 7s. 6d.

Simmons's (Capt. F. C.) Leading Principles of Gunnery, 8vo, [illegible], cl.

Our Weekly Gossip.

We learn that the secret system presses uneasily, as we anticipated, upon Sir William Armstrong, especially since the novelty of his invention has been called in question—openly by some, privately by many. This fact has, if we are rightly informed, induced Sir William to proceed with his application for a patent in the usual way. His name will accordingly be found on page 210 of our last Number in the list of those who have given notice of their intention to proceed with their applications for patents. It should be understood that any person may enter an opposition to the granting of Sir William's patent, on the ground of want of novelty, on or before the 11th of April. It is probable, however, that those who would be best able to prove it old, if it be old, will be least likely to trouble Sir William with opposition. The absence of opposition will by no means establish the novelty of his invention.

The number of the "Commissioners of Patents Journal" for Tuesday last, March 29, although purchasable for 2d, will be of very great value to patentees and others. It contains a complete list of the specifications of patents for inventions enrolled under the Old Law (prior to October, 1852), with the prices at which the printed specifications of the whole are published. The list also includes all those old law patents with which specifications were not enrolled, together with memoranda of all surrenders and disclaimers. The average price each of the printed specifications is a few pence, but some of them are so bulky as to cost several shillings; 10s. 4d. is the highest that strikes our eye on hastily glancing at the list, but we remember having before seen one or two, if we mistake not, as high as 15s. The whole number of these documents is 14,359.

Captain Blakeley, whose improvements in ordnance are well known to the scientific public, writes to us as follows:—"We have all heard of the great 13-inch wrought-iron cannon, the gift of the Mersey Steel Company to the nation, yet its merits have been little discussed in public, probably because it was a gift, and a most generous one. The impression, however, has become general that this gun is cracked in the inside in consequence of firing. I myself fell into this error, when I saw the fissure, and have since spoken and written of the gun as having shown a want of sufficient strength. This makes it my duty to do what I can to remove the erroneous impression which exists, and I shall, therefore, be grateful to you if you will allow me to make known through your columns that I have discovered that the small fissures in the inside of the barrel of this magnificent gun have not been either caused or sensibly increased by firing, but were found when it was bored, and were pointed out to the officer of artillery sent to receive it."

The extraordinary piece of ordnance mentioned in the preceding paragraph by Captain Blakeley, will in a few days be permanently placed in its position to form part of the sea-defences of Portsmouth. Midway between Southsea Castle and the western auxiliary battery a bed of concrete has been made in the shingle seven feet in depth, and on this the gun, with its carriage, platform, and loading crane, will be erected. The gun commands the entrance to the channel of Portsmouth harbour. The following are the dimensions of the gun, as given in the *Times*:—Length of gun—From breech loop to muzzle, 16ft. 6in.; from base ring to muzzle, 13ft. 8in. Base ring—Circumference, 11ft. 4in.; diameter, 3ft. $7\frac{1}{2}$in. Muzzle—Circumference, 7ft. $1\frac{1}{4}$in.; diameter, 2ft. $3\frac{1}{4}$in. Bore—diameter, 1ft. 1in.; length, 13ft. $3\frac{1}{4}$in. Thickness of metal at breech, 1ft. 10in., at vent, 1ft. 3in.; at muzzle, $7\frac{1}{4}$in. Trunnions—Circumference, 3ft. $1\frac{3}{4}$in.; diameter, 1ft.; length of shoulder, $11\frac{3}{4}$in. Distance from centre of trunnions to base ring, 5ft. $4\frac{1}{2}$in.; to muzzle, 8ft. $3\frac{1}{2}$in. Circumference of gun round the centre piece or band, 12ft. 9in.; weight of gun, 22 tons; weight of shot, 3 cwt.; service charge of powder, 78lb. The carriage and platform were manufactured at Woolwich of teak, and are bolted together in the strongest possible manner. The carriage weighs 3 tons 2 cwt.; the weight of the platform is 4 tons.

"Electrical Physiognomy" is the only title we can find on the instant for a curious subject introduced a few days since to the members of the Club of the Scientific Press of Paris, by Dr. Mallet. A medical man named Ducheune, of Boulogne, has given much attention to curative electricity, and has thus been led to make a series of curious and important experiments by means of electrical currents on the duty of the various muscles of the human face, from a physiognomical point of view, and has produced a kind of chart illustrative of those functions for the use of those who take any interest in the study of physiognomy. The muscles of the face are set in action by electrical excitation, and the various changes produced are recorded by photography; so that M. Ducheune's chart is, in fact, an album of physiognomical photographs. The experimenter has naturally attached a nomenclature to his album; he calls the great frontal muscle the *muscle of surprise*, and says that its elevation indicates astonishment, attention, and surprise, and his may be studied conveniently at a theatre, at the moment of the rising of the curtain. The contrary action, ex ressive of reflection, is said to be caused by the depression of the brow caused by the action of the orbicular muscles in the eyelids; for this reason, the name given to this latter muscle is the *muscle of reflection*. The little muscle which prickers up the brow in the centre is named the *muscle of pain*. The pyramidal muscle which strides the roof of the nose is considered to indicate ferocity, and is called in the new physiognomical list the *wicked muscle*. The two zygomatic muscles are called the *laughing and crying muscles*; and so on throughout. In order to ascertain the degree of influence exercised by the muscles on the countenance, each was put in action apparently when the face was in repose, and to render the experiment more decided, the subject acted upon in most cases was an old man with a blank face partly paralysed. The muscles were first made to contract one by one, and the results tabulated as expressive or inexpressive; they were then made to contract in twos and threes, and the effects of these contractions are called *concordant* or *discordant*, according as their simultaneous excitement produces the effect of a single well-defined passion, or a mere grimace. One thing seems to be proved by these experiments, namely, that several physiognomical changes which were supposed to be the result of the combined action of two or more different muscles, are in reality produced by the contraction of one single muscle or pair of muscles alone. The experiments were made on one side only of the face, so that each photograph has an excited and a non-excited side. These two might not very inappropriately be called physiognomical positives and negatives. This application of electricity and photography combined may be of great use to artists.

Aluminium could heretofore be cast, moulded, forged, and chased like other metals, but there was a difficulty, or, at any rate, great inconvenience, in soldering it. This has confined the application of the metal to such objects as could be produced in one single piece, and, as all practical men know, this class excluded a very large majority of articles not only of ornament, but also of utility. A silver coffee pot, for instance, often consists of from ten to twelve pieces; the spout is made in two pieces soldered together, and is then of course soldered on to the body; the cover mostly consists of at least four or five pieces. The shops of Paris are filled with small ornamental articles generally struck up in one piece; and plates of aluminium have been largely used in contrast with gold, and with ornamental and carved woods, in the fabrication of small coffers and boxes, and in the ornamentation of cabinet work. But the lightness of the metal makes it peculiarly applicable for many articles of utility, and therefore it has been an object of considerable interest to find an easy mode of uniting several pieces together. M. Mourey, of Paris, has given much attention to the subject, and, having succeeded in his object, he has thrown open his discovery to the world by describing and experimenting upon it before the members of the *Society for the Encouragement of National Industry*. This gentleman, having failed in all his attempts to solder aluminium as other metals are soldered by preparing the two edges and at once uniting them by means of a more fusible metal or alloy, was driven to various experiments, and the following is the plan he now recommends:—He prepares each piece separately by covering its edge with a preliminary solder, composed of aluminium and zinc, and he then unites the two edges by means of another solder containing a larger proportion of aluminium; and he thereby obtains a perfect joint. He prepares the edges with a mixture of turpentine, balsam of copaiva, and lemon juice; the pieces are placed over hot charcoal, and a jet of flame is blown along the part to be soldered; the joint is then covered with morsels of an alloy composed of six parts aluminium and ninety-four parts zinc; these being melted adhere to the surface and are pressed down by means of small tools made of aluminium. The difficulties of the operation are said to be not greater than in the case of hard soldering of copper. When the two parts to be united have been prepared as above described, they are held together in the usual manner, and soldered by means of an alloy consisting of eighty parts of zinc and twenty parts of aluminium. The joints thus made may be worked or touched up as though they consisted of the unalloyed aluminium.

Mr. J. Downie, of North Woodside Ironworks, has read a paper to the Glasgow Philosophical Society on a new design for river steamers for passenger traffic. Mr. Downie proposes a sort of compromise between Yankee and British vessels—a steamer with the main deck lowered four feet from its present level, the side plates partly removed and replaced with strong plate glass, the side plates to be used in stiffening the hull, and a roof run the whole length fore and aft over the maindeck. A vote of thanks was given to Mr. Downie for his paper, but opinions were expressed that such a vessel as was proposed would scarcely be safe with an upper deck of the nature described, as there would be danger of an upset if the passengers ran to one side of the ship. Mr. Neilson thought that the objection might be removed by narrowing the upper deck.

The new rifled Ordnance Department, in the course of organization in Woolwich Arsenal for manufacturing Sir W. Armstrong's guns, under the superintendence of Mr. J. Anderson, according to existing arrangements, will commence operations early in the month of May. Sir W. Armstrong, it is said, has expended upwards of 7,000*l.* on the initiatory experiments to test the efficiency of his invention.

Mr. F. A. Abel, the chemist to the War Department, has been making a series of experiments on the practising ground of the Royal Engineers at Brompton, Chatham, with an invention of his for firing charges of mines, blasts, &c, by magnetic agency, instead of by the old plan of fuses and slow matches. The experiments have been carried out in presence of a number of Royal Engineer officers of eminence now at head-quarters, all of whom have expressed themselves satisfied with the trials.

Dr. Lardner recommends a resort to destructive agents intended to operate not mechanically, like existing instruments of war, but chemically, for war purposes. Compounds are known, he says, in chemistry which, when exposed to the air, spontaneously ignite, diffusing through the surrounding atmosphere gases, or vapours, of odours so insufferable that men forced to respire them would be rendered utterly incapable of all effectual action. Shells charged with such compounds, exploding in the gunroom of a vessel, or anywhere between decks, would, without destroying life or limb, disable the enemy. There are others of a more formidable character. There are the "kakodyles," of which arsenic is one of the constituents, which on exploding not only diffuse exhalations which render the surrounding atmosphere so fetid as to be absolutely insufferable in respiration, but impart to it also qualities which are poisonous in the most deadly degree. These compounds being eminently volatile explode spontaneously when exposed to the air. In burning, the metallic arsenic, one of their constituents, combining with the oxygen of the air, forms fumes of white arsenic, which, being diffused through the surrounding air, kill all who breathe it. But the laboratory can furnish agents still more destructive. There are compounds into which the gas called cyanogen enters in combination with arsenic. A shell charged with such a compound upon exploding would produce terrific effects. By the explosion of such a shell the surrounding air would be instantly impregnated with the vapours of two of the most fearful poisons known in medicine. Before such agents, says the Doctor, gunpowder would "pale its ineffectual fires."

Messrs. Miller and Taplin have delivered an official report on the comparative merits of Newcastle and South Wales coals for steam purposes. They state the result of their experiments to be that the Welsh coal is 5·3 per cent. better than Newcastle in economy, but that the latter is 1·5 per cent. better than the former in regard to the rate of evaporation. On the whole, the advantages of the one description of coal over the other are scarcely appreciable, and the report recommends that another trial should be made in the Government Dockyards by Government officials without the presence of either interested party.

At the date of the last report of the chief inspector of the Manchester Association for the Prevention of Boiler Explosions, that society had 1,486 boilers under inspection. Of these 107 are found to be defective, from causes classified as follows:—Corrosion 20, of which 6 were dangerous; fractures, 3; safety valves over-weighted and otherwise out of order, 31; pressure gauges out of order, 20; water gauges out of order, 17; feed apparatus out of order, 5; blow-off cocks out of order, 9, 1 dangerous; and deficiency of water, 2. Ten boilers are reported as without glass gauges; 28 without blow-off cocks; 3 without pressure gauges; and 7 safety valves had the spindles passed through stuffing boxes.

A body of workmen, 300 to 600 strong, are about to be set to work on the Crinan canal, on which a serious accident recently took place.

The death is announced at Edinburgh of Mrs. Taylor, widow of the late Mr. James Taylor, whom Scottish writers contend was the first to apply steam to the propulsion of vessels, having launched a small steamboat on Dalswinton Loch in October, 1788.

One of Boydell's traction engines is now working between Manchester and Little Hulton. Another item of Manchester news is the appointment of Mr. Joseph Baxendale as "Corporation Astronomer," in the room of the Rev. H. H. Jones, deceased.

Mr. W. T. Ansell has undertaken the management of the Levant telegraphs.

The work of clearing the Nene of the dams placed in it by the Nene Valley Drainage Commissioners is being actively pushed on, but the complete removal of the piles of the Waldersea dam will not be effected for a week or two. The wings are cleared away, and an opening has been cut for the passage of the water, so that there is now no impediment to the drainage. The Wisbeach Corporation insist on the removal of every obstruction in the river up to Peterborough.

At a meeting held last week by the Hexham Farmers' Club, the cost of cutting an acre of an average crop of wheat (28 bushels) by the various methods of reaping was estimated as follows:—By sickle, 12s.; by scythe, 9s. 6d; by machine with side delivery in swathe, allowing the machine to cut 12 acres per day, 3s. 10d.; by machine with back delivery, allowing 9 acres per day, 3s. 9d. The decided comparative economy of reaping machines is too obvious to require comment. The Hexhamites expressed a preference for machines with back delivery.

From the progress made on the Salisbury and Yeovil and Yeovil and Exeter lines, it is expected that through narrow guage communication will be established between Exeter and London in the course of eighteen months.

A report of the Ordnance Survey and Topographical Depot to the end of the past year 1858, was published last week. It gives a detailed account of the progress of county, parish, and town plans and military surveys. The expense for the Ordnance surveys to be provided for in the current year's estimates is £90,000. The sale of ordnance maps last year realised the sum of £5,499, including those supplied to public-offices, &c.

In spite of the decision of the Committee of the Stock Exchange, the works on the Aidin-Smyrna Railway are continued with energy. The difficult cutting at the beginning of the line has been finished; and what remains now up to the tunnel is one uninterrupted plain, where scarcely any earthworks are required. At the tunnel itself the diagonal shaft on the Aidin side has been sunk to 50 fathoms, during the first 25 or 30 feet through solid limestone rock, after which a layer of clay was found, very easy to work, and yet of sufficient consistency not to require masonry. Thus, the most formidable part of the line promises to give far less trouble than was expected.

"An attempt is in progress on the part of the Great Western Railway Company which is likely," says the city article of the *Times*, "should it prove successful, to destroy the only protection enjoyed by the public against a constant increase of the evils of the monopoly conferred by Parliament on this and all similar undertakings. A private Bill has been introduced, in a covert form, to enable them at pleasure to raise their fares for passengers and goods to an extent ranging from 50 to 100 per cent., as well as to acquire other powers with the view, apparently, of screening their arrangements from observation. It is stated to have been merely by accident that the trading community discovered the project in time to take steps for its defeat. The Bill is entitled 'A Bill for authorizing the construction of a railway for carrying the West London Railway over the Great Western Railway, by means of a bridge in substitution for the present level crossing; for revising the tolls of the Great Western Railway Company, and for other purposes,' and it was in this manner, by putting forth the change of a crossing into a bridge as the prominent object, that it was hoped to gain the means to tax to an almost indefinite degree the entire traffic of the west of England. A more unworthy contrivance has perhaps hardly been recorded in the annals of a respectable English company."

Galignani gives us an account of an improved gas-apparatus for heating test-tubes, and for other laboratory purposes, the invention of M. Bertholet. It consists of six lamps and as many chimneys, which may all be placed in any way the operator may require. Each lamp is composed of three horizontal iron cylinders 15 centimetres in length, and 2½ centimetres in diameter. Each of these cylinders has eight rows of very small holes parallel to the axis, and others in its bases, besides a large one in one of them, into which the tube conveying the gas fits. One of the cylinders is lower than the other two, and when a light is applied to the holes the small blue flames issuing from them may either be kept separate or made to join in a large vertical flame. It is in the midst of this flame the test-tube is placed, resting on supports of wire which traverse the chimneys of the lamps. These chimneys are tubes bent in the form of an inverted U, and are equal in number to the lamps. The operator is not exposed to any inconvenient radiation of heat, since the chimneys, which are of sheet-iron, hardly receive any warmth during the experiment, which shows that nearly all the caloric has been absorbed by the test-tube.

Dr. Russell, the special correspondent of the *Times* in India, repeats in the most explicit manner his assertion that on an examination of the new Enfields at Allahabad, conducted by Lord Clyde and Sir William Mansfield in person, with the assistance of military officers, a considerable variation in gauge and diameter was found in the barrels of the recently arrived muskets. "Captain Butt, of Her Majesty's 79th Highlanders, an excellent officer, skilled in musketry, found," he says, "by means of a gauge made for the purpose, that there were in the muskets of his company alone variations in diameter which would affect the loading. In fact, it is patent to every officer in the army who has been engaged in the war that at least 15 per cent. of the Enfields are rendered useless after firing 10 or 12 rounds. It is quite possible that some proportion of the Enfields are injured by ill-made cartridges or unskilful loading, but the question of the existence of a variation in the barrels is not at all affected by those accidents, as the difference has been ascertained by experiment and by practical use in the field. A correspondence has taken place on the subject, in which Colonel Dixon suggests that the barrels may have been injured by the men using violence to unfix their bayonets, and so compressing the tender substance of the iron tube, and then denies that there is any difference which can be appreciable in the field, or that any officer can detect it unless he be a professional 'viewer,' and a professional 'viewer,' I dare say, we shall have to set the question at rest, coming all the way from England to Allahabad to do it. It is desirable to dispose of the matter for the sake of the makers, and for that of the service. Why should not test gauges have been furnished to the arsenals here?"

Mr. John Anderson, assistant engineer for rifled ordnance, has, it is said, taken charge of the old Lancaster shell foundry in Woolwich Arsenal to commence the manufacture of Sir W. Armstrong's guns, 48 experienced men employed in the Royal Standard gun foundry having been transferred to that department. Various other arrangements have likewise been entered into for proceeding with the manufacture of the new guns without delay.

A correspondent, after reading Mr. Forster's lecture on aluminium, which appeared in a late number, has forwarded us a copy of a paper on Ammonio-iodides of metals read by the Rev. J. B. Reade, F.R.S., at the British Association in 1857. After the reading of the paper, Dr. Lee said:—"I would also observe that with respect to the last metal alluded to in the paper, viz., aluminium, Mr. Reade seems to have a particular object in not putting the solution of iodine in direct contact with the pure metal, as in the other examples. Here he takes an oxide of the metal, alumina, and by a new process attempts to solve the problem which has so extensively occupied the attention of practical chemists in extracting the pure metal from its compounds. Mr. Reade lives upon the great basin of Kimmeridge and Oxford clay in the Vale of Aylesbury. He is, therefore, really the owner of a fortune, lying, however, under his feet, but which only requires the wand of the chemist to transform it into pure metal and current specie."

MAP OF ENGLAND AND WALES.—An exceedingly well executed map of England and Wales, mounted on canvas, coloured, varnished, and attached to a roller, has been placed within the reach of every one who has 3s. 6d. to spend on so useful an article, by Messrs. Everett and Son, of Bouverie-street, Fleet-street, London. This production deserves mention in our columns as a specimen of what the mechanical arts are doing in the way of educating the masses. The map has been most carefully reduced by Mr. J. Cooper, from the great Ordnance map of England and Wales, and the southern parts of Scotland; it has all the lighthouses, sands, and soundings round the coast accurately laid down, and showing all the railway and mail-packet communications.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated February 8, 1859.

350. J. Hosking, of Walworth Common, Oil Merchant. Improvements in the manufacture of lamps.

Dated February 24, 1859.

498. H. B. Barlow, of Manchester. Improvements in apparatus for condensing steam. A communication from F. Daina.

Dated March 2, 1859.

546. J. T. Carter, of Belfast, Flax Spinner. Improvements in machinery for crushing, bruising, and preparing flax, hemp, and other fibrous materials requiring such treatment.

Dated March 9, 1859.

609. J. Pilbrow, of Tottenham, Civil Engineer. Certain improvements in, or a new method or methods of obtaining and applying motive power, a modification of which is also applicable for pumping or forcing liquids, gases, and fluids, as also for measuring liquids, gases, and fluids.

611. Sir W. G. Armstrong, of Newcastle-on-Tyne, Civil Engineer. Improvements in rifle ordnance and its projectiles.

613. J. Erwood, of Goswell-st., Paper Stainer, and J. Skertchly, of Ashby-de-la-Zouch, Engineer. Improvements in the manufacture of glass, sand, and emery papers and cloths, and other similar articles used for like purposes.

615. J. S. Russell, of Great George-st., Westminster. Improvements in building ships and other vessels.

617. A. V. Newton, of Chancery-lane. Improved machinery for rolling horse-shoe iron. A communication from W. W. Lewis.

619. H. Fisher, of Birkenhead, Gentleman. Improvements in machinery or apparatus for cutting thin sheets of metal into strips, and for tempering sheets or strips of metal.

Dated March 10, 1859.

621. J. Yuill, of Glasgow, Ironmonger. Improvements in saddle trees.

623. H. Lodge, of Liverpool, Merchant. Improved means of protecting ships, batteries, and other constructions or buildings, from the effects of projectiles of various kinds.

Dated March 11, 1859.

625. J. C. Haddan, of Cannon-row, Westminster, Civil Engineer. Improvements in casting mortars and cannon.

627. S. Wheatcroft, of New North-road, Engineer. Improvements in the construction of goffering and rouching machines in order to render them self-registering and self-indicating.

629. F. Clarke, of Norland-sq., Gentleman. An improved mode of, and apparatus for, cutting, drying, and preparing peat to be used as fuel, or for other purposes for which it may be usefully employed.

Dated March 12, 1859.

631. J. Cunliffe, and F. Piggott, of Manchester, Manufacturers, and G. Mallinson, of Salford, Pattern Designer. Improvements in the manufacture of ornamental woven fabrics.

633. W. E. Newton, of Chancery-lane. Improvements in the manufacture of shoes and other coverings for the feet. A communication from C. Meyer.

635. J. T. Calow, of Staveley, Joiner. A compound action in cage machinery, with the apparatus connected therewith, having a perforated shield for saving life and property in the event of a rope, band, or chain breaking, or the engine-man drawing the cage too high at coal or other shafts, where slides are applicable, which said invention is also applicable to hoisting or other lifting machines.

637. J. Court, of Brompton-row, Gas Fitter. An improvement in nibs for gas burners.

639. J. Macnab, of Linlithgow, Designer. Improvements in telegraphing or signalling apparatus.

Dated March 14, 1859.

641. R. A. Brooman, of 166 Fleet-st., London, Editor of the Mechanics' Magazine and Patent Agent. An improved method of treating wool and other fibres in order to form threads. A communication from Messrs. Tavernier and Vouillon, of Paris.

643. T. Lightfoot, of Accrington, Calico Printer. Improvements in fixing colours on woven fabrics or fibrous materials.

645. C. H. Hurst, of Kennington-park. An improved wrench or spanner.

647. T. Patstone, of Birmingham, Warehouse Clerk. Improvements in shades or glasses for gas and other lamps, and in the supports of the said shades or glasses.

Dated March 15, 1859.

649. W. Langton, of Lambeth. Improvements in the manufacture of keys and wood fastenings used in constructing railways.

651. G. B. Galloway, of Newcastle-on-Tyne. Improvements upon, and in connection with, his former patents, and in the manufacture of fuel, and working steam-engines more economically.

653. W. Clark, of Chancery-lane. Improvements in the apparatus of electric lamps or lights. A communication from V. L. M. Serrin.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

656. G. Seymour, of Golden-sq., Gentleman. Improvements in making refined sugar, and making potash and soda from the residues. A communication from H. Leplay. Dated March 16, 1859.

667. J. Harris, jun., of Massachusetts. A new and useful or improved carpet-sweeper. Dated March 16, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, March* 29, 1859.)

2563. B. Predavalle. Motive power.
2599. C. Cowper. Combed fibres. A communication.
2603. H. Stott. Warping mills.
2608. E. T. Archer. Hat ventilators.
2617. C. F. Vasserot. Cooling. A communication.
2619. W. Ramscar and J. G. Scott. Fire-arms.
2621. H. Bailey. Heating razors.
2636. C. Tomlison. Taps or valves.
2637. C. Cuit. Railway breaks.
2638. W. Lea. Cocks and taps.
2639. R. A. Brooman. Dolls, statuettes, &c. A communication.
2640. H. Jordan. Navigable vessels.
2641. D. Evans. Tubular steam-boilers.
2645. H. Boden and T. Cooper. Braiding machinery.
2646. H. Gardner. Axle hub and wheel.
2649. F. A. Theroulde. Obtaining salts from marine plants.
2655. W. H. Dawes. Forge Hammers.
2663. R. A. Brooman. Cigar cases. A communication.
2668. C. Peterson Paper cartridges and paper.
2669. J. S. Nibbs. Lighting, heating, &c.
2683. J. Luis. Drawers. A communication.
2691. J. B. Booth. Spinning, &c.
2692. W. Richards. Gas meters.
2693. P. Griffiths and J. Brennand. Lubricators.
2710. G. Collier and W. Noble. Spokes for wheels.
2713. W. Parsons. Melting fat, &c.
2736. R. H. Bow. Railway chairs.
2760. G. Spiller. Knapsacks.
2764. G. E. Noone. Generating gas.
2781. H. T. Yates. Boards or sheets.
2784. W. E. Newton. Harvesting machines. A communication.
2825. J. Elder. Paddle-wheels.
2875. W. Clark. Agricultural implements. A communication.
2891. W. Clark. Telegraph cables. A communication.
2914. W. E. Dando. Lowering boats.
209. W. C. Homersham. Floating gridirons.
303. I. Clements. Curtain rings.
435. J. J. Russell. Heating and welding plates.
437. J. Seguin. Employing moving power of the tides.
526. J. Howden. Cutting metals.
544. J. Pile Floating docks.
559. J. Newcomb and J. G. Lovell. Motive power.
568. W. Score. Soap.
635. J. T. Calow. Cage machinery.
656. G. Seymour. Sugar. A communication.
667. J. Harris, jun. Carpet sweeper.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed March 25, 1859.

2161. W. Lander.
2169. J. Manning and T. Paul.
2173. T. Britt.
2216. M. Jacoby and F. R. Ensor.
2224. D. Scattergood and R. W. Smith.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

The abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 1799, 1833.
Boilers and their Furnaces, 1774.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1794, 1805, 1809, 1812, 1834, 1835.
Ships and Boats, including their fittings, 1796, 1814, 1820, 1839.
Cultivation of the Soil, including agricultural and horticultural implements and machines, 1793, 1799, 1817, 1818.
Food and Beverages, including apparatus for preparing food for men and animals. *None.*
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1775, 1781, 1782, 1783, 1785, 1788, 1792, 1800, 1801, 1815, 1825, 1826, 1827, 1831, 1832, 1845.
Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c., 1787, 1810.
Lighting, Heating, and Ventilating, 1791, 1807.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1790, 1806, 1818, 1829, 1836.
Metals, including apparatus for their manufacture, 1772, 1786, 1798, 1804, 1841, 1859.
Chemistry and Photography, 1783, 1816, 1819.
Electrical Apparatus, 1773, 1797, 1811.
Warfare, 1847.
Letter Press Printing &c., 1802, 1852.
Miscellaneous, 1776, 1777, 1778, 1779, 1780, 1784, 1792, 1795, 1803, 1808, 1812, 1813, 1821, 1822, 1823, 1824, 1828, 1830, 1837, 1838, 1840, 1842, 1844, 1846.

1772. W. Clay. *An improved manufacture of metallic hoops, bands, and other analogous articles.* Dated August 4, 1858.

This consists in making hoops, bands, &c., of steel. *Patent completed.*

1773. C. M. Archer. *Improvements in electric and submarine telegraph cables and wires.* Dated August 4, 1858.

This consists in manufacturing an elastic cylindrical spring or spiral cable, formed in continuous close rings, composed as to its inner core of the present materials, but manufactured in the form of what are known as "check springs." *Patent abandoned.*

1774. J. B. Pascoe and J. R. Thomas. *An improved method of and apparatus for feeding boilers of all steam engines with liquid without the aid of the force pump heretofore used.* Dated August 4, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1775. L. Hall. *Certain improvements in looms for weaving.* Dated August 5, 1858.

This applies to those looms in which shuttle boxes containing compartments for two or more shuttles are employed the object being to prevent by self-acting agents the injury to the warp threads which in looms of the ordinary construction is occasioned when a shuttle is thrown across the shed and against a shuttle in the opposite shuttle box. The invention consists also in a mode of constructing the drop box where the shuttle is made to act sooner on the swell, and the length of the lay bottom is reduced. The invention is not described apart from the drawings. *Patent completed.*

1776. J. Luis. *A new system of truss.* (A communication.) Dated August 5, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1777. J. Luis. *A machine for pulverizing shell, horn, and whalebone.* (A communication.) Dated August 5, 1858.

The object here is to supersede manual labour; the invention is carried into effect by an apparatus consisting of a rasper, a sifter and a mortar. It is actuated by any motive power. *Patent abandoned.*

1778. J. Luis. *A new waterproof tube without seams or girets, and in the apparatus connected therewith.* (A communication.) Dated August 5, 1858.

This comprises, 1, the union of india rubber and gutta percha with or without chemical and other ingredients as applied internally and externally to flax, hemp, cotton, or other textile hose. 2. The machinery for effecting the above process through the medium of steam or otherwise. *Patent completed.*

1779. J. Luis. *A machine for drilling and grooving the naves of wheels, and also to force the axle-box into the naves.* (A communication.) Dated August 5, 1858.

This machine is for preparing the mortices of the naves destined to receive the spokes of carriage wheels, to bore or screw out these naves, to force by pressure the axle-boxes to enter into the screw hole, and lastly, to pierce the iron if required. *Patent completed.*

1780. W. Moseley and W. S. Champness. *An improved self-filling reservoir penholder.* Dated August 5, 1858.

This consists of a tube of hard india-rubber, metal, glass, &c., terminating at the end where the pen is fixed with a fine hole. To the other end is attached a flexable chamber

Digitized by Google

made of india-rubber &c., either spherical, tubular, or any other shape. *Patent abandoned.*

1781. E. LEIGH. *Improvements in machinery or apparatus for preparing and spinning flax, wool, silk-waste, or other fibrous material.* Dated Aug. 5, 1858.

This consists in the use of two bottom rollers, and allowing the top roller to bear upon them, the pressure of the top one being exerted and regulated by weighting mechanism. *Patent completed.*

1782. J. HENDERSON. *Improvements in machinery for weaving plain or figured fabrics.* Dated Aug. 5, 1858.

This relates to a former patent, and consists in forming the cross heddle of a series of V-shaped pieces of flattened steel, in the lower part of which is a hole through which the crossing warp is passed. The upper extremities of these pieces of metal are formed into hooks by which each instrument is suspended to two horizontal rods. The stationary longitudinal wires are formed of thin pieces of flattened metal, and have at one end a groove into which is fitted a short wedge-shaped cutting blade. By this improvement the blade is held firmly in its place, and can be removed without disturbing the wire when in its working position. *Patent completed.*

1783. D. MCCUMMEN. *Improvements in the manufacture or production of paper, which improvements are also applicable in the production of alkaline and other salts.* Dated Aug. 5, 1858.

This relates to the use of marine plants, heaths, or heather, and other vegetable productions for the above purposes. *Patent completed.*

1784. C. MATHER. *Improvements in shearing machines.* Dated Aug. 5, 1858.

The object here is the removal of nap or fibre from the surface of fabric. The machine is so arranged that every portion of the face of the fabric is brought in contact with spiral cutters, one of which revolves in a direction opposite to the others. Each spiral cutter has a ledger blade, in contact with which the spiral cutter works, and the face of the fabric is lightly pressed against the ledger blade by a bed having a concave surface over which the fabric is stretched. *Patent completed.*

1785. R. A. BROOMAN. *Improvements in knitting frames.* (A communication.) Dated Aug. 5, 1858.

The object here is to construct knitting frames to produce knitted fabrics, such as stockings, gloves, &c., each of a variable width, and with a selvage. The invention is not described apart from the drawings. *Patent completed.*

1786. W. CLAY. *An improved mode of manufacturing cast steel and wrought iron into ingots and other forms.* Dated Aug. 5, 1858.

The inventor mounts the melting furnace with retorts of fire-clay, having one open and one closed end, in a horizontal position. The retorts are charged at the open ends, and the ends luted, and the flame from the adjacent fire-places is caused to play round them and melt the metal. The retorts are then tapped and the metal flows into moulds. *Patent abandoned.*

1787. W. CLAY. *Improvements in the construction of certain descriptions of bridges and girders.* Dated Aug. 5, 1858.

This consists in the use of wrought steel for such purposes. *Patent abandoned.*

1788. A. V. NEWTON. *Improvements in the manufacture of lace.* (A communication.) Dated Aug. 5, 1858.

This consists, 1, in so acting upon the bars of lace machines, through the agency of jacquard cards or wheels, that the threads of the bars are made to tie in with the bobbin threads, so that two or more independent webs or fabrics of figured and embroidered nets or laces overlaying each other, and each the width of the frame, are simultaneously produced; 2, in making pearl work by the aid of metallic wires, which serve to hold the noses of the pearls until drawn off by the progressive motion of the net beam. *Patent completed.*

1789. W. E. NEWTON. *An improved mode of ornamenting textile fabrics.* (A communication.) Dated Aug. 5, 1858.

This consists in producing ornamental designs upon lace or net, by the application of various colours principally to the ornamented parts thereof. The inventor uses mineral colours prepared from metals. *Patent abandoned.*

1790. C. BARTHELEMY. *Certain improvements in hats.* Dated Aug. 6, 1858.

This consists in the application of japan varnish to the outside of hats. *Patent abandoned.*

1791. G. H. BOVILL. *Improvements in the manufacture of gas, also in the manufacture of coke and other fuel.* Dated Aug. 6, 1858.

Here the patentee combines with retorts from which gas is collected other retorts by which only coke is produced, the gases produced in these latter retorts being consumed, and serving by their combustion to maintain the necessary temperature both in the gas retorts and in the coke ovens. *Patent completed.*

1792. F. H. STUBBS. *An improved mode of communication between the guard and engineman on locomotives or railway trains.* Dated Aug. 6, 1858.

This consists in having an extra wheel attached to the guard's van, which can be raised or lowered as required by levers. When lowered and running upon the rail this wheel carries round with it an eccentric or crank, which crank by the aid of a connecting rod works an air-pump, and by this means air is condensed into a receiving vessel, which air is used in blowing a whistle. *Patent abandoned.*

1793. C. F. KIRKMAN. *An improved mode of treating sewage for agricultural uses, and for machinery to be employed therein.* Dated Aug. 6, 1858.

This relates to machinery for grinding, amalgamating, and deodorising sewage, and removing the impurities from the liquid, so that the water only will pass away. The solid parts of the sewage will be crushed and ground up, and then pass to another part of the machine, in which it will be united with some effective deodorising disinfecting agent, and then conveyed by pumps to receivers in which the heavy sewage will deposit itself, and the impurities being removed the water will pass off in a pure state. *Patent abandoned.*

1794. S. CAREY. *An improved system of forming the permanent way of railroad transit, also common tramway, and channel or watercourse, by the means of cast-iron plates or boxes, peculiarly constructed so as to make one continuous way or channel.* Dated Aug. 6, 1858.

This consists in forming a continuous line of cast iron plates or boxes, put together side by side, or end to end, for making a channel at the sides of streets; also for forming tramways either at the edge of a roadway next the curb or in any other part of the road; likewise for forming the permanent way of railways. *Patent completed.*

1795. G. WESTON. *A washing machine.* Dated Aug. 7, 1858.

This consists of a frame of wood or iron in which a number of wooden frames are caused to slide side by side in opposite directions. *Patent completed.*

1796. G. P. LOCK. *Improvements in the composition of paints for coating iron ships, and for other useful purposes.* Dated Aug. 7, 1858.

The inventor takes for the under coating of iron ore ground in boiled linseed oil about 50 per cent., of oil and turpentine about 50 per cent., and well mixed; for the outer coatings of white lead about 40 per cent., of blue mineral or copperas about 10 per cent., and of oil and turpentine about 50 per cent., also well mixed together. *Patent abandoned.*

1797. J. WALKER. *Improvements in the manufacture of electric telegraph cables.* Dated Aug. 7, 1858.

This invention was described and illustrated at page 141, No. 9, of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

1798. J. WEBSTER. *A new or improved metallic alloy.* Dated Aug. 7, 1858.

This consists of nickel 6 parts by weight, tin plate scrap 12 parts, copper 57 parts, zinc 24 parts. *Patent abandoned.*

1799. J. SMITH, jun. *Improvements in agricultural steam-engines, and locomotive steam-engines to be used on common roads.* Dated Aug. 7, 1858.

The patentee claims, 1, supporting the boilers upon centres, or upon an axis situated in a horizontal plane, and transverse to the length of the boiler, the said centres or axes being situated below the centre of gravity of the boiler when the boiler is filled with water to the ordinary water level. Also, connecting one end of the boiler with the framing of the engine by a screw, or otherwise, so as to permit of the level of the boiler relative to the level of the framing being easily changed. 2, A mode of connecting the wheels which constitute the driving wheels when the engine is made locomotive, by a clip or clips connected with the shaft or axle, the said clip or clips being made to grip the naves of the wheels. *Patent completed.*

1800. J. LUIS. *A new twisting bobbin.* (A communication.) Dated Aug. 7, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1801. J. LUIS. *A new covering, doubling, and twisting machine.* (A communication.) Dated Aug. 7, 1858.

The inventor employs, 1, a guide, allowing the produce to pass round the cylinder as many times as there are rollers. 2, A system of arms pressing on the matter not made, placed on a bobbin, thus giving the same pressure from the beginning to the end of the bobbin. The winders of the required size, which are filled by the matter made, give an equal pressure from the beginning to end on the matter coming from the cylinder; the weight and diameter increasing at the same time. An endless cord, crossed and doubled to make two, passes into the upper and lower grooves of a three-grooved pulley, but is divided by the distance of the three grooves. A third cord having its resting point on a great roller, receives its movement from another part, and keeps the two first in equilibrium by moving in the middle groove. By this combination, the spindle fixed in the three-groove pulley experiences much less friction, and is governed by three cords instead of one. *Patent completed.*

1802. J. IMRAY. *Improvements in apparatus used in printing.* Dated Aug. 7, 1858.

These apply to presses for printing two or more impressions in register on the same sheet. The table is sufficiently long to receive the two or more forms disposed at intervals along it. The patentee holds the sheet to be printed between a tympan and a frisket, which slide with the table under the platten to receive the impression from the first form. After the first impression has been taken, the tympan and frisket containing the sheet are retained under the platten by stops, and the table is made to slide onwards till the second form is brought to its place under the platten and a second impression is taken. Thus successively any number of impressions may be taken. Finally, the table is drawn back, bringing with it the tympan and frisket containing the printed sheet. *Patent completed.*

1803. J. TAYLOR. *Improvements in the manufacture of blocks for the construction of sewers and drains.* Dated Aug. 7, 1858.

Here blocks of clay or brick earth, &c., are expressed through moulding dies of the following form: the inner surface is concave, and the sides inclined to correspond with the section of the circle or curve it is intended to produce by a series of such blocks. The outer surface of such moulded block is formed with a longitudinal rib. *Patent completed.*

1804. J. WALKER. *Improvements in machinery or apparatus for moulding or shaping metals.* Dated August 7, 1858.

This relates to collapsible core bars, such as are used for the interior surfaces of pipes. The main shell of a core bar of this kind consists of a thin cast-iron pipe cut through longitudinally from end to end. Each lip or edge of this slot is formed with a longitudinal thickened portion interiorly, to form the bearing edge surfaces for the action of a series of flat, double, incline, or wedge pieces of metal, by the action of which the necessary expansion of the core bar cylinder is produced. *Patent completed.*

1805. J. H. JOHNSON. *Improvements in apparatus for working railway brakes.* (A communication.) Dated August 7, 1858.

Here the brake blocks are connected to brake rods disposed longitudinally beneath the carriage framing, and worked by T-headed levers with the T-piece downwards the two opposite ends of the lower arms of the T-piece being connected by links with the brake rods, whilst the upright arm of the lever is connected with a main actuating rod which extends from end to end of each carriage. These actuating rods are coupled in a peculiar manner, and may be actuated from either end of the train. *Patent completed.*

1806. A. V. NEWTON. *Improvements in pianofortes.* (A communication.) Dated August 7, 1858.

This relates to a former patent, dated 1st November, 1855, and consists in so arranging certain parts as to leave the sound chamber free from obstruction, to improve the tone, and cheapen the construction of the instrument. *Patent abandoned.*

1807. J. G. PICKING and T. P. PURSSOLOVE. *An improved pressure gauge for steam, gas, or other fluids.* Dated August 9, 1858.

The inventors place a number of tubes side by side in a vertical position, and connect them together at the bottom and top alternately, so as to form a continuous pipe. Into this pipe they pour mercury until it rises in each leg to half the vertical height thereof. They fill up the remaining space in each one with water. They attach one end of this pipe to the boiler or other vessel, and to the other end of the pipe attach a graduated scale to register the pressure by the rise and fall of the mercury in the last leg. Upon the pressure being turned on it will be found that as the mercury in the first leg is depressed and forced into the next in communication, so will the mercury in every alternate leg be depressed, owing to the intervention of the water or other fluid. *Patent abandoned.*

1808. J. J. MURPHY. *Improvements in the construction of floating bodies, and in the means of supporting floating structures.* Dated August 9, 1858.

This consists of one or more inverted air-tight vessels, somewhat like a gas holder, of such a height or depth as shall allow of a permanent air space being maintained, and by which the action of the waves shall be permitted freely to communicate and operate within the said inverted vessel, and thus counteract the rolling and oscillating motion of bodies immersed in a sea-way. *Patent abandoned.*

1809. T. INGRAM. *Improvements in means or apparatus for operating railway brakes.* Dated August 9, 1858.

This invention relates to a former patent dated 20th August, 1857, and is not described apart from the drawings. *Patent completed.*

1810. H. CLAYTON. *Improvements in machinery for manufacturing bricks and tiles, and other articles of brick earth, clay, or other plastic material.* Dated August 9, 1858.

To give the alternating motions and periods of rest to the rollers applied to expressing orifices, a cam is applied to the driving shaft. This cam is arranged to move the pulleys which drive the bands, so that they may alternately gear with, or be carried round by, the upright shaft on which they are placed, the one pulley allowing the shaft to turn within it when the other pulley is held by, and carried round with the shaft. The two pulleys by two bands give motion to two screw shafts, each of which gives motion to two screw wheels, which are fixed on the axis of the rollers applied to the moulding orifices of the machine. To sustain and guide the end of the bar to which the cutter wires are strained, a bridge is fixed across the cutting frame, the upper surface of which is formed to a curve corresponding with that described by the bar. On the end of the bar a roller or truck is applied, which runs on the surface of the bridge. The wires are tightened by screw nuts, which receive within them the stems or short rods to which the ends of the wires are attached. These short rods slide through the bar in square or angular holes, which prevent their turning in the holes, and the screw threads are cut at the four angles of the short arms or stems. *Patent completed.*

1811. W. SMITH. *An improved compound for coating or insulating electric telegraph wires, and for coating other surfaces.* Dated August 9, 1858.

The compound consists of about $\frac{3}{4}$ths lbs. by weight of gutta percha, $\frac{1}{4}$th of Stockholm tar, and $\frac{1}{4}$th of resin, and is prepared by first mixing in a vessel by preference heated by steam the tar and resin and then adding the gutta percha. *Patent completed.*

1812. T. G. MESSENGER. *Improvements in the manufacture of garden engines, which are also applicable to fire or other engines.* Dated August 9, 1858.

The patentee claims, 1, the placing or arranging of the cylinder or cylinders horizontally (thereby allowing for the employment of a longer lever or handle), and also the placing or arranging of the lever or levers perpendicularly; 2, the employment of a combined jet and spreader. *Patent completed.*

1813. A. H. WILLIAMS. *Improvements in fastenings for porte-monnaies, pocket-books, and other like articles.* Dated August 9, 1858.

This consists in fitting to the tongue or flap of the cased perforated plate, or in making apertures or holes in the tongue, and in causing a stud or button pressed upon by a spring held in the side of the case to enter one or other of the perforations in the plate. *Patent abandoned.*

1814. W. E. NEWTON. *An improved method of arranging and applying magnets to counteract or compensate for the effects of local attraction on the mariner's compass.* (A communication.) Dated August 9, 1858.

This consists in the arrangement of one or more magnets in a horizontal position below or above the needle of the compass, with opposite poles horizontally in line with the vertical centre or axis on which the needle turns, and on opposite sides thereof, by which arrangement the opposite poles of the magnet or magnets are caused to act upon the needle to force it into the same direction. It also consists in applying the so arranged magnet or magnets so as to make it or them adjustable on a centre coinciding as nearly as practicable with the vertical axis on which the needle turns, so that their poles may be made to point in

Digitized by Google

any direction necessary to compensate for the local attraction, and may have their direction varied to meet any variation in the point or points of local attraction that may be produced by different cargoes, &c. Also in providing for the adjustment of the so arranged and applied magnets in a direction parallel with the axis or vertical centre on which the needle works, for increasing or diminishing the intensity of their action according to the intensity of the local attraction. *Patent completed.*

1815. W. E. NEWTON. *Improvements in machinery for drawing and twisting wool or other fibrous material.* (A communication.) Dated August 9, 1858.

This consists in a combination of tubes and drawing rollers, and a means of operating such rollers, by which the processes of drawing and twisting can be performed simultaneously, or either of these processes separately, and by which, when the two processes are combined, great convenience is afforded for varying the relative degrees of draft and twist to suit various lengths and qualities of fibre. Also in making the whole of that part of a drawing and twisting or spinning frame which carries the back drawing rollers, and the rollers or their equivalents on which the roving to be drawn and twisted or spun is contained, adjustable vertically, so as to enable the distance between the back and front drawing rollers on both sides of a double frame to be regulated according to the length of staple, and yet preserve the proper relation between the back drawing rollers and the roller or its equivalent which contains the roving. *Patent completed.*

1816. W. SPENCE. *The precipitation of purple colouring matter by chloride of calcium.* (A communication.) Dated August 9, 1858.

Here metallic oxides are used, and particularly lime in the state of a salt. The colour is extracted according to the process patented by the present patentee 1st May, 1851. To extract and separate the violet colouring principle freed from the pale red colouring matter which accompanies it, there is added to the ammoniacal coloured liquor a suitable quantity of chloride of calcium, which gives rise to a double decomposition; 1, an insoluble precipitate which contains the violet matter; and, 2, a solution more or less coloured, in which is found all the pale red matter. The precipitate is gathered on a filter, washed with hot or cold water, then dried with care, and presents the external characteristics of a light indigo. For use in dyeing it is sufficient to dilute it with water and sufficient acid to saturate the lime which is found in it. The acids which may be used are principally sulphuric and oxalic. *Patent completed.*

1817. T. PICKFORD. *Improvements in the preparation and manufacture of manure.* Dated August 10, 1858.

This consists in treating fish and marine and other animals or animal matter, seed, weed, &c., with diluted sulphuric or other acid, in pans or tanks lined with lead, and steam injected, so that it is boiled under pressure. Blood, Sombrero phosphates, or crust guano, ammoniacal liquors, bone, or gas sulphates of ammonia, gypsum, and other ingredients are used. Animal charcoal and other disinfectants are used. *Patent abandoned.*

1818. A. BARCHOU. *Improvements in the mode of fastening the soles and heels of boots and shoes.* (A communication.) Dated August 10, 1858.

This consists in joining the upper leather of boots and shoes to the exterior and interior soles by a threaded nail or spindle. *Patent completed.*

1819. M. HENRY. *Improvements in the manufacture or production of saltpetre, and the preparation of materials for the purpose.* (A communication.) Dated August 10, 1858.

Here nitrate of soda is treated with caustic potassa direct. *Patent abandoned.*

1820. R. H. COLLYER. *An improved coating composition to protect vessels from marine animal and vegetable substances.* Dated August 10, 1858.

This consists in the application of the metals zinc, tin, and lead, or their oxides, singly or in combination, added to any adhesive substance. *Patent completed.*

1821. F. HAECK. *Improvements in the construction of cocks, taps, or valves.* Dated August 10, 1858.

The barrel of the tap, &c., is formed with a conical or spherical seat covered by a layer of india-rubber, &c., and the closing of the passage therethrough is effected by suitable closing means, and the inner end of this closing means is formed with a disc which fits a cylindrical portion of the barrel within which it is capable of traversing. This disc is perforated near its edge with a series of holes, which together are of the area of the passage through the seat. The other end of this closing means is formed with a stem by which it is operated for closing or opening, and the stem may be formed with a screw to turn in a female screw formed in a fixed part of the tap. The parts of the tap may be made of porcelain, or metal. *Patent completed.*

1822. M. MOSES. *Improvements applicable to umbrella and parasol sticks.* Dated August 10, 1858.

The object here is to give a greater command over the umbrella or parasol. It consists in applying to the central stick a stop-piece or rest, against which the hand employed to grasp the stick will bear, and so relieve the strain on the muscles of the arm or hand. *Patent completed.*

1823. J. H. WHITEHEAD. *Improvements in the manufacture of woollen bags.* Dated August 10, 1858.

Here woollen yarn is employed for weaving tubular fabrics of the diameters desired, and to close the end of each bag, the same is done either in the loom, by throwing in shoots of woollen weft, so as to weave the warps into one fabric, or the tubular fabrics are sewed across by the hand. The bags are then to be milled, by which the ends of each bag will become felted together. *Patent abandoned.*

1824. J. T. PITMAN. *An improved mode of operating apparatus for lifting and pressing.* (A communication.) Dated Aug. 10, 1858.

This consists in the employment of mechanical agents, so that when little or no power is required the pressure may be effected, and the apparatus may be brought to the lifting point with great rapidity by one device; and when more power is needed than is consistent with such rapidity, the increased power is obtained by another device. The main agent is the screw fitted to play into a female screw running the entire length of a revolving cylinder or nut. *Patent completed.*

1825. S. F. COTTAM. *Improvements in machinery for doubling cotton and other yarns or threads.* Dated August 11, 1858.

This consists in so constructing doubling frames that as soon as the yarn or thread breaks the top roller ceases to revolve. *Patent completed.*

1826. R. C. GIST. *Improvements in knitting machines.* (A communication.) Dated August 11, 1858.

The object here is to knit plain tubes or cylinders continuously, and it is designed to operate with the number of threads simultaneously. It consists of a revolving cylinder carrying the needles, sinkers, and fabric, and a stationary cylinder sustaining the cams by which the needles and sinkers are worked. The yarns are laid by the carriers just before the needles attain their highest elevation; they are then carried in loops between the needles by the sinkers, and are caught under the barbs of the descending needles, which are closed by the bevelled teeth of the presser wheels. The needles pass through the old loops with the loops last formed beneath their barbs, and are elevated by another cam, and the operation is repeated with as many threads as there are cams. The number of yarns thus laid in at each revolution is limited only by the size of the machine. The knitted fabric is guided by an expanding plate, and is wound on a roller by suitable gearing. *Patent completed.*

1827 J. B. JOYCE, J. CURE, J. BOYCE, and J. CLOUGH. *Improvements in machinery or apparatus for combing wool and other fibrous materials.* Dated Aug. 11, 1858.

These consist in the use of a cam, &c., for bringing the swift towards the cam. This cam has a continuous rotary motion, and brings the swift up to the feed rollers of the machine, detaining it there while the combs which are placed on the swift are filled. The cam then pushes the swift on the slides to the travelling comb, and detains it there while the combs which are on the swift are emptied. This cam is worked by power; also, the swift is worked by the same means while at the feed rollers, but not while it is at the travelling comb, being reversed by hand. *Patent abandoned.*

1828. J. G. APPOLD. *Improvements in the manufacture of wire ropes or cables.* Dated August 11, 1858.

This consists in protecting telegraph cables by two sets of wire strands laid round the internal core in opposite directions. *Patent abandoned.*

1829. R. A. BROOMAN. *Improvements in time-keepers.* (A communication.) Dated August 11, 1858.

This relates to the regulation of time-keepers put in motion by weights or springs, and consists in the employment of pendulums, each pendulum being formed of two horizontal, or nearly horizontal, arms, carrying discs, each arm being formed of a metal or other material of different expansibility to the other, and the two being so combined that, as their lengths are caused to vary by variations of temperature, the angles which they form with each other, or with a vertical line, shall also vary so that the distance of their common centre of gravity below the point of suspension may be constant, and, therefore, the times of oscillation of the pendulum be constant. The discs may be furnished with indicators to indicate the variations in the dilatations of the arms, and the corresponding variations in the angles made by them. *Patent abandoned.*

1830. E. TAMBERLICK. *Improvements in apparatus used for exhibiting advertisements.* Dated August 11, 1858.

This consists in the employment of a hollow octagonal iron column made of framework and glazed on all its faces, and on the glass advertisements are written. Within the column lamps are placed, which render the advertisements legible at night. *Patent abandoned.*

1831. W. MECKEL. *Improvements in textile fabrics.* Dated August 12, 1858.

This has reference to woollen and union stuffs, and consists in producing a woven pattern upon the face of the fabric resembling the ordinary quilting, and forming the groundwork of the fabric. The inventor causes an additional weft to be employed during the weaving, for raising or doubling the surface in such parts of the material as are necessary for producing the desired effect. *Patent abandoned.*

1832. W. KNOWLES. *Improvements in certain parts of machinery used in preparing and spinning cotton and other fibrous materials.* Dated August 12, 1858.

This consists in a mode of weighting the top rollers of machines used in preparing and spinning cotton, &c., by the application of rotary weights bearing upon the pivots, or upon the spaces between the bosses of the top rollers; also, in the application of intermediate rollers between the top rollers and the weighted rollers. *Patent completed.*

1833. J. SCOTT and A. MARTINUCCI. *An improved steam-engine.* Dated August 12, 1858.

This consists in dispensing with the ordinary steam cylinders, and their valves and pumps. The engine consists of a solid cylindrical piece of metal, having recesses bored into it for inserting the valves, and for admitting steam. The centre of the cylinder is bored out to receive a solid ram, and the lower end of one side and the top end of the opposite side of the bore has a steam space cut therein, corresponding with similar steam spaces in the ram, so as to receive a reciprocating movement by the action of the steam, first on one side and then on the other, and so on continuously, without requiring condensation, and which may be prevented by raising the temperature of the metal composing the body of the engine. The boilers, steam pipes, and connections may be similar to those in ordinary use. *Patent abandoned.*

1834. G. HOUGHTON. *An improvement or improvements in saddles.* Dated August 12, 1858.

The patentee claims giving elasticity to the seats of saddles by springs made of plates or strips of metal, the said springs having certain forms represented in the drawings, and being so applied as to keep the webs or other material constituting the seat of the saddle in a state of tension, whether the said springs be applied to the anterior or posterior part of the saddle. *Patent completed.*

1835. J. H. M MAISSIAT. *Improvements in wheels.* Dated August 12, 1858.

Instead of the rigid radii or spokes of the wheels, the patentee interposes between the axle and the ground any elastic material that is susceptible of changing its form in a notable degree by elasticity. *Patent completed.*

1836. G. METZLER and J. WADDELL. *Improvements in the construction and formation of valve musical instruments.* Dated August 12, 1858.

Here the patentees have adopted an arrangement of tubing. They have also adopted an arrangement of the valves, in which the note-and-half tubing attached to the third valve is made a part of the "pitch" tubing of the instrument, the valve being made so as to allow the current of air to pass through this note-and-half tubing in all the open notes. The position of the bells of their instrument is similar to cornets, trumpets, trombones, &c., so that the instruments are placed or held across, or parallel to the body of the performer, thereby bringing the weight nearer the performer. *Patent completed.*

1837. J. FOGG. *Improvements in pressure guages.* Dated August 12, 1858.

Instead of allowing the fluid, the pressure or weight of which is to be indicated, to come into direct contact with the mercury, &c., the patentee interposes a moveable metal piston between such pressure or weight and the fluid used for indicating, the areas or superficies of the ends or other parts of such plug being made of such proportion to one another as it may be desired to decrease or increase the length or height of the indicating column below or above its natural height. There are various modifications included. *Patent completed.*

1838. R. BAXENDALE. *Improvements in brushes, mops, or apparatus for washing and cleaning.* Dated August 12, 1858.

The inventor makes the head of the brush hollow, and attaches to it a tube, through which liquid passes, the flow being regulated by a valve. *Patent abandoned.*

1839. A. J. PATERSON. *An improvement in propelling ships and vessels.* Dated August 12, 1858.

This refers to a former patent dated 2nd May, 1857, which consists in building the ship, fore and aft, with one or more cones or frustrums of cones, instead of the ordinary bows or stern. The patentee mounts screw blades upon a conical frame corresponding to the shape of the bows or stern, and causes this frame and screws to revolve round the fixed cones. Now, the present invention consists in causing the blades to revolve round the conical bow or stern, instead of the conical bow or stern revolving with the screw blades. *Patent completed.*

1840. R. JOBSON. *Improvements in apparatus used when making moulds for casting shells and other articles.* Dated August 12, 1858.

This invention is described and illustrated on another page of this Number. *Patent completed.*

1841. E. SMITH. *An improvement in puddling iron.* Dated August 12, 1858.

This consists in introducing streams of air between the sides and ends of a puddling furnace and the protecting materials (sometimes called "fettling") with which the furnace is lined, by which the plates, sides, and ends, as well as the lining materials are preserved. *Patent abandoned.*

1842. R. JOBSON. *Improvements in apparatus for supplying water to axletree boxes and other journal bearings to lubricate the same.* Dated August 12, 1858.

This consists in combining a water cistern and an axletree box, or the bearing of a journal, with the water passages or pipes so that the water may circulate from the axletree or journal to the water vessel, and from the water vessel to the axletree or journal. The water vessel may form part of the box or bearing, or be separate and at a distance therefrom. *Patent completed.*

1843. H. SMITH and T. W. ASHBY. *Improvements applicable to haymaking machines, whereby such machines are rendered useful for other agricultural purposes.* Dated August 12, 1858.

This relates, 1, to a mode of mounting the tine cylinders or barrels of haymaking machines, and of arranging the gearing for actuating the same, the chief object being to obtain the reverse rotary motion of the tine cylinders (when desired) in a simple and convenient manner. 2, to the application to the teeth or tines of haymaking machines of moveable bars provided with sharp cutting edges, and also short teeth or tines for extending the use of the implement and enabling it to cut off the tops of thistles or weeds, and also of breaking up light clods of earth or manure. The invention is not described in detail apart from the drawings. *Patent completed.*

1844. R. JOBSON. *Improvements in apparatus for crushing and sifting.* Dated August 12, 1858.

This invention will be described and illustrated in our next Number. *Patent completed*

1845. W. B. NORTCLIFFE. *An improvement in dyeing woollen, worsted, cotton, silk, linen, and other textile fabrics and fibrous substances.* Dated August 12, 1858.

This consists in the use of nitrate of copper in combination with the extracts of logwood and fustic, with or without terra japonica, as a first process, and in the use of chromate of potash as a finishing process. *Patent completed.*

1846. L. AUTRA. *Improved apparatuses for exhibiting advertisements.* Dated August 13, 1858.

This consists in fitting up the fronts of houses with, or in placing against walls, frames containing glass, each frame being set at an angle, so as to obtain an extended surface within a comparatively small space, and in writing thereon the announcement desired to be published. *Patent abandoned.*

1847. F. J. MANCEAUX. *Improvements in stocks for fire-arms.* Dated August 13, 1858.

This invention was described and illustrated at page 188 No. 12, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, APRIL 8, 1859.

THE LONDON MECHANICS' INSTITUTION.

THE remarks made in our last number on the founding of this Institution have elicited many communications from men who love truth and justice, but neither has Lord Brougham, nor have those gentlemen who now manage the Institution's affairs, and who servilely sanction the noble lord's misrepresentation, offered any rejoinder to them. Mr. Hodgskin, who was associated with Mr. Robertson in the founding of it, and who still lives to vindicate the truth, writes as follows :—

"TO THE EDITORS OF THE 'MECHANICS' MAGAZINE.'

"16 Claremont Row, Islington, N.
April 2, 1859.

"GENTLEMEN,—Allow me to return you my thanks for your article last week on the London Mechanics' Institution, in which you do justice to the parties especially concerned in originating and founding the Institution. If this have now a money value, and can unlock the purses of the nobility and the gentry to bestow on Lord Brougham what would be a fortune to a person, not richly endowed by the State like the noble Lord—if it call forth the laudation of the noble Earls, Right Rev. Bishops, and Right Hon. Gentlemen, (though I remember the time when numerous members of these classes scowled on the individuals who really tried to promote intellectual improvement and independence, as contradistinguished from mental drilling into peculiar habits of thought, and when Right Rev. Gentlemen preached against Mechanics' Institutes,)—if it be a meritorious step in social progress, now calling forth public approbation—and I see to subscribe to an Institute is now proposed as a means of enfranchisement — then nothing can be clearer than the propriety and justice of informing the public who were the actual originators and founders of the London Mechanics' Institution. I rejoice much to see a due appreciation of such institutions in high quarters, and I also rejoice to see them now forming a large portion of the intellectual life of this noble community; for the more they are honoured and praised, the greater will be the recompense of those who, neither wedded to past prejudices nor seeking meretricious popularity, most contributed to originate and promote them. Let me, therefore, remind you that prior to the London Mechanics' Institute being established, the WORKMEN of Glasgow had proposed to establish such an Institute for themselves, and you will find the evidence of the fact in the early columns of your Magazine. They, therefore, deserve the praise of first endeavouring to establish such an institution in their own behalf. But their exertions in no degree detract from the merit of those who started the idea of founding a great institute in London by an appeal to the mechanics' and the public, and carried it into execution with a success not to be surpassed by any similar attempt in modern times. You, gentlemen, have, in your notice of this movement, done justice to the late Mr. Robertson, to Dr. Birkbeck, and to myself; and there are many others, some gone and some yet left, who deserve much praise for having contributed to what is now acknowledged to be a good work.

"I must now say that with reference to Lord Brougham, you have, I think, misunderstood the empathic *we* in his letter to which you refer. I wrote a note to his Lordship a short time ago, asking him if he had seen the false statement in the *Times* on this subject, to which I directed attention in other journals when it occurred. The answer which Lord Brougham gave to my question will, I think, prove both that the *Times*—I do not say the unknown writer in that journal, for it is totally distinct from its contributors—knew that Lord Brougham was not the founder of the London Mechanics' Institute, and that by his late letter from Cannes, read at the meeting, he does not mean to make any such claim. I have no hesitation in sending you an extract from his Lordship's answer for publication—though I have not asked his permission—because it concerns a public matter and his personal honour :—

"'Lord Brougham presents his compliments to Mr. Hodgskin, and in answer to his letter which he received last night, he has to state that he cannot say whether he saw the paper published four or five weeks ago, in which, according to Mr. H., some one has done Lord B. the *unmerited* honour of mentioning him as the founder of the London Mechanics' Institute. He has been often so represented, and he has *always contradicted* it, and he will cause to be copied and sent to Mr. H. a speech on the subject which he made in 1835, and which has been repeatedly published. He has continually declared Dr. Birkbeck to be the founder, and has added that he had coadjutors, of whom Lord B. has represented himself to be one, as he well might.'

"The extract promised by his Lordship was from Vol. III, page 582, of Lord Brougham's speeches, and as it stated only at greater length the substance of the above extract I shall not quote it. I may, however, add that his Lordship informed me that he made a like statement in a tract which he published in 1845. The whole reading world therefore knew several years ago that Lord Brougham disclaimed the honour which the *Times* attributed to him a few months since to obtain relief from a pecuniary difficulty incurred for the London Mechanics' Institute. The noble lord himself having present to his mind these circumstances, and knowing that were he to make such a claim it would be at once questioned, did not mean—as you imply—that he, in conjunction with Dr. Birkbeck, founded the Institute.—I had written thus much and more before the letter of the noble lord, as published in the *Times* this morning, fell under my notice, and in this version of his epistle from Cannes I find to my satisfaction that the *we* is converted into *he*, so that the true reading is 'he (Dr. Birkbeck) both founded and endowed the Institute.' How far this is correct you have already explained. I have only to add, that so far as Lord Brougham is concerned his personal disclaimer of the honour which the *Times* thrust upon him is complete.

"I remain, Gentlemen, your obedient servant,
"THOMAS HODGSKIN."

We are glad to find, for Lord Brougham's sake, that the disclaimer made in respect to himself was complete, and that the apparent intrusion of a claim on his own account in the end of the sentence quoted from his letter last week was but a misprint. But this, of course, leaves the injustice done by him to the memory of Mr. Robertson as flagrant and as indefensible as ever.

And let us now express a plain sentiment or two with respect to this London Mechanics' Institution. The intention of its real founder, and that of his friend Mr. Hodgskin, was that it should really be what its name implies—viz., an institute for mechanics. But is it that now? Has it been that since the first year of its foundation? If it had been, would its officers have been cringing, and petitioning, and begging, hat in hand, for years past, from princes and noblemen for the means of keeping it in existence? Nay, worse than that, would they have been miserably lending themselves, not only to these questionable proceedings, but also to the propagation of a statement which five minutes' perusal of an accessible book (if that were necessary) would have shown them to be utterly false? We put these questions confidently, and would wish to see them answered. It grieves us to have to express ourselves in these terms on this subject. But it is our clear duty to do it. We cannot turn from the task with the facts of the case present to our mind.

Last week we showed that Mr. Robertson was, and that Dr. Birkbeck was not, the founder of the Institution. This week we have the testimony of Mr. Hodgskin, who knew all about it from the first, to that effect. But we have more than that. We have the distinct disclaimer of Dr. Birkbeck himself on the subject. In his Inaugural Address, delivered on the 20th of February, 1824, at the opening of the Institution, the Doctor spoke as follows :—

"For myself, who, although *not the originator of this Institution*, took the earliest counsel with its earliest effectual projectors, I can boldly declare, that the scientific cultivation of the mind of the mechanic was, and still continues to be, *my only object*. For my friends, Mr. Robertson and Mr. Hodgskin, your original temporary secretaries, who first gave currency to the plan, and were the powerful means of organizing our first public movements, I can with equal confidence answer. But what need of any voucher here for them? They are always before you. The MECHANICS' MAGAZINE, the most valuable gift which the hand of Science ever yet offered to the artizan, of which they are the intelligent editors, carries along with it incontestible evidence of the inflexible resolution with which they can pursue their sole objects—your amelioration and your instruction. For several individuals who took an active part in the public proceedings, and for the committee to whom you have intrusted the management of your concerns, I can, without hesitation, make a similar avowal."

Does Lord Brougham, do the present officers of the Institution, need further proof of the justice of our course, or of the injustice of their own?

But we claim for Mr. Robertson more than the honour of founding the Institution. We contend that to him is due the further honour of endeavouring to secure for it a proper basis, of resisting the measures which have reduced it to beggary, and of prophesying its present disgrace when he found such resistance hopeless. It is only necessary to turn to the first two volumes of this Magazine for the most satisfactory proofs that he laboured hard, and, despite bitter hostility, to preserve its purity as a *Mechanics'* Institute, and to avoid that very debt which has ruined it. In a supplement to the second volume of the Magazine, written expressly upon this subject, he speaks with a degree of grief and anger which he only could be expected to feel. He says :—

The Anniversary which the Managers and their friends consider a fit subject for convivial celebration, brings to the Editor's mind only cause of sorrow for principles abandoned, laws and promises broken, and great interests lamentably sacrificed. The Institution was founded for the benefit of the journeymen Mechanics of London chiefly, who showed, by the numbers in which they flocked to its first meetings, that they were fully sensible of the important benefits which it promised to procure for them; but so slowly and imperfectly have the plans laid down been followed, and so little has the year produced, suited to the wants and taste of the journeyman mechanic, that the number of this class now enrolled as members has dwindled to a few hundreds, of whom a large proportion are new intrants, who, if we may judge from the past, have entered only to acquire that experience of empty professions which has disappointed and driven away their predecessors. The number of members altogether is small, and certainly not more than *one half* are of that class of persons for whose special benefit the Institution was founded. The Institution was established, too, on the condition that the mechanics themselves should have, in the proportion of two-thirds, the preponderance in the management of its affairs; but that condition, as we have seen, has been shamefully violated. It was provided, also, that the Institution should rest on the principle of self-support and exertion. The mechanics of London would have disdained to seek advantage from it on any other. But, though the rate of contribution to the London Mechanics' Institution is higher than to any similar Institution in the kingdom, it cannot (it is believed) be said, that one penny has yet been paid for lecturers or teachers. The Managers have proceeded on a system of begging for gratuitous instruction, wholly inconsistent with that spirit of independence which breathed in the first resolutions of the Society, and in our humble opinion, most injurious to the real interests of the working classes. Who can doubt that it is partly owing to an honourable repugnance to instruction on such terms, that so few mechanics are now to be found in the list of members?

Have we not here the vital defects of all so-called Mechanics' Institutes laid bare? Are they frequented mainly by mechanics? Certainly not. If they were, would they be in the languid and almost eleemosynary condition in which too many of them now are? Most emphatically we say no. Very many, if not the great bulk, of the Institutions thus designated are in the main mere places of amusement—dancing-schools, singing-rooms, amateur theatres, and so forth, carried on for the amusement of mere lads and girls, who do not, in the majority of cases, belong to mechanics at all. We are not now speaking against such places of amusement. They may be very useful things in their way. But to disgrace the name

Digitized by Google

of mechanics by placing it upon such places is to insult the class. We have no desire to flatter mechanics; we should not know how to do it if we had. But we do say that they, as a class, respect themselves far too much to beg for anything—least of all for the means of acquiring knowledge; and in the name of the mechanics of this country we call upon the promoters of Institutions everywhere either to make them self-sustaining—no matter how humble that may render them—or else to wipe the name "Mechanics' Institution" off them altogether.

GUNPOWDER MANUFACTORIES.

THE fearful explosion at the Hounslow Gunpowder Mills will necessarily for a while draw men's attention to the consideration of the causes of such disasters, and the more philosophic and profitable means of their prevention. We have had enough of these accidents to convince us that gunpowder is a chemical combination of an extremely treacherous nature. Although not so uncertain as gun-cotton and fulminating silver it is, from the difficulty of defining to what lengths it may be trusted, of the same coquettish family. Gun-cotton, it has been proved in the making of rockets, may be rammed by a succession of gentle taps, or by the whole force of hydraulic pressure some nine thousand nine hundred and ninety-nine times with perfect impunity, and then a child shall drop a mere rod upon it and cause the loss of many lives. Fulminating silver may be stirred with impunity two or three times a-day in a wooden bowl with a wooden stick for a period of some ten or fifteen years, and yet this simple act shall at some other time scatter into space a large factory, spread dismay throughout Bond-street and Piccadilly, and strike the ingenious inventor of wire-cartridges a corpse. With gunpowder, copper as a metal has, from the time of Roger Bacon, been supposed to be friendly, and men have not doubted that the former would patiently submit to be knocked about by the latter with the greatest unconcern; yet after such a fact has been almost universally accepted as beyond dispute, experiments in France and Austria incontestably prove that under special circumstances copper is as liable to produce its ignition as iron. Indeed, at the accident at Hatton, about a year ago, a spark was seen to escape from the copper tool used by one of the men. And now we have iron rollers substituted at the Hounslow Powder Mills in lieu of stone, as iron is considered to ensure an additional safety from accidents.

When we visited the works on Thursday we found the pressing-house, or rather the site where it had stood, bearing every evidence that it was upon this spot that the explosion first took place, the greatest corroboration being in the fact that the hydraulic press in the centre of the building yet remained almost uninjured. Not only that the accident originated here, but that the press itself was the cause of it, we feel fully convinced. The four uprights of the press were still standing, somewhat, however, out of the perpendicular. The bottom was nearly perfect, but the whole of the top had been blown away. This would be just the effect which might have been anticipated from an explosion taking place within the press. It acted in some wise as a huge piece of ordnance, scattering destruction around, but leaving itself intact.

Now, does not extreme pressure necessarily involve friction of particles, and does not friction of particles, under certain circumstances, and in countless instances produce ignition? If the reply is in the affirmative, what is there in the nature of sulphur, or charcoal, or saltpetre to exempt them from a well-ascertained law? We believe we are not alone in pointing with suspicion to this machinery. Very well-grounded fears respecting its danger have been openly expressed by the best informed men upon the works; and if we are not misinformed, so strong was this feeling during the period of its construction that the foreman of the works, after respectfully protesting against its adoption, resigned his appointment rather than run the risk he saw in its use.

Fear does not, however, appear to exercise much sway over the men who work in these dangerous trades. Eight men were killed on the Wednesday and more than eighty had, directly or indirectly, offered to supply their places before even their mangled remains were consigned to the grave. Surely, then, the inducement must be great; the pay must be liberal, and the hours short. If two shillings and twopence a-day be an equivalent for the risk, this the "black men"—the men who must go with a "blow"—receive regularly and faithfully. And here a most important consideration presents itself. Have we any right to tempt honest men, even for fifty times that amount, to risk their lives in such an avocation? Surely we have convicts enough doing nothing—or less than nothing—who might be employed in such pursuits, and who might then be paid for their time; for no one would grudge even the greatest malefactor 2s. 2d. a-day when it was known that his body was liable to be rent into fragments and scattered to the four quarters of the globe at a moment's notice. The question whether Hounslow is *now* a proper locality for the carrying on of so dangerous a trade must shortly force itself upon the attention of the Legislature; and we shall not be surprised to hear that meetings are called and attended by the principal landowners and others for some five miles round to take into consideration a matter which so seriously affects the interests of their property, and the consequences resulting from fright and alarm which so many of their relatives and tenants are now suffering and may suffer for years.

PATENTS FOR INVENTIONS COMMUNICATED FROM ABROAD.

WE have occasionally met with persons who are not a little astonished at the frequency with which the names of certain individuals appear in the official lists of patentees; and who consider that those individuals must certainly possess prodigious inventive powers. Such persons further suppose that the patentee invariably has a personal interest in, if he be not the proprietor of, the patent for which he applies. As one of the Editors of this Magazine, Mr. R. A. Brooman, is the patentee of some scores of inventions annually, we have ourselves experienced the disadvantages of the mistakes which persons make in this respect. As it is our invariable practice never to have a property in inventions, under any circumstances—in order that we may be perfectly unbiassed in the opinions which we form professionally upon the numerous inventions that are daily brought before us—we think it desirable to explain how it is that one of us so frequently appears before the public as a patentee.

The cause of this is simply that, in the course of our practice as patent-agents—a practice which has been pursued in this office for nearly forty years—we are brought into communication with numerous foreign inventors resident in various parts of the world; and, beside these, we are, of course, in communication also with many English inventors resident abroad. Now, in order that these two classes of inventors—foreigners, and subjects of Her Majesty residing in foreign parts—may obtain patents in Great Britain for their inventions, they must either execute declarations, &c., in English abroad, or come to England themselves, or employ a reliable agent to secure their patents for them. The latter is the course most usually preferred, as might be expected; and it is solely in the capacity of confidential agent to such inventors that Mr. Brooman applies for so many patents annually. It will be observed that wherever his name appears, the title of the invention is followed by the words "A communication," which imply that the invention is not his own, but that of a client residing abroad. The patent is, it is true, the property of the patentee when granted, but it is his only with the understanding that as soon as it is obtained it shall be duly and formally assigned to the true proprietor, as is invariably done. These remarks apply, of course, not to our own case only, but to all cases in which inventions are communicated from an inventor residing abroad to another person.

From this statement it will be seen that we have no more real interest in patents in which the name of Mr. Brooman appears than we have in those patents which, as patent-agents, we obtain daily for British inventors. Nor have we, as we have already intimated, an interest in any invention or inventions whatever. We are, therefore, at all times perfectly free to form opinions, and pronounce decisions, upon any and every invention which may be brought before us. To all of them we apply the large experience of many years—this we may surely say without ostentation; to none of them do we apply any kind of interest or prejudice whatever.

We have thought it desirable to make these remarks thus prominently in order to prevent misapprehension on the part of our friends, clients, and subscribers.

THE CIVIL SERVICE SUPERANNUATION BILL.

THE withdrawal of the compulsory retirement clause of the Civil Service Superannuation Bill at the eleventh hour—for although the reports in the morning papers differ, it seems to be withdrawn—deprives that measure of a most important feature. We complained some little time since that there were many ancient officers in receipt of salaries—and some of very large salaries—on the list of civil servants who had not performed a day's duty for years. These men, who have not scrupled to draw unjustly the public monies, are to be permitted to continue their dishonest practices, whilst their under-paid subordinates are to be compelled to submit still further to the wrongs under which they have hitherto suffered.

This ought not to be so; the question of compulsory retirement at sixty-five years of age had been fully discussed, and there was no doubt about the justice of the proposition. Why, then, was the clause eliminated from the Bill? From no other cause than that the influence of a few pertinacious friends of the old fogies, who happened to have seats in Parliament, baffled the somewhat simple-minded Sir Stafford Northcote and the more wily Mr. Wilson. In the new House of Commons we trust the compulsory provision may obtain more favour.

THE ENFIELD RIFLE.

THERE have been numerous letters in the *Times* this week respecting the statements of Dr. Russell, mentioned in our gossip of last week. Mr. J. D. Goodman, the chairman of the Birmingham small arms' trade, says:—

"Your correspondent's own statement sufficiently explains the matter. It is clear that the officers by whom the examination was made had no proper gauge."

Digitized by Google

Again he says:

"It is clear the ammunition was at fault. The barrels did not become smaller, but they became foul. The correct size of the bore is ·577 inch. Before a barrel leaves the barrel-maker's hands, it is tested by a plug of this size. As the same barrel passes through the hands of the various workmen in the subsequent stages of making up the gun, the ·577 plug is again and again applied, not by workmen only, but by viewers repeatedly. The plugs used are constantly compared with delicately-adjusted standards, so that error is impossible. I don't know how many guns there are now in store, but if there are 50,000, I will pledge the reputation of the gunmakers of Birmingham that not one single barrel, if uninjured, shall reject the ·577 plugs."

The next writer is a correspondent signing himself "H," whose theory is:—

"That the bore of the rifles in question was of the proper size when they left the hands of the manufacturers, but they have been so injured by use as to prevent the bullets from being rammed down. If the above conclusions are correct," he adds, "it is evident that, unless the barrels are left much thicker, or some method devised for making them of cast steel, instead of soft iron, the Enfield rifles can never be relied upon to stand the hard usage they must necessarily receive in the hands of soldiers on actual service."

The next is Mr. W. Greener, who volunteers an explanation which is purely fantastical, and, therefore, very characteristic of its author. His suggestion is, that if you fire an Enfield rifle several times with a tight ring of iron around the barrel, the bore will become contracted within the ring, and the ring will become loose. Then we have:—

"The bayonet socket at Allahabad is this ring. Ten or fifteen rounds have produced an imperceptible contraction of the barrel by its yielding in the weakest point—viz., 'the three grooves which are now narrowed,' and the bore less, and hence the defect. . . . An additional cause will be found in the enormous vibration to which the bayonet blade is subjected by the adjacent concussion travelling down to the socket with a 'lever's' power, exercising a force on the comparative weaker tube equal to the effect produced. The remedy for this is better metal or more of it."

Thus this oracle.

Next we have Sir John Scott Lillie, who rails at the "wiseacres of the War Department," and recommends improved cartridges and breech-loading arms as a cure for the Enfield rifle.

Finally we have a letter from Mr. Samuel Aspinwall Goddard (who with another gentleman invented two very important parts of the Armstrong gun). Mr. Goddard believes the barrels all to be of a proper gauge, but to be liable to rapid fouling. He then tells us that during the war in the Crimea he submitted an invention for cleaning rifle barrels on the field. It was tried at Enfield, and, as he supposed, with complete success. On the very day that he was at Enfield copies of the reports were received there, made by the four Brigadiers in the Crimea, by order, on the subject of the clogging of the rifles, thus showing the extreme importance attached to it.

"The mode of cleaning suggested by me," he says, "was very simple, and thoroughly effective. It occupied no appreciable time, it could be adopted without interfering with any other arrangements and with no inconvenience to the soldier, and it did not require that any other means which had been adopted, or which might be adopted, should be dispensed with. It was inexpensive and certain, and not only was the barrel completely cleaned, but was found not to clog afterwards under about 50 rounds. I believe the trial was favourably reported upon, but some time after I was informed that 'other means had been taken for effecting the object.' What those means were I never knew, nor whether any of my suggestions had been acted upon."

THE CULTIVATION OF FLAX.

The appearance of a pamphlet just issued by the National Flax Company* has recalled our attention to a movement which appears to us to deserve the support of the public, both on patriotic and on commercial grounds. The object of the Company is to prepare flax and other fibrous substances for manufacturing purposes; and also to promote, by certain well-defined measures, the more general growth of the home plant, in order thereby to avoid those fluctuations in the supply which are so injurious to manufactures and commerce. We have not space just now to enter at any length into this subject; we will content ourselves for the present with adding a sentence or two from the Company's prospectus and pamphlet. "Rightly estimating the evils existing in this branch of productive industry," says the prospectus, "the Company propose in the first instance to immediately relieve the grower from this incubus upon his labour by establishing in various available localities throughout the United Kingdom proper rettories, which shall supersede the old plan of preparing flax for the spinner, whereby the processes of steeping, drying, and scutching, are rendered so tedious, uncertain, and costly; in a word, both landholders and manufacturers will, by the patented processes of this Company, be saved a vast outlay of capital and an unnecessary expenditure of time, while the injury to the texture and colour of the fibre, inevitable on the modes of drying, whether by means of stoves, heated rooms, or atmospheric exposure, now practised both at home and on the Continent, being obviated, the commercial and trade value of the article through every phase of its manufacture will be intrinsically enhanced." "By the machinery of Mr. Cator," says the pamphlet, "the flax, after being lifted out of the water, is passed at once in a continuous course through pressing rollers, and round cylinders heated by steam (being pressed against these cylinders by small carrying rollers), into fluted rollers, whence it is conveyed by hand all ready dried and broken, to be scutched. Thus the operation between the water and scutching is performed in less than a quarter of an hour. One machine is capable of drying sufficient flax to produce half a ton of fibre and a quarter of a ton of tow in ten hours. The advantages to be gained are evident, viz.:—The saving of time, labour, and material (say in value from £5 to £10 per ton of fibre), the certainty and simplicity of the process, entire independence of the weather, ability to work throughout the year without interruption, reduction of the present complex system into one easily understood, and an addition of quality to the fibre without diminution of strength." The control of this Company is in very good hands. We shall probably give a description of the machinery adopted by it on an early occasion.

* Explanatory Details, Opinions of the London Press, and Commercial Arguments in favour of the System proposed to be adopted for the Encouragement of the Cultivation and Preparation of Flax, under the plans and patented processes of George Albermarle Cator, Esq., March 1859. MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

March 22, 1859.

MR. FAIRBAIRN ON GUNPOWDER.

Dr. Joule having taken the chair, a paper was read by the President, W. Fairbairn, F.R.S., &c., entitled "An experimental inquiry into the effect of severe pressure upon the properties of Gunpowder." During the late war, the Author received from the Government authorities at Woolwich different samples of Waltham Abbey gunpowder, for the purpose of submitting them to severe compression, in order to ascertain the effect of close contact between the particles upon its explosive properties. At the Government works there is no machinery of sufficient strength to give a pressure of more than 5,000lbs. to 6,000lbs. per square inch, and as it was considered advisable to test the quality of the powder under the influence of greatly increased pressure, the Author was requested to compress it in an apparatus of his own, calculated to effect its condensation under a force of more than 60,000lbs. per square inch. By carrying the pressure in this way far beyond the ordinary limits, it was expected that the precise influence of compression on the properties of the powder would be more clearly and accurately exhibited.

The samples of powder were placed in a wrought iron box, and compressed by a lever acting upon them by a solid piston with a force varying from 38,000lbs. to 67,000lbs. per square inch in the different specimens. When taken from the apparatus, the powder was found to have been consolidated into cylinders of 1¼ inches in diameter with smooth polished surfaces, every trace of its granular character having disappeared.

From the Report of Mr. Abel, the Chemist of the War Department, we learn that the specific gravity of the specimens was increased by the pressure, but not to so great an extent as might have been expected.

The specimens having been granulated were then burned, and it was found, on comparing the results with those of similar experiments on ordinary press-cake, that the amount of residue left by the compressed powders, after ignition, was greater in proportion as the pressure was increased. This increase of residue is probably to be attributed to the more gradual combustion and the diminished intensity of heat generated by compressed powder.

Experiments were then instituted to determine the amount of charcoal left unconsumed in the residue. They showed conclusively that the condensation of the powder had caused a more perfect chemical action in combustion, as the per-centage of carbon was considerably diminished in the compressed powders. Nitric acid was very carefully searched for in the residues of the compressed powders, but none could be detected, although in ordinary gunpowder a portion of the acid of the saltpetre always escapes decomposition.

An important objection to the application of increased pressure in the manufacture of gunpowder, notwithstanding the more intimate mechanical mixture of its constituents, is that the quantity of the residue left after combustion is increased, and a larger proportion of powder escapes ignition altogether when a charge is fired from a gun. If, however, larger quantities were submitted to compression, it is probable that the closer contact of the particles might be found to act beneficially, and a powder be produced of an improved and stronger quality, resulting from a judicious application of increased pressure and a more perfect system of granulation.

Dr. Roscoe expressed his opinion that we as yet know very little about the chemistry of gunpowder, and drew the attention of the Society to the interesting and important "Memoirs on the Analysis of the Products and Cumbustion of Gunpowder," lately published by Professor Bunsen. He found that the decomposition which occurs in an explosion, is by no means as simple as was formerly supposed. Besides the usual products of carbonic acid, carbonic oxide, nitrogen, and sulphide of potassium, Bunsen showed the presence of hydrogen, oxides of nitrogen, cyanide of potassium, sulpho-cyanide of potassium, sulphate and carbonate of potash, and various other salts, the relative quantities of which were all determined.

Several of the members suggested that the experiments, which were highly important, should be repeated, Government granting the funds which were requisite to prepare the compressed gunpowder in the same state of granulation and as it is in the samples with which it is to be compared.

The Sale of Gas.—Lord Redesdale has just introduced a Bill to regulate the measures used in the sale of gas. To prevent disputes and litigation it enacts that all contracts for sales of gas made and to be made by meters registering within two per cent. variation from the cubic foot containing 62 32 lb. avoirdupois weight of distilled water or rain water, weighed in air at the temperature of 62 deg. of Fahrenheit's scale, the barometer being at 30 inches, and by any meters registering within two per cent. variation from multiples or decimal parts of such cubic foot, shall be valid in law. Models of measures are to be made and verified under the direction of the Treasury. Power is given to justices and inspectors to enter houses and inspect gas measures and meters. The progress of the bill will probably be stopped by the proximate prorogation of the present condemned Parliament.

Mr. W. Lander, of Bristol, engraver, has patented the following improvements in engraving and printing for the purpose of ornamenting earthenware. According to his invention, he first engraves his subject in the usual manner on the surface of a copper plate. From this original plate he produces as many metal copies by the galvanic or electrotype process as there are colours to be printed. He then erases a part of the work previously engraved on the several plates, so that the portion of the engraving present on each plate shall be absent from the surface of all the rest. This done, the several portions remaining are then finished with the graver or otherwise, the work on each plate being completed sufficiently for printing. When the plates are required to be printed, each will be restricted to one particular colour, and when the successive impressions are made by the several plates on one sheet of paper, or other suitable material, the subject will then be completed for transferring to the ware. To ensure a true register in combining the parts of the subject on the several plates, he employs a metal frame for securing the plates and paper from the possibility of shifting from their proper positions during the printing of the rolling press.

The St. Germans viaduct of the Cornwall Railway is completed. The Government Inspector will commence his survey next week.

SOCIETY OF ARTS.

ON THE PRACTICAL BEARING OF THE THEORY OF ELECTRICITY IN SUBMARINE TELEGRAPHY, THE ELECTRICAL DIFFICULTIES IN LONG CIRCUITS, AND THE CONDITIONS REQUISITE IN A CABLE TO INSURE RAPID AND CERTAIN COMMUNICATION.

By S. Alfred Varley, Assoc. Inst. C.E.

[The paper read by Mr. S. Alfred Varley at this Society on the 30th ult., of which a brief abstract was given in our last number, deserves to be reported in these columns at greater length, because it was an attempt to withdraw electric telegraph engineers and others from "a laborious perseverance in almost empyrical experiments," and to induce them to seek guiding principles, to which canstant reference may be made while practical operations are pursued. The following is the paper (from which the introduction only is omitted) in the author's own words.]

The generally recognised theory of electricity, as I understand it, supposes all bodies in their normal condition to have two powers or forces resident in them directly opposite in their character, being exactly balanced; in bodies in their natural state these forces are completely neutralised and rendered inactive, producing the ordinary condition of matter.

To these powers the name of electricities has been given, and although we are still as ignorant at the present day as the ancients themselves with regard to what electricity actually is, yet the fact of the existence of the electric telegraph is a proof of the progress which has been made in a knowledge of the laws, at least, which govern electric phenomena.

In the year 1838, Dr. Faraday clearly developed the principles of induction and conduction, since which time no further progress has been made in the fundamental truths of the science, though much has been done to confirm their correctness and to develop their consequences.

In the Philosophical Transactions for 1838, will be found Dr. Faraday's views on the subject of induction and conduction; and these, to my mind, so clearly explain all electric phenomena, that it will be as well at once to refer to them before proceeding further. After giving reasons for his belief in the identity of induction and conduction, he says, "All these considerations impress my mind strongly with the conviction that insulation and ordinary conduction cannot be properly separated when we are examining into their nature, that is, into the general law or laws under which their phenomena are produced. They appear to me to consist in an action of contiguous particles dependent on the forces developed in electrical excitement; these forces bring the particles into a state of tension or polarity, which constitutes both induction and insulation, and, being in this state, the continuous particles have a power or capability of communicating their forces one to the other, by which they are lowered, and discharge occurs. Every body appears to discharge, but the possession of this capability in a greater or smaller degree in different bodies, makes them better or worse conductors, worse or better insulators, and both induction and conduction appear to be the same in their principle and action, except that in the latter an effect common to both is raised to the highest degree; whereas in the former it occurs in the best cases in only an almost insensible quantity."

In part the 2nd of the Philosophical Transactions of the same date will be found a summary of Dr. Faraday's views, which I will also quote:—

"1st. The theory assumes that all the particles, whether of insulating or conducting matter, are, as wholes, conductors.

"2nd. That, not being polar in their normal state, they can become so by the influence of neighbouring charged particles, the polar state being developed at the instant, exactly as in an insulated conducting mass consisting of many particles.

"3rd. That the particles when polarised are in a forced state, and tend to return to their normal or natural condition.

"4th. That being, as wholes, conductors they can readily be charged either bodily or polarly.

"5th. That particles which, being contiguous, are in the line of inductive action, can communicate or transfer their polar forces one to another more or less readily.

"6th. That those doing so less readily require the polar forces to be raised to a higher degree before this transference or communication takes place.

"7th. That the ready communication of forces between contiguous particles constitutes conduction, and the difficult communication insulation; conductors and insulators being bodies whose particles naturally possess the property of communicating their forces easily, or with difficulty, and bodies having these differences as they have differences of any other natural property.

"8th. That ordinary induction is the effect resulting from the action of matter charged with excited or free electricity upon insulating matter, tending to produce in it an equal amount of the contrary state.

"9th. That it can do this only by polarising the particles contiguous to it, which perform the same office to the next, and these again to those beyond; and that thus the action is propagated from the excited body to the next conducting mass, and these render the contrary force evident in consequence of the effect of communication which supervenes in the conducting mass upon the polarisation of the particles of that body.

"10th. That, therefore, induction can only take place through insulators; that induction is insulation, it being the necessary state of the particles, and the mode in which the influence of electrical forces is transferred or transmitted across such insulating media."

To determine for myself the law which induction obeys, in conjunction with my brother, Mr. C. John Varley, I have tried some experiments.

The principle upon which these were based was that of the dual character of electricity, and the fact established by Dr. Faraday, that all statical charge is sustained solely and entirely by induction.

In bodies in their normal condition, the opposite forces or electricities being balanced and united, no attraction for neighbouring particles exists, but when these forces are separated, as in the case of a Leyden jar, the attraction which a given quantity of electricity exerts for the similar amount of negative on the opposite coating, will be less in proportion to some law as the thickness of the intervening dielectric is increased.

It was, therefore, assumed that the amount of free attraction under these circumstances, or more correctly the amount of induction which would be thrown upon neighbouring bodies, would increase inversely as the attraction between the opposite coatings diminished.

The apparatus made use of was constituted in the following way:—A glass pillar, varnished, for better insulation, was mounted upon a board. On the top of this a brass plate was attached, and upon this plate the dielectric to be examined was laid. Over the dielectric another brass plate was then placed. A Leyden arrangement was thus constructed, the upper and lower brass plates representing the inner and outer coatings of an ordinary Leyden jar. A brass ball, suspended from a balance which had an adjusting arrangement, so that it could be raised or lowered, hung over the upper metal plate at a short distance from it.

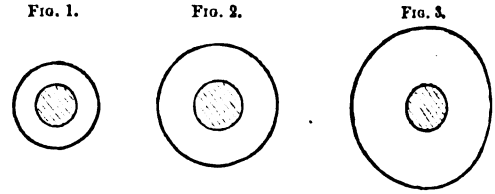
The *modus operandi* was as follows:—The upper brass plate was connected to the earth, and a series of sparks, through the medium of a sliding rod kept at a fixed distance from the prime conductors of a frictional machine, thrown into the lower brass plate of the Leyden arrangements, or the prime conductor was kept fully charged, and a carrier ball attached to a long glass rod was made use of to measure out definite quantities of electricity.

The room in which the experiments were performed was heated with a stove, and the dryness of the atmosphere indicated by a hygrometer, so that the insulation might be as perfect as possible. When a certain number of sparks had been thrown into the lower brass plate, the upper brass plate was disconnected from the earth, and the lower one attached to the balance, and if the tension of the charge was sufficient, the brass ball suspended from the balance was attracted down, and discharge ensued. The experiment was repeated again and again, and the number of sparks requisite to just attract the ball down, noted. Glass plates were the dielectric employed, and the experiment was tried first with one plate, then with two, and then with three plates of glass between the upper and lower brass plates, the brass ball suspended from the balance being kept always at a certain fixed distance from the upper brass plate.

The results obtained from a numerous series of experiments were that when two plates of glass were placed between the brass plates, only half the number of sparks which were required to raise the tension of charge sufficiently to cause discharge when one plate of glass separated the brass plates was requisite, and when three plates of glass divided the upper and lower brass plates, then a third of the number of sparks raised the charge to the same degree of tension, showing that through flat plates of glass, induction decreases in the inverse proportion to the thickness of the dielectric, that is to say, if the induction through one be 12, through 2 it will be 6, through 3—4, and so on.

In the case of a gutta percha covered wire, it was anticipated that as when the thickness of the gutta percha is increased, the outer surface increases at the same time, the decrease of induction consequent on the increased thickness of the insulating material would not be inversely proportionate to the depths of the gutta percha, but would follow some other law. To put this to the test, a series of Leyden arrangements were constructed in the following way:—three pieces of tube, of half an inch internal diameter, and 2 feet 6 inches long, were placed in the centre of tubes of 2 feet long, the internal diameters of which were 1 inch, 1½ inches, and 2 inches, and the space between the inner and outer tubes filled with melted resin. (Figs. 1, 2, 3.)

Fig. 1. Fig. 2. Fig. 3.



By this means three Leyden arrangements, with a uniform internal surface, but whose insulating material varied in thickness in the proportion of 1, 2, and 3, were constructed, and the same process as that already described with the flat plates was repeated. The results obtained are shown in the annexed table:

Diameter of Inner Tube	Thickness of Insulation.	Diameter of Outer Tube.	Inductive Force.
10	5	20	22
10	10	30	15·5
10	15	40	11·5

These results were very constant, but as resin was the only dielectric employed, the experiment requires repeating with other dielectrics, for there is reason to believe that with glass at least the decrease in induction consequent on an increased thickness of the dielectric would be somewhat greater than that indicated in the above table.

The reasons for this belief are the following:—When a galvanic battery is connected with the inner and outer coatings of a Leyden arrangement, induction will take place through the dielectric, and if the surfaces of the two coatings are equal, then the force will be equally divided over them; that is to say, if the battery force be 100, the tension of the charge on the one coating will be 50, and that on the other will be 50 also = 100. Let the surface of the outer coating be supposed to be infinite in extent, then the tension of the charge on the inner coating will approach infinitely near to 100, and the tension of the charge on the outer coating will be almost nil. An example of this we have when the earth represents one of the coatings of a Leyden arrangement; and this is the case in the prime conductor of a frictional machine, and also in the suspended wire of a telegraphic circuit; in these two examples the prime conductor of the machine and the wire of the telegraphic circuit represent the one coating, the air the dielectric, and the earth the other coating.

Now, consider a case where the outer surface is double that of the inner one, the tension of the charge on the inner coating will then be double that of the *outer*; an example of this we have in the above table, where the inner surface is 10, the thickness of the insulation 5, which may here be regarded as unity, and the outer surface 20—the battery force being 100. Divide this into three parts, and we get 33⅓. Give two parts for the tension of the charge on the inner coating, and one part for the tension of the charge on the outer coating, then we shall have for the tension of the inner surface, 66⅔; for the outer surface, 33⅓ = 100 when united.

Now, consider the third example in the above table. Inner surface 10, thickness of insulation 15, outer surface 40, or quadruple that of the inner surface. In this case the tension of charge on the inner surface will be four times that of the charge on the outer surface. In other words, the tension of the charge on the smaller surface will be 80, and that of the outer surface 20, the united tensions equalling 100; but the thickness of the insulation is 15, or three times that of the first example; and it has been shown that induction decreases in the inverse proportion to the thickness of the insulating material; we shall, therefore, have to divide by 3, and this will give 26·6 for the tension of the chargo on the inner surface.

In the first example it has been shown that if the force be 100, the

Digitized by Google

tension of the charge on the inner surface will be 66¾, which, to avoid fractions, we may regard as 67. In the actual experiment the inductive force measured was 22; 67, therefore, represents 22, and as 67 is to 22 so should 26·6 be to the amount of force which would be expected to be obtained in the last example; this, when calculated by a simple Rule of Three sum, gives 8·8 for the amount of inductive force. In the actual experiment the force obtained was 11·5, a result, therefore, sufficiently near to warrant further investigation, to ascertain whether the law which would seem to be indicated is correct, and whether it holds good with any other dielectric, such as glass, in which case the cause of the discrepancy, when resin is the dielectric employed, should be sought after.

I now proceed to conduction.

The law which governs the conduction of electrity has been very accurately ascertained, and would seem to follow the same law as induction, that is to say, if the sectional area be uniform throughout, the resistance which a conductor will oppose to the passage of a current will be directly relative to its length; or, the length of the conductor being determined, the resistance will be relative to its sectional area. In other words, a wire one mile long will oppose half the resistance of that which will be opposed by a similar wire two miles long, two wires, each two miles long placed side by side, which is the same thing as one of twice the sectional area, will oppose exactly the same resistance as a single wire one mile long.

The next thing to be considered is the part which the quantity and intensity of electric currents play in electric phenomena. The amount of force developed by an electric current, whether it be the deflection of a needle, the attraction of an armature in an electro-magnet, or the decomposition of water, is always relative to the dynamic quantity flowing. This fact has been well established, and the difference between quantity and intensity accurately defined; yet still, in practice, there is a want of a clear comprehension of the relationship of those terms.

Let a battery—say of ten pairs of elements, with ten inches of surface in each cell—be joined through a circuit perfectly insulated, and opposing very great resistance to the passage of the current; and the amount of force, or in other words, the dynamic quantity of electricity flowing, be weighed off by a magnetometer, and noted down. If now this battery be disconnected, and another of the same number of elements, but with twice the surface, be connected in its place, practically no more will be found to be flowing through the circuit than in the former case, the resistance which the wire opposes measuring out the quantity passing somewhat in the same way as the height of the column, and not the quantity of water, in a cistern, regulates the rate at which it flows from an orifice inserted in it.

Let the series be increased, and more will be urged through; and, if the number of cells be sufficiently numerous for practical purposes, the same dynamic quantity as a single cell would generate through a circuit of no resistance, will be found to be flowing.

In theory this point can only be approached, for the resistance of the wire can never be completely overcome. In theory, also, when the number of elements is not increased, the larger the surface the greater will be the dynamic quantity flowing, for the tension of the current is lowered in proportion to the amount of electricity flowing out of the battery; and, when drawing from a larger reservoir, which batteries of greater surface may be compared to, this same amount will not lower so much the general tension; consequently, there will be more intensity to urge the current through. But to return to practice. If the number of cells has been sufficiently extended so as to generate the same dynamic quantity as a single cell does through a circuit of nominally no resistance, a further addition to the series will not be attended with any beneficial effect, for there is already power enough to urge through all the electricity the battery is capable of generating; and the force developed is directly relative to the dynamic quantity flowing. Tension is only the medium by means of which this dynamic quantity is forced through the circuit.

It will be as well, perhaps, to define more precisely what is wished to be understood by the term resistance. When it is said that one circuit opposes twice the resistance of another, it is meant that the same tension of current will force half the dynamic quantity only through this circuit that it would through one opposing half the resistance; it follows that a given length of wire opposes the same resistance to half the dynamic quantity of electricity that half this length of wire does to double the dynamic quantity, and hence all circuits oppose to an infinitely small quantity of electricity an infinitely small amount of resistance.

The way in which quantity and intensity affect practical telegraphing has next to be considered, and whether there be any advantage in employing comparatively large over smaller dynamic quantities of electricity. It may be generally stated that when the insulation is very perfect there is no great difficulty in working with minimum quantities; but when the insulation is imperfect, larger dynamic quantities hold out a better prospect of working through. When a current is flowing through a circuit which offers, practically speaking, no resistance, let the cells of the battery be ever so numerous, it will possess no intensity worth noticing, for, as there is no resistance opposed to the force resident in the battery, the intensity is not brought into play. It is something like a powerful engine raising a light weight, the force is latent, but not brought into action. Let the battery, however, be connected through a circuit opposing considerable resistance; its intensity will then be developed.

Let the diagram (Fig. 4) represent a circuit which fulfils these conditions, one end of the wire dipping into the earth in the usual way, and the other connected with the copper pole of a battery composed of a numerous series of elements possessing very little surface and, consequently, capable of generating only a small dynamic quantity of electricity, and let the circuit be completed by connecting the zinc pole to the earth. The current will flow from the copper pole through the wire, thence to the earth, and back to the battery; and its working intensity will be dependent on the resistance which the circuit opposes, and can be measured in the following manner:—

Let another battery, but with a much smaller number of elements, be connected side by side with the larger battery to this wire, the zinc pole being connected to the earth and the copper to the wire, and introduce galvanometers in the circuit, between the large battery and the wire and between the small battery and the wire, so as to indicate the direction in which the currents are flowing. Both batteries will desire to send a current through the circuit in the same way, but should the small battery oppose much less resistance to the passage of a current through itself than is opposed by the long wire, then the greater quantity of electricity generated by the large battery will pass that way in preference to through the wire, and paralyze the action of the smaller battery; but if cell after cell be added to this little battery, when its intensity becomes greater than the resistance of the wire, a current will flow from it also in the same direction as that from the large battery through the wire, and the number of cells requisite just to do this will be an exact measure of the working intensity of the current.

Let the case now be considered where the insulation is not perfect; if there be sufficient leakage to let the small dynamic quantity, which the battery can only generate, escape on the road, no appreciable amount will reach the further end, the tension of the current will be lowered, and a less number of cells in the little battery will now be found to balance it. Adding to the number of these small pairs of elements will not give any appreciable assistance, but let the surface in each of the cells of the larger battery be increased so that a greater quantity may be generated than can escape through the leaks, represented in the diagram by the dotted lines, an appreciable amount will then reach the further extremity, and the telegraph instrument be rendered active. In such a case as this, adding quantity will raise the working intensity of the current, whilst increasing the intensity of the battery alone will scarcely affect it.

In some experiments tried by my brother, Mr. Cromwell Varley, and myself, on long leaky circuits, increasing the surface of the batteries alone, without adding to the series, raised the deflection on the galvanometer from 22° to 53°; and the last intelligible words uttered by the Atlantic cable, "Daniells are now in circuit," is a further testimony of the correctness of what has just been advanced.

The correctness of considering the inductive phenomena which manifest themselves in subterranean and submarine circuits, as a new fact suddenly brought to light, has been called in question in the early portion of this paper; a few words on its history will therefore not be out of place, before considering the way in which it affects telegraphing.

In 1838, Dr. Faraday pointed out the conditions which would cause the retardation of an electric impulse in its passage through a conductor. In 1848, the electric telegraph was in actual operation. The method adopted at that time for the insulation of the wires passing through towns, was to enclose a number of cotton-covered wires in a leaden tube, and then fill the tube with a mixture of resin and Stockholm tar. Reasoning on Dr. Faraday's observations, my brother, Cromwell Varley, was led to think that such circuits possessed conditions favourable for induction to manifest itself; he therefore searched for it, and succeeded in obtaining indications of induction. In 1849, gutta percha had been introduced, and as the insulation in gutta percha covered wires was much more perfect than in the cotton-covered ones enclosed in leaden pipes, induction manifested itself much more strikingly, and my brother made use of from that time as a more searching test of the perfection of the insulation than the deflection of a galvanometer, the capability of the wire to retain for a certain period the induced charge, and he stood alone for some time in making use of this test, others not having faith in it at that period, and in the same year he obtained indications of induction in an overground circuit. In the latter end of the year 1851, my brother was enabled to experiment upon a length of ten miles of gutta percha covered wire. At these experiments I assisted, and the conclusion he arrived at was, that if gutta percha covered wires were employed for circuits of any length, as was at that time proposed, induction would manifest itself so powerfully as to offer serious obstacles to telegraphing with the apparatus then in use, the truth of which prediction was subsequently verified. In Prussia, however, as early as 1850, Mr. W. Siemens had employed gutta percha covered wires for circuits of considerable lengths, and encountered the inductive phenomena, an account and explanation of which he published during that year. This fact was not known on this side of the channel until after gutta percha covered wires throughout the whole lengths of the circuit were also employed in this country, and that was in the year 1854.

To Dr. Faraday, however, is due the whole credit in this matter, and I have only alluded to its telegraphic history, as I cannot help feeling it as a sort of reproach to practical electricians that it should go forth that induction, which was manifesting itself step by step before their eyes, came suddenly and unexpectedly upon them. The following extract from Dr. Faraday's researches of 1838 is so instructive, and teaches such a valuable lesson, that I cannot refrain from quoting it. Alluding to Professor Wheatstone's well-known experiment, he says:—

"If the two ends of the wire were immediately connected with two large insulated metallic surfaces exposed to the air, so that the primary act of induction, after making contact for discharge, might be in part removed from the internal portion of the wire at the first instant, and disposed for the moment on its surface, jointly with the air and surrounding conductors; then, I venture to anticipate, the middle spark would be more retarded than before, and if these two plates were the inner and outer coatings of a large jar, or Leyden battery, then the retardations of that spark would be still greater."

(To be continued.)

Literature.

A Manual of Applied Mechanics. By WM. JAS. MACQUORN RANKINE, LL.D., C.E., F.R.S.S., L. and E., President of the Institution of Engineers in Scotland, and Regius Professor of Civil Engineering and Mechanics to the University of Glasgow. London and Glasgow: Richard Griffin and Co., Publishers to the University of Glasgow. 1858.

[THIRD NOTICE.*]

WE now proceed to justify the opinion we have ventured to offer of this work by reference to the particular treatment of some of the subjects contained in it. And first of all the most glaring instance of the unfitness of this work to be placed in the hands of a learner as a text-book, or into the hands of a practical engineer as a *vade-mecum*, is to be found in the author's laying down the theory of couples as the basis of the mathematical portion of his work. This arrangement has the single merit of novelty or originality, while it has the disadvantage of attempting to familiarize the tyro at the outset of his career with conceptions which, even after considerable experience of the modes of combining single forces, he has usually great difficulty in forming.

When a student has once obtained an adequate idea of a force, and of the mode of estimating its effects as regards magnitude, direction, &c., it has, of late years at all events, been the approved course among writers to proceed to the discussion of the effects of a combination of single forces applied to a body at one point. The proposition well known as that of the parallelogram of forces has thus been usually laid down as the basis of mechanical inquiry. The fundamental propositions of the theory of couples have on this system been brought before the learner as a natural and necessary consequence of the laws of combination of single forces. In this way the learner has been led to discover, as it were, for himself that a couple can produce no motion of translation, but only one of rotation; and the conception of the effects of couples has thus been made easy and distinct to his mind. On Professor Rankine's method his faith is at once subjected to a rude trial, and his power of conception most severely taxed. Thus (page 21, article 27) he is expected at once to admit as a fundamental truth that "the tendency of a couple is to turn the body to which it is applied in the plane of the couple—that is, the plane which contains the lines of action of the two forces." We defy a learner to form any distinct conception of the tendency here laid down. About *what point* is the tendency of a couple to produce motion? In the ordinary mode of treating this subject the student can discover this from the very fundamental proposition which introduces him to his first notion of a couple. Our author leaves this point indefinite, nor does he by any subsequent definition supply this desideratum.

Again, our author draws very severely on the faith and powers of conception of his readers when he states, as an axiom, that in order that two couples, similar in direction and of equal force and leverage, may be exactly alike or *equivalent* in their tendency to turn the body, "it is necessary and sufficient that their planes should be either identical or parallel." As a necessary consequence of this imperfect treatment in establishing the lemma that "*two couples of equal force acting in the same direction with the same axis are equivalent to* a couple whose moment is the sum of their moments," the author is obliged to assume that the arm of couples may be turned anyhow in the plane in which they are applied.

Nothing, again, can be to our mind so unsatisfactory as the author's proof of the theorem that, "*if the moments of two couples acting in the same direction and with the same axis are equal, those couples are equivalent.*" This is made to depend on an algebraical juggle—no doubt very ingenious and clever—rather than on a sound mechanical investigation. In fact, throughout this elementary portion of his work, the learned Professor has entirely lost sight of one great object which an elementary writer ought always to have in view, viz., making each successive proposition a means of familiarizing his readers with the elementary conceptions of his subject, and adding something to their breadth.

We have again to quarrel with our author for departing from the received nomenclature and definition in treating this part of his subject. Those of our readers who are familiar with the mathematical investigations of mechanics are well aware that the axis of a couple is generally defined to be a straight line perpendicular to the plane of a couple, and proportional to its moment in magnitude. This definition of "an axis" has many advantages in simplifying the statement of propositions. Professor Rankine's definition is simply—"The axis of a couple is any line perpendicular to its plane." We shall not pursue the author further into his theory of couples; to the absurdity of the mode of treatment we have pointed out, the cope-stone is placed by demonstrating the parallelogram of forces by the theory of couples. We are, therefore, obliged to arrive at the conclusion that the author's mode of "setting forth those first principles which are common to all branches of mechanics," is for all purposes of instruction a failure.

In his fourth chapter the Professor makes a great parade of a principle which he dignifies by the name of "Parallel Projections in Statics." It is simply this: that "if two figures are so related that for each point in one there is a corresponding point in the other, and to each pair of equal and parallel lines in the one there corresponds a pair of equal and parallel lines in the other, those figures are said to be parallel projections;" and hence the author infers that if when forces, &c, have been geometrically represented, certain propositions have been established with regard to them; the truth of these or similar propositions may be deduced with regard to other forces, &c., whose geometrical representations are parallel projections of the former. To this we can offer no objection; but it does not seem to us so great a matter after all, as to deserve to be made the foundation of many new principles, *e. g.*: "Principle of Transformation of Frames," "Transformation of Structures in Masonry," &c., the practical application of which, moreover, the author leaves very much to the reader's own ingenuity.

A very prominent feature of the work before us is the complete treatment of the theory of "Stress." In a purely theoretical work this would find a fitting place, and the mathematical reader could not peruse it without deriving much profit; but we think our readers will be much astonished to learn that the fundamental principles of fluids, viz., that in a fluid at rest the pressure at any point varies directly as the depth below the free surface, and that fluids press equally in all directions, are deduced from three differential equations derived from the theory of stresses; and no other explanation or illustration of these most important principles are vouchsafed. Thus, facts of which a tyro may obtain a very adequate idea without the slightest knowledge of the principles of the Differential Calculus, are made by Professor Rankine to rest entirely on the higher mathematics. How could our author have more painfully or ludicrously have contravened his own position with respect to practical scientific instruction, viz., "that so far as possible mathematical intricacy ought to be avoided," and that "in treating of the practical application of scientific principles, an algebraical formula should only be employed when its shortness and *simplicity* are such as to render it a clearer expression of a proposition or rule than common language would be, and when there is no difficulty in keeping the thing represented by such symbol constantly before his mind."

This fluid-investigation (in a treatise, be it remembered, called a "Manual of Applied Mechanics") is so rich, that we cannot forbear inserting it. At page 100, art. 110, theorem 11, the author lays it down that "In a perfect fluid the pressure at a given point is normal and of equal intensity in all directions," of which the following is the proof:—

"*Fluid* is a term opposed to *solid*, and comprehending the liquid and gaseous conditions of bodies, which have been defined in article 4. The property common to the liquid and gaseous conditions is that of *not tending to preserve a definite shape*, and the possession of this property by a body in perfection throughout all its parts, constitutes that body a *perfect fluid*. The parts of a body resisting alteration of shape must exert tangential stress; a perfect fluid does not resist alteration of shape, therefore the parts of a perfect fluid cannot exert tangential stress; therefore the stress exerted amongst and by them at every point and in every direction is normal; therefore, at a given point, it is of equal intensity in every direction. Q. E. D."

Pretty well this for a learner!

Again, at p. 116, for equilibrium of fluids, the following is given:—

"In adapting equations (2) of art. 116 [too long to be inserted here], to this case, it is convenient to take x to denote vertical co-ordinates, and to make it *positive downwards*. Then bearing in mind that p is now a thrust, being positive (and not a pull when positive and a thrust when negative, as in the general problem), we obtain the following equations:—

$$\left.\begin{aligned} \frac{dp}{dx} &= w \\ \frac{dp}{dy} = 0, \quad \frac{dp}{dr} &= 0 \end{aligned}\right\} \quad \ldots\ldots (2).$$

The first of these equations expresses the fact that in a balanced fluid, *the pressure increases with the vertical depth at a rate expressed by the weight of the fluid per unit of volume;* and the second and third express the fact that *in a balance fluid, the pressure has no variation in any horizontal direction:* in other words *that the pressure is equal at all points in the same level surface.*"

We think we have said enough to establish our position that Professor Rankine's work is not what it professes to be, "A Manual of Applied Mechanics," but much more what he himself states a work intended for "practical scientific instruction" ought not to be. We cannot commend it to the reader unless he be already an accomplished mathematician, thoroughly acquainted with the principles of mechanical science, not to be deterred by a crabbed and forbidding nomenclature, but anxious to pursue the principles into the highest *theoretical* development they have yet attained. To such a reader the work before us will present much that he will find useful and interesting. He must be a bold man, indeed, who will venture to recommend the treatise to the learner or the practical man whose mathematical knowledge is small, or who will dare to affirm that the author has done anything by its publication towards bridging the gulf which now unfortunately separates the theoretical from the practical.

Tents and Tent-life, from the Earliest Ages to the Present Time. To which is added the Practice of Encamping an Army in Ancient and Modern Times. By GODFREY RHODES, (late) Captain of Her Majesty's 94th Regiment. Illustrated by several engravings. London: Smith, Elder, and Co., Cornhill. 1858.

OUR late articles on the improved tents of Major Rhodes have brought us acquainted with this exceedingly entertaining volume. The length to which those articles extended renders it undesirable for us to occupy much further space on the subject now. We would wish, however, to have it understood that, although the volume was suggested in connection with the invention of the gallant author, it has by no means suffered on that account; on the contrary, it has evidently been prepared with faithful labour and research, and is a most valuable contribution to the literature of the time. It will be found, we repeat, an exceedingly entertaining volume and that by all classes of readers.

Chambers's Encyclopædia; a Dictionary of Universal Knowledge for the People. No. 1. W. and R. Chambers, London and Edinburgh. 1859.

WE hail the appearance of the first number of this work with unaffected pleasure. The type and paper are both excellent, and the quantity of

* The preparation of this article has been delayed by the illness of the writer.

Digitized by Google

matter for the 1½d. is abundant. This publication will be a great boon to large numbers of our countrymen, especially to the working classes, and we would urge such of them as we address to commence to obtain and study it as it is published week by week, or month by month. At the same time we entreat the publishers to secure soundness, at any cost, in their scientific articles. Are they quite sure that "aberration of light" is philosophically defined by the words, "an apparent alteration in the place of a star?"

Routledge's Illustrated Natural History. By the Rev. J. G. Wood, M.A., F.L.S., &c. Part I—April. London: Routledge, Warnes, and Routledge, Farringdon-street.

There is so much exquisite mechanism at work in the animal life of the creation, that no thoughtful student of mechanics and machinery should fail to enrich and stimulate his mind by the study of Natural History. We therefore receive with much satisfaction this first part of Messrs. Routledge's new work. The author is well known as a most exact and able writer on the subject, and the publishers have manifestly resolved to second his ability by type, paper, and illustrations of a very superior kind. They are likewise very liberal in the quantity of matter which they give. This first number contains considerably more than twice as much letter press as the monthly number of Mr. Thackeray's novel, the "Virginians," at the same price. It is very gratifying to find high-class science produced for less than one-half the cost of high-class fiction.

The Problem of Squaring the Circle Solved; or the true Circumference and Area of the Circle discovered. By James Smith. London: Longman, Brown, and Co. 1859.

On the first page of this tract we are distinctly told what we felt confident we should find on some page or other, viz., that the author "never went through a regular course of mathematics." This intelligent gentleman endeavours to effect his object by making circles and squares of cardboard, copper, &c., and weighing them, and so forth! What a pity it is he did not first take the pains to acquaint himself with the theories and the *facts* which he proposed to overthrow. We do not blame Mr. Smith for either writing or publishing his paper, but we cannot recommend it to our readers except as a matter of amusement.

How to Lower Ships' Boats. By C. Clifford. *Fifth Thousand.* London: Charles Wilson, 157 Leadenhall-street. 1858.

We recommend this pamphlet to persons who are, or ought to be, interested in the highly-important subject of saving life at sea. It well deserves study, and will repay perusal in many more respects than one.

The British Workman for January, February, March, and April, 1859. Partridge and Co.

The Band of Hope Review for January, February, March, and April, 1859. Partridge and Co.

We cheerfully devote a few lines to a notice of these unpretending but most useful publications, which circulate so largely among labourers, mechanics of inferior grades, and the families of these classes. The January number of the *British Workman* contains an excellent sketch of the life of George Stephenson, condensed from Mr. Smiles' work. The tone and tendency of these numbers are most praiseworthy throughout.

LIST OF NEW BOOKS.

New Dictionary of Quotations from Greek, Latin, &c., 7s. 6d.

Parent's Cabinet of Amusement and Instruction, new edit., Vol. V., 1s.

Photographic Fac-similes of Antique Gems of the late Prince Poniatowski, £10 10s.

Jean's (H. W.) Navigation and Naut. Astron., Part II., 4s.

Hatterseley's (J.) Potato Disease and its Remedy, 6d.

Wordsworth's (C.) New Joint-stock Company, Law of, 1856-7-8, 7th edit., 8vo., 4s., sewed.

Parliamentary Proceedings.

The Patents for Inventions (Munitions of War) Bill passed through committee, in the House of Lords, on Tuesday, the 5th instant.

On Wednesday April 6, in the House of Commons, Sir J. Pakington entered into explanations respecting the reports of various committees on naval and dockyard expenditure, naval machinery, and the expenses of shipbuilding (the last by the Surveyor of Navy), all of which were laid on the table of the House—excepting that on Dockyard Economy. He recommended a committee of the House on the subject when the new Parliament assembled.

Lord Clarence Paget explained that his wish was simply to return to the method of preparing the Navy Estimates which was in vogue prior to 1819.

A short and inconclusive discussion followed on tenders for naval machinery, on Admiralty anchors, and on Captain Kynaston's patent hooks for lowering boats.

Sir C. Wood and Sir J. Pakington then skirmished at great length, the subject in dispute being the state of the navy when Sir Charles retired from office.

A DEFENCE OF FARADAY.

Gentlemen,—You have republished (in No. 12, for March 18) from the *Athenæum* some of the critical remarks of its mathematical reviewer on Faraday's additional observations on the Conservation of Force, in which remarks, coupled with those of a former review, there is evinced a disposition to undervalue without sufficient cause the mind and the ideas of a most eminent philosopher, even when propounding his views on a subject which he is specially qualified to discuss, namely, the *philosophy* of force, as a theme distinct from its mathematics or quantitative relations. This depreciatory attack is unfair, because, touching the experimental and logical relations of force, it is *not* founded on deep views of the realities of things, as consisting of either facts or inferences, in which department of knowledge and inductive reasoning Faraday is as much at home, to say the least, and is as competent to discuss any questions therein, as any mathematician can ever hope to be. The reviewer is, no doubt, his master in regard to deductive reasoning from abstract ideas of quantity, and I believe I may add, that no one—not excepting even Sir William Hamilton—has penetrated so deeply into the intricacies of syllogism as himself; but as to that logic which is yet to be written and systematised—if indeed it be susceptible of system—that logic which gives point and device to the efforts of the experimentalist, and is alike characteristic of practical sagacity and of profound philosophy,—in that logic of induction, the reviewer, instead of being his critic, ought rather to stand before him in the humble attitude of one of his own college pupils, if haply indeed he could learn a little of what nature only fully imparts. This attack is unfair, again, because it rests on the shallow ground that Faraday does not talk with the shibboleth of *modern* mathematicians, but presents his views, independent of the particular physical and theoretical form, in which they are accustomed for scientifically convenient purposes to invest their conceptions of force, but prefers rather to speak of it in a general sense. As well may the advocates of the emissive and undulatory hypotheses of light join to deride the philosopher who should choose to investigate the phenomena (as Brewster has been accustomed to do) independent of both the technical language and theoretical ideas of either of their respective schemes.

Now, the doctrine of the conservation of force is an inductive principle, like that of gravitation, but still more general, and to which gravitation itself, in its *physics*, must be made amenable; and it results from a comprehensive survey of the phenomena of nature, but directed more to the complicated relations connected with the constitution of bodies, than to the more simple movements of the celestial bodies in space, which the reviewer is able more easily to grasp, instructed therein, as he is, by a century of labours of the most eminent mathematicians who ever lived. But Faraday's labours belong not to routine attainments; they evince profound and original research; and of all philosophers, none have so much reason to be impressed with a sense of this doctrine being a true induction from molecular phenomena as himself. And mathematicians who are not philosophers travel beyond their domain, and diminish the prestige which it is more fashionable than reasonable to attach to their vocation, by cavilling at the inductive and philosophical conclusions at which such a man arrives. Let them, at least, meet him on his own ground—not indeed of original research, for that would be asking a little too much—but of general inductive reasoning. And instead of taking the high and sheltering position of self-assumed superior but inapposite attainments, let them review the subject with a disposition to acquire both general knowledge and more comprehensive views of things, although by so doing they should be obliged to revise some hypothetical opinions concerning the physics of gravitation in which they have hitherto indolently acquiesced. New applications of ideas and suggested improvements proceed so generally from the outside of the professional circle, that it has almost been adopted as a popular aphorism. But how is it that this principle of the conservation of force seems to come upon some mathematicians with the surprise, as it were, of a new truth? It is, I believe, because that it is now perceived to be no barren speculative idea, but a fruitful inductive proposition, capable of many important applications both in physical and practical investigations; and so, because of this extension, mathematicians more conversant with force in its sensible and measureable manifestations, in matter in the mass, became coy in regard to it as respects molecular phenomena. But when it was contended, and not by one of themselves to whose authority they could defer, that supplemental to an oversight of their own, gravitation must also be made amenable to this principle,—that its law, although a true mathematical expression of its action, is not obedient thereto in respect to the physical aspect of gravitation as an ultimate phenomenon,—that as a consequence, either associated phenomena must be sought for, which, with itself, must be included in some higher generalisation, or else that some explanatory considerations based on the principle of radiation must be accepted—no wonder they should be startled as though by a novelty and a heresy, and be disposed to disparage both the philosopher and his philosophy.

Wherefore it is that the reviewer would fain substitute for the general philosophical principle of the conservation of force, the particular mathematical truth, or theorem, concerning the conservation of momentum. By confusing, or inveterately associating—it matters not on which horn the fallacy is impaled—the mathematical expression of the equality of action with the physical expression of integral existence, he would have us to understand that all that is sound in one kind of conservation is to be found in the other. But why may they not co-exist? He says that "two equal and opposite momenta count as nothing in the [his] principle of *conservation*, not only when they shock each other and produce *rest*, but before;" that, in fact, momentum is being conserved even whilst being destroyed! Here is both a solecism in language and a paralogism in argument, although what is meant is correct enough. It is anomalous to talk of the conservation of momentum—simply of momentum, instead of the equality of action—and it is even contradictory, when motion, its most prominent element, is admitted to be absolutely destroyed in the production of rest; and it is beside the mark, when the question in dispute is a physical one, to give a mathematical answer about what no one controverts. That "the sum total of all the forces in the universe is equal to—*nothing*," is, of course, true in a mathematical sense, touching the mathematician's sole theme, the action of force; but by using the word "nothing," he would appear to point to a philosophical sense in opposition to that conservation which he repudiates, of force both collectively and individually being *something*, ever existent, and constant in amount. And, indeed, he makes this statement in connection with "the law of conservation *of force* strictly so called." Does he dally and palter, then, between the physical and the mathematical sense? Undoubtedly equal and opposite forces are equal to *zero;* but it is only in our mathematician's world that such zero is equal to "nothing." In the world of realities, such zero is perfectly compatible with continued existence, accompanied with integrity of power, admitting neither of increase nor of diminution whilst manifesting itself in different forms; otherwise, our members of Parliament, for instance, would be in a poor plight, if when votes are equal and opposite, they personally are to be deemed equal to—"*nothing*." Nullification is not annihilation. Forces live to fight again another day, even though they should put each other *hors de combat*.

It is not the algebraical zero that is in question; that zero concerns action, and no one demurs to the mathematical account of the matter, which, indeed, is a corollary from the third law of motion. It is the arithmetical zero, or cipher, in the arithmetic of whole numbers, to which the principle of the conservation of *force*, in apposition to that of equality of action, stands related; *that* zero concerns existence and constancy of endowment or the integrity of the unit, and is absolute, meaning truly now—"*nothing*." Now, the reviewer, great as are his talents, must not, through the algebraical pre-occupancy of his mind, practice an imposition either upon himself or upon us, by confounding the nature of the two zeros, or whilst talking of the one, covertly mean the other. Force, as to its existence and integrity, neither proceeds from nor returns to the absolute zero. It is a unit, ever on the sole positive side of the arithmetical zero, but the action of forces may be in units on opposite sides of the algebraical zero. Conservation, then, of both kinds are compatible and co-exist; and it is conservation in the physical aspect which Faraday and the philosophers who agree with him uphold; and yet, without controverting the mathematical conservation of the equality of reciprocal action, and of the motion of the centre of gravity. And this physical conservation (in respect to gravitation when confined to its own form of force, and omitting the addendum of its constancy unaffected by distance) the reviewer will in reality no more deny than Faraday himself, seeing that it stands as the *sine quâ non* of that mathematical conservation of momentum, as he calls it, which, with something like a love for an idle paradox, he would substitute for it.

Gentlemen, you will think it right, I am sure, that future historians should have the means of knowing that even at the time of an unjust depreciation of his mind, talents, and ideas, there were not wanting defenders of the fair fame of Faraday. This vindication will be by no means complete without another letter, but I scarcely hope you can afford more space for a somewhat recondite subject. For the same reason alone, I wish it to be understood, I refrain from replying to the articles by "A Mechanic." I am, &c.,

BENJ. CHEVERTON.

[We feel in a certain sense bound to give place to the above letter, because it is the only defence of Professor Faraday's views of Conservation of Force which has been sent us, and for other reasons. Having undergone the misfortune (as Mr. Cheverton would probably deem it) of a mathematical training, we are perhaps incapable of forming a correct and adequate opinion upon this question. However that may be, we confess that we are quite incapable of replying, with any satisfaction to ourselves, to the above letter—for we do not understand it. We have a tolerably clear conception of Professor Faraday's views, and an equally clear apprehension of those points on which we believe him to be in error; but the views, or at any rate the letter, of his defender passes our understanding. We are most willing—nay, we are really anxious—that we shall keep back nothing which the illustrious Professor would himself deem serviceable either to him or to the truth; but in the absence of all knowledge on that point we really do not see of what avail another letter like the above can be. We say this with the utmost respect for the long experience which our correspondent is known to have had in matters of science.—Eds. M. M.]

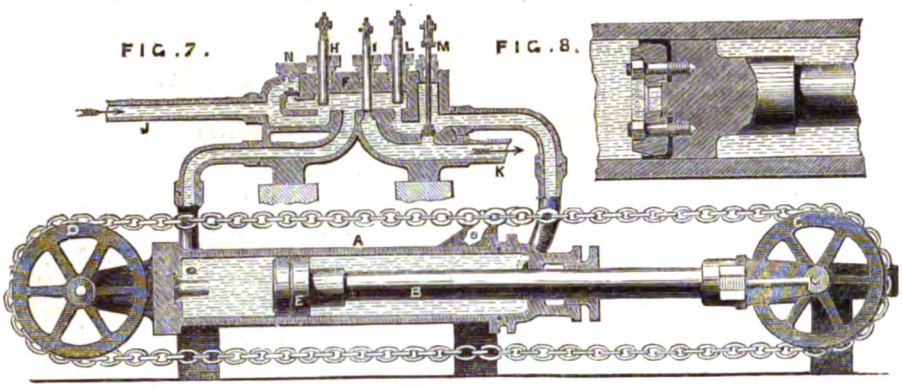

FIG. 8.

FIG. 9.

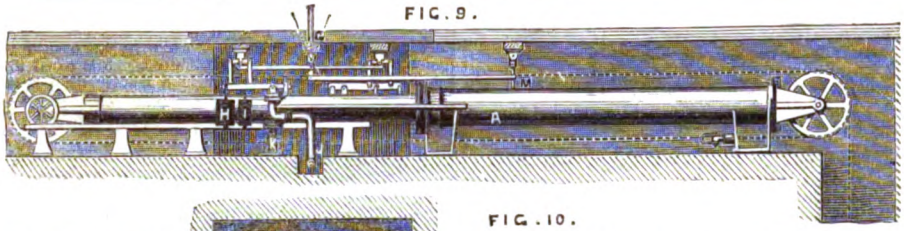

FIG. 10.

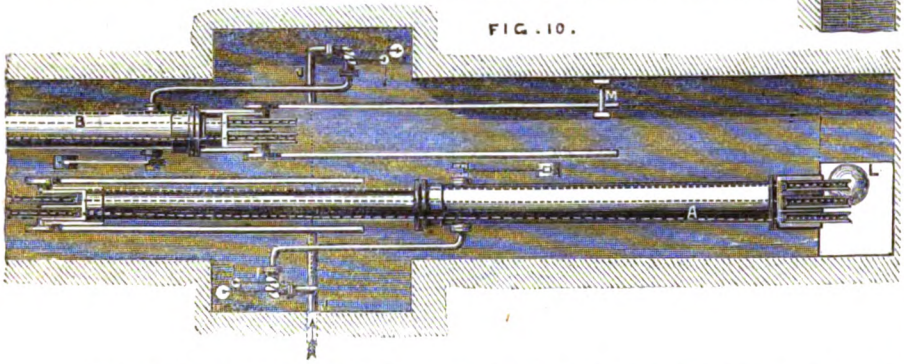

IMPROVED WATER-PRESSURE MACHINERY.

By Sir W. G. ARMSTRONG, C.E., F.R.S., Engineer to the War Department for Rifled Ordnance.

(*Continued from page* 220.)

To meet variation of load it was formerly the practice to combine three of the pressure cylinders so as to act either separately or collectively upon the lifting chain; but the writer has more recently introduced a method by which a variation of power is obtained with a single bored cylinder fitted with a combined piston and ram. Fig. 7 is a longitudinal section of the cylinder and valves of a double power hydraulic crane; and Fig. 8 is a section of the piston enlarged. *A* is the cylinder fitted with the piston *E* and ram *B*; the water from the accumulator enters the valve-chest *F*, through the pressure pipe *J*, and the inlet-valve *H*. For the lower power the water is admitted to both sides of the piston *E*, by opening the valve *L*, as shown in the drawing, in which case the power exerted and the water expended are each proportionate to the area of the ram *B*. For the higher power the valve *L* is closed and the valve *M* opened, so that the front side of the piston *E* is thrown open to the exhaust *K*, and the result both as regards power and expenditure, is then proportionate to the full area of the cylinder *A*. It is seldom necessary to have more than a double power; but where a lower or third power is required, a smaller ram may be inserted within the other, but in this case it is necessary to make fast the larger ram while the smaller one is at work. For lowering the load the valves *H* and *M* are closed and the outlet valve *I* opened, allowing the water to escape from the cylinder *A* into the exhaust pipe *K*; at the same time the valve *L* is also opened to allow the water to follow up the piston in the inward stroke.

In hydraulic cranes the power is applied not only for lifting the load, but also for swinging the jib, which latter object is effected by means of a rack or chain acting on the base of the moveable part of the crane, and connected either with a cylinder and piston, or with two single-acting cylinders applied to produce the same effect by alternate action. Figs. 4 and 5 (page 220), show the arrangement of the two cylinders *N* and *O*, for turning the crane, fitted with rams acting, by a chain passing round the base of the crane-post *F*. The motion is controlled by means of a slide-valve worked by a handle situated beside the handle *G*, so that while the water is admitted to one cylinder the other is open to the exhaust. The travel of the rams is limited by means of a tappet rod connected with the handle of the slide-valve, whereby the crane is prevented from being turned round too far.

The absence of any sensible elasticity in water renders the motions resulting from its pressure capable of the most perfect control by means of the valves which regulate the inlet and outlet passages; but this very property which gives so much certainty of action tends to cause shocks and strains to the machinery by suddenly resisting the momentum acquired by the moving parts. Taking for example the case of a hydraulic crane swinging round with a load suspended from the jib, the motion being produced by the water entering into one cylinder and escaping from the other, it is obvious that if the water passages be suddenly closed, the ram of the latter, impelled forwards by the momentum of the loaded jib, but met by an unyielding body of water deprived of outlet, would be brought to rest so abruptly as to cause, in all probability, a fracture of the machine. So also in lowering a heavy weight, if the escape passage be too suddenly closed, a similar risk of injury would arise from the sudden stoppage of the weight, if a remedy were not provided. But these liabilities are effectually removed, in the case of a single-acting cylinder, by employing a relief valve in connection with the water passages, consisting of a small clack valve, opening upwards against the effective pressure, so as to permit the pent-up water in the cylinder to be forced back into the pressure pipe whenever it becomes subject to a compressive force exceeding the pressure given by the accumulator. In the case of a double-acting cylinder, fitted with a piston and slide valve, or where two single-acting cylinders with rams working alternately are controlled by a slide-valve, as in the instance of the cylinders *N* and *O*, Fig. 5 (page 220), for turning the crane, relief valves are employed in connection with the slide valve, consisting of four small leather flap valves arranged as shown in Fig. 6 (page 220). The passages *PP* communicate with the pressure pipe *J*, and the passages *EE* with the exhaust *K*. When the slide valve is moved in the direction of the arrow, the pressure is first cut off from the port *R* by the lap of the valve, the port *S* being still open to the exhaust *K*; at the same instant the flap valve *T* opens upwards and allows a small quantity of water to pass from the exhaust *K* into the port *R* to follow up the ram until brought to rest. When the slide valve arrives at the centre position, as shown in the drawing, the port *S* is closed to the exhaust; and the pressure in the port *S* being increased by the further motion of the ram before it is completely stopped, the second flap valve *U* is raised and a small quantity of water forced back into the passage *P* communicating with the pressure pipe *J*. When the slide valve is moved in the opposite direction, the two remaining relief valves are called into action in the same manner. By these means all jerks and concussions are avoided, and perfect control over the machine is combined with great softness of action.

The method which the writer has most generally adopted for opening and closing lock gates by means of hydraulic pressure, consists in applying to each gate a pair of cylinders with rams and multiplying sheaves similar to those constituting the hoisting apparatus in hydraulic cranes. One of these cylinders opens the gate and the other closes it, the whole of the machinery being placed in chambers beneath the ground, as shown in Figs. 9 and 10. The water is admitted from the pressure pipe *J* to the cylinder *A*, through the inlet valve *H*, by means of the handle *G*; the same motion of the handle also opens the outlet valve of the other cylinder *B*. The opposite motion of the handle *G* opens the outlet valve *I*, allowing the water to escape from the cylinder *A* into the exhaust pipe *K*, and at the same time admits the pressure to the cylinder *B*. A stop *M*, connected with the handle *G*, prevents the ram from travelling too far in the out-stroke, by closing the inlet valve; and the return stroke of the ram is effected by means of the weight *L*. This arrangement is in use at the Sunderland Docks, the London Docks, the Victoria Docks, and the West India Docks, and is now being applied to the new 100 feet entrance to the Liverpool Docks

(To be concluded in our next.)

DIVIDING METALS BY ROTATION.

A communication has been made to the Society of Civil Engineers of Paris, relative to a new method of obtaining metals in a finely-divided state by means of rotation—in fact, in a manner similar to that which has been used for the production of small shot. In the present instance the machinery employed consists of a disc of fire-clay mounted on a vertical axis, and made to revolve at the rate of 2,000 turns a minute. The metal is allowed to fall in a state of fusion upon this disc, and is thrown off in the form of powder, which is cold before it reaches the ground or receptacle. The powder of lead thus obtained is proposed to be used in the production of masticot, or yellow oxide of lead; for this purpose the powder is damped, and then heated to a moderate degree, when the surface of each atom at once becomes covered with the protoxyde, which is removed by washing, and the process repeated. By the addition of acid, white lead may in like manner be produced. An experiment was made with the apparatus upon iron, but that metal retained its heat too long to permit the division to take place, during the time the molten metal remained in the air; it was suggested, however, that fine iron might be produced for special purposes by submitting it to the action of the machine, in order to disengage from it sulphur, phosphorus, and other foreign matters before moulding. The President of the Society objected that the rotating action of the foreign bodies contained in the iron could only be effected at the cost of the combustion of a portion of the iron itself, as occurred in casting, and also, as he stated, happened in the case of Mr. Bessemer's apparatus.

At the last meeting of the Mersey Dock board, Mr. Bold called attention to the subject of placing the time-ball at the Observatory in a better position. The expense of removing the ball to the top of Victoria tower was estimated at £100, and the erection of a new ball at the top of the Albert warehouses at £150. Mr. Mondel said the subject had not been lost sight of. Wires were, at present, being laid across the basins for carrying on the communication from end to end of the docks. It is not intended to carry the wires across the west side of the entrances at present, except with a view of communicating with the necessary offices. The submarine cable, for a telegraph to Holyhead, is to be supplied by Messrs. Glass, Elliott, and Co., the well-known makers.

JOBSON'S APPARATUS FOR CRUSHING AND SIFTING.

Mr. Robert Jobson, ironfounder, of Wordsley, Stafford, has invented an apparatus for crushing and sifting, in which a hopper and crushing rollers are fixed within a rotating sieve in such manner that the crushed matters coming from the crushing rollers descend on to the part of the sieve which is below them; and in order that any matters which may have passed through between the crushing rollers, and yet not be sufficiently crushed to pass through the sieves, may be again raised into the hopper, there is a shelf or shelves fixed longitudinally to the interior of the sieve, by which such matters are raised up into a position to fall into the hopper, and thence pass again through between the crushing rollers. When desired, the crushing rollers are so arranged that they can be heated.

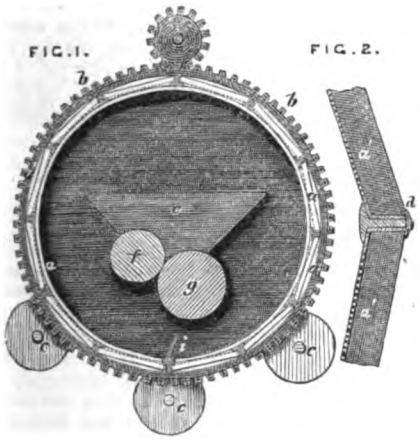

Fig. 1 is a transverse section of the machine, and Fig 2 shows the manner in which the sieves are fixed and retained in the spaces between the longitudinal bars of the cylinder. The cylindrical frame *a*, *a*, is composed of two rings, made by preference with flanches; these rings are connected together by longitudinal bars of T iron, and at one or both ends of the framed cylinder is fixed a toothed ring *b*, by which, when the framed cylinder *a*, *a* is supported by rollers *c*, *c*, *c*, at each end, motion is communicated to the cylinder *a*, *a* by a pinion or pinions, on an axis driven by any suitable power. The rings of the framed cylinder rest on the rollers *c*, *c*, *c*, and the flanches on such rings prevent the cylinder from getting out of position. The cylinder *a*, *a* is supported by two end-frames, which carry the axes of the rollers *c*, *c*, *c*. The sifting surfaces *a'*, *a'* are fixed in the spaces between the longitudinal bars of the cylinder by means of turn buckles *d*, or other convenient means. Within the cylinder *a*, *a*, is suspended a hopper *e*, *e*, which is carried by the end-framings, as shown. Below the hopper are two crushing rollers *f* and *g*. The axes or necks of the roller *g* have their bearings carried by the end-framing, and the roller *g* is driven by steam or other suitable power, and when desired the roller *g* may be made suitable to be heated by steam or other means. The axes or necks of the roller *f* have their bearings in two weighted levers by which the roller *f* is kept pressed to the roller *g*; by these means the materials to be crushed and sifted being placed in the hopper, the same pass between the rollers *f* and *g*, and become crushed by the rotation of the cylinder *a*, *a*. Such crushed materials become sifted, and such portions thereof as do not pass through the sieve surfaces are raised up by the inclined shelf *i*; more than one such shelf may be used.

The above machine has been patented by Mr. Jobson.

GOVERNMENT RIFLES.

Gentlemen,—As we learn that the Enfield Rifles have in numerous instances proved utterly useless in the field in India, I shall be glad if any of your readers can tell us how the oval bore Lancasters, supplied by the Ordnance, have answered? Perhaps Mr. Lancaster himself would favour us with any authentic reports which may have been issued respecting his peculiar bore small arms.—Yours obediently, J. Bartery, Cheltenham, 4th April, 1859.

CUNNINGHAM'S NON-RECOIL CARRIAGE FOR NAVAL GUNS.

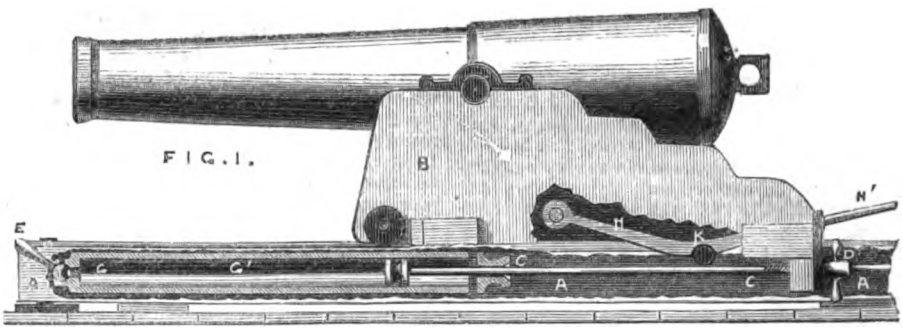

Fig. 1, *side elevation, partly in section. AA, the slide. BB, the carriage. GG', a tube fixed in slide. CC, piston rod attached to piston in tube, and connected with cannon by the screw lever at D. E is a valve by which the outer end of tube can be opened or closed. HH', is a gab lever to retain the gun from running out if worked in the ordinary manner, but this would not be required on the Non-Recoil Principle. Fig.* 2 *is an end view.*

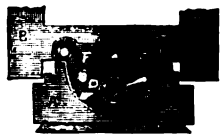
FIG. 2.



N.B.—The tube G is here shown exaggerated in size for the purpose of perspicuity.

[The following communication has been received from H. D. P. Cunningham, Esq., R.N., the inventor of the system of self-reefing sails which is now largely in use in the ships of all nations.]

Bury, near Gosport, 2nd April, 1859.

With reference to the probability of Sir William Armstrong's gun being used for ship's purposes, it is *à propos* to the subject to refer your readers to my plan for receiving the recoil force of a gun on the elastic medium of the atmosphere, as described in Number 1354 of the Mechanics' Magazine, 21st July, 1849, which I there term my atmosphere gun carriage, as I then contemplated working ordinary guns by the power which I economise by my arrangement.

The necessity of running the carriage in and out for the purpose of loading the gun no longer exists in a breech-loader. It is desirable, therefore, to have the carriage of a gun of this description on the *non-recoil* principle, as by this arrangement the time occupied in running out the carriage by the side tackles is saved, and hence the gun worked with greater speed and fewer men. A very serious objection, however, exists to a carriage on the non-recoil plan, and that is the great shock which it gives to the ship's side, and indeed to the whole fabric. A remedy for this is to receive the shock of recoil on some elastic medium which will yield sufficiently to blunt or deaden the effect of the shock. Now this is provided for in my plan.

Using a carriage on the slide principle, I place in the slide a tube of sufficient length, within which are fitted a piston and rod. The outer end of the tube is furnished with a valve, and the inner end has orifices for the admission of air. The carriage is connected with the piston rod by a screw capable of ready disconnection, and also re-adjustment. When the gun is fired, and caused to recoil, the piston is of course carried with it down the tube against the pressure of the atmosphere (the valve at the outer end being closed), and thus a retarding force is exercised which, increasing with the distance travelled, finally overcomes the force of recoil, and the reacting result is that the gun is driven out again. By opening the valve at the outer end, the vacuous action ceases, and the carriage can be used as an ordinary one. This valve also regulates the amount of resistance, as by admitting a certain amount of air, the purity of the vacuum is affected, and hence the amount of atmospheric pressure diminished. This valve can also be made to act the part of a train tackle, to prevent the gun running out if required to be kept in; in this case, the gun having been run in with the valve open, the tube is filled with air. On the shutting of the valve, this column of air offers a resistance to the passage of the piston down the tube; hence the carriage cannot run out in that state. There are also other purposes that can be secured by the action of thi tube.

I have never received a copy of the report of the select committee at Woolwich, before which I was ordered to appear with my plan, but I remember that the President laboured under the impression that it was on the principle of *compressed air*, and that the result would be ignition of the carriage, an opinion which I earnestly combatted, but I am afraid without success. I avail myself of this opportunity to point out that the air is *not compressive*, the tube being open at the inner, or baroscopic end, and the weight of the atmosphere only is the resisting force exercised in controlling the recoil of the gun. I repeat that I believe my plan of receiving the shock of recoil on the elastic medium of a vacuum in the very simple manner provided by me, is admirably adapted for guns worked on the non-recoil principle, which, I presume, will be the case should Sir William Armstrong's gun become in use for naval artillery.

It was in working out the design of a breech-loading cannon that I was led to devise the plan I have here described for perfecting a carriage on the non-recoil principle; and it was in course of considering the subject of breech-loading guns that a most formidable objection to the use of this description of ordnance for ships' purposes presented itself, and which I consider most important. This objection consists in the danger of the fire in the gun blowing in-board on opening the breech when fighting or working weather guns, or guns on the windward side of the ship; an objection which also applies to casemated batteries, although not so important as with reference to ships. So long as cartridges made of inflammable material are used I do not see how this objection can be prevented. Whatever arrangements may be made for opening the breech, if any fire exists in the gun when the breech is opened in-board the fire must blow; and the result of having a large quantity of fire thus scattered about the decks in action may be easily appreciated by naval men. Whether cartridges can be made of inflammable materials, so as to retain that state after the firing of the gun, is a subject for the consideration of chemists. My idea is, that any textile fabric subjected to the penetrating effects of the explosion of gunpowder, however in its original state it may have been rendered inflammable, will imbibe so much of the igneous particles of the gunpowder as to inflame when brought into contact with the air. I believe this to be a most important consideration in connection with the Armstrong gun, and an objection that must be overcome before this weapon can be used with safety on board of ships.

I enclose you a plan of my atmospheric gun-carriage. I remain, your's obediently,

H. D. P. Cunningham.

IMPROVEMENTS IN FISHING TACKLE.

WE have had occasion more than once recently to call attention to a movement amongst the fishing-tackle makers that has for its object the improvement of a business which was becoming fixed and stationary, or rather to adopt the notion that in these days "to stand still is to go back," was retrogressive. Mr. Little, of Crooked-lane, took the lead in this forward inclination, and in 1851, at the Grand Exhibition, showed us very many improvements in the ordinary fly, trolling, and spinning rod. Then followed men from Worcester and elsewhere, who would catch the public if they did not catch any fish, with artificial baits that were purposely made not to break the second commandment, so unlike were they to anything on the waters, or out of them. Crooked-lane then aroused itself, and several minor novelties, if not improvements, were consequent; and then the dream of the seven sleepers came over all, and the trade dozed again. This season, however, one of the craft, Mr. Wright, of 376 Strand, has started from his slumbers with a whole creel full of artful dodges—the word is now used in Parliament—having for their object the capture and destruction of the finny tribe. Amongst these is a new bait, which cannot be termed artificial, as it is composed of the veritable gudgeon or dace itself, stuffed in its own skin, and varnished with a hard transparent cement; this latter and its eyes, if we except the hooks with which it is armed, are the only unreal things about it. We pity the salmon, the trout, the pike, or the perch, ensnared by so crafty a bait. These victims may find in it something to add to the already overwhelming charge of the treachery of man; and man himself, in a philosophic mood, may see in it an instrument to determine the long-mooted question, whether the sense of smell is active in fish, and influences the selection of their food. Another novelty is in a garf, or sanding hook, which is incapable of doing any mischief to its owner when not in use. Another is a reel for deep-sea fishing. A fourth, a disgorger with a handle for pike, and other large-mouthed fish. A fifth is an acorn-shaped ferrule-stopper, giving a hold and purchase to the fingers for their removal, more particularly in cold weather, and indeed several other affairs, apparently trivial in themselves, but important to those whose holiday life takes its charm and colour from the sports of the stream.

A PLAN FOR IRON DWELLING-HOUSES.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—I beg to submit the following thoughts about incombustible dwellings for your consideration:—

No one needs to be told that the use of easily combustible materials—such as wood—in the construction of houses is a great evil: the only question to be asked is, How is it to be avoided? The "fire-proof" mode of building would, doubtless, be generally adopted but for the increased expense. Iron has been proposed as an economical material, and, as immense strength is given to very thin plates of this metal by simple corrugation, it may be well worth inquiring whether something more than the public is at present aware of may not be done by its employment. We will suppose the walls to be built of the usual double-plating, with some non-conducting substance, as felt, cork, or wood, sawdust, &c., interposed; and then the question arises, Of what use are incombustible *walls*, if the house may be at any moment gutted by fire?

Suppose, then, that a jointing of iron tubes, consisting simply of "plate," no thicker than experiment shall show to be necessary in reference to the span, were to be substituted for wood; over these a flat plating might be laid, and the thing is done. The edges of the plates might be tinned, which, on the grand scale, is a very simple operation, and so secured with a little solder, containing, for cheapness sake, as much lead as will "give" to the soldering-iron (if, indeed, the oxy-hydrogen blowpipe be out of the question, which I think a needless supposition, and the use of which instrument would of course dispense with the more expensive metal *tin* altogether); and thus we can imagine a habitable room, with the incombustible character of which we are in search. It is possible that, instead of joints, as described above, a simple succession of corrugated plates might be cheaper, and equally effective; but the power which corrugation gives of applying *light* metal plates to sustain heavy weights, is one which, I think, will in the long run, turn the scale in favour of iron dwelling-houses, at least for the poor, and in places where *use* is the object in view. I can see no reason why a roof of galvanized corrugated iron, eschewing all timber, slates nails, &c., should not be a very safe and economical substitute for that we hear now constantly spoken of as the great bugbear, the monster difficulty in building.

I am, Gentlemen, only an engineer; but I can assure you that I represent a very numerous body of non-professional readers, to whom a little information on the subject would be very acceptable. Could not you, or some one of your many valuable correspondents, give us a comparative estimate of the probable cost of such a roof for a cottage, or small house, as I have described, as compared with one of timber and slates of the usual kind? The general impression appears to be, that the introduction of iron into house-building would interfere with a vast number of trades and professions now flourishing, just because the ordinary materials are employed; and that this is the reason they hear so little about it.

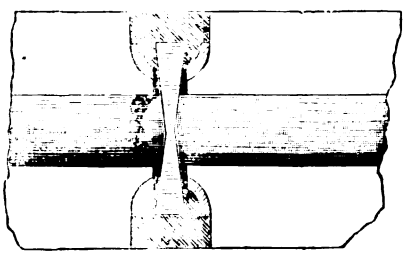
I know not how this may be; but I think I could scarcely start a better subject for inquiry and solution in your excellent journal, than that which I thus venture to bring before you.

I remain, Gentlemen, your constant reader,

PLATO.

CAPTAIN NORTON'S FUZE.

CAPTAIN NORTON writes:—"I shall be much obliged if you will be so kind as to give a place in your next Magazine to the enclosed drawing of a section of my concussion-fuze, representing the rivet having the molten lead poured into the metal cups at each end of the connecting fuzible band of sheet zinc. In your number for the 12th of June last, you kindly gave a drawing of a section of my fuze, showing the metal cup placed



on one end of the connecting band. The present drawing will, together with the former, make all intelligible. Before the molten lead is poured into the cups, a cuirass of steel is placed over the cup, and the lead is poured in through a funnel saucer-shaped in form, like the steel cutter on the upper end of a bullet mould; when the lead is cool, a gentle blow on the end of the cuirass cuts the lead level with the surface of the fuze-case."

THE ATLANTIC CABLE.

GENTLEMEN,—I am at a loss to conceive on what grounds the *Times* of this day repeats the opinion expressed in a former article that, "when a fresh wire is laid the old cable will possess an undoubted value for the return current," thereby setting up a wire of (I believe) less than ¼-inch diameter in comparison with that wire, the earth, which has a diameter equal to its length, and which, therefore, offers no resistance to the passage of the return current. I can only presume that the writer has run away with the idea that by placing two wires side by side—one of which, for the advance current, is a pretty good one—he will obtain exemption from the so-called earth currents which have been the scapegoat for the failure of the electricians in sending signals along the present Atlantic cable. To those common minds who have not yet made acquaintance with those mysterious currents it may appear possible that the signals on the telegraphic instrument alluded to in the *Times'* article of the 3rd Feb. last, 83rd line, may have been only the result of that electric condition set up by the intense electricity employed by her first operators and the use of which cannot be too strongly reprobated. Those "constant and perplexing vagaries" called the earth currents may appear to such minds as simply the discharge of a cable which had had too much electricity of an intense kind sent into it. If such be the fact, it is difficult to understand in what way the present cable can be of any use in the manner indicated. That it will be made to work I am confident, but it will be by means far different from those pointed out by the writer, who will, perhaps, should this meet his eye, enlighten your readers on the points referred to, as the paper to which he has contributed his ideas would possibly not have permitted me to question its writer's judgment.

Your's, respectfully,

17th March, 1859. S. B.

DESTRUCTIVE ENGINES OF WAR.

WE have received the following letter from Mr. Macintosh, the inventor of those formidable means of warfare which have been the subject of remark in these columns:—

GENTLEMEN,—In reference to your remarks on Dr. Lardner's letter in your last impression, touching a question of surpassing importance to us as a nation, and pointing out that the introduction of chemical agents into her Majesty's service would greatly augment our powers of destruction, permit me to make a few remarks, to which I trust you will kindly give insertion. In 1852, with a view of introducing into the service compounds of kakodyle as an agent of warfare, I filled small diaphragm shells (having a bursting charge) with the chloride, cyanide, and oxide of kakodyle. These shells, on bursting, ignite spontaneously, setting fire to everything combustible. The result of this combustion is the evolution of clouds of white arsenic, so that the atmosphere round becomes poisonous. I have also filled shells with cyanogen gas, in combination with arsenic and with hydro-cyanic acid. By the explosion of such shells the surrounding air would be instantly impregnated with vapour of the most fearful poisons known. To the reader, it may appear difficult to conceive a collection of more formidable properties, or of a more fitting agent of destruction, were it not for the following drawbacks to its practical application, viz.:—1. The great difficulty and danger of preparing and stowing it. 2. Its efficiency would entirely depend on the shells bursting in confined places, where nere is little draught of air, as the diffusive properties would rapidly neutralise its useful effect. 3. t will not burn on water, being specifically heavier, having a density of 1·462. 4. In case of leakage it would be formidable, as well to friends as foes.

To obviate these difficulties, I substitute for kakodyle, coal tar naphtha, bisulphuret of carbon, and phosphorus, which can be had in any quantity, and applied without danger.

These shells on bursting ignite spontaneously, setting fire to everything combustible, and rendering the air pernicious to life. J. MACINTOSH.

April 6th.

THE METROPOLITAN BOARD OF WORKS.

GENTLEMEN,—Some months ago the rate-payers of London were greatly startled at the wonderful business-like movement, all in a moment, of the Board of Works announcing the names of several leading engineers to send in for their approval plans and models to raise all the sewage on the Lambeth side of the river. Well, of course one would have thought from such a flourish of trumpets the thing would have been done off hand;

Digitized by Google

what do we find, however? Instead of that the Main Drainage Committee then appointed to carry out the works forthwith, are actually thrown overboard and the whole board substituted in its place. Now, gentlemen, if they would only do the work they ought to do as fast as they do and undo themselves, there would yet be hope; but as things proceed at present, if ever a reform was wanted in anything in this world it is in this body. If the parishes who send such refractory members would only advise them to stay at home, something might be done; positively it would be better for us all that such men were paid to lie in bed. Unfortunately I am a large rate-payer, and must pay whatever demand they make, but even then it would be a little consolation to see our representatives conducting themselves as sober men of business. I am, Gentlemen,

An Ill-used Rate-payer.

GUNNERY.

An esteemed correspondent sends us the following suggestive remarks:—"There are facts connected with this interesting subject which I think are very little known, and this is my excuse for troubling you with these observations. Doubling the weight of a gun, keeping the same diameter of bore and firing it with the same charge of powder as the one of half its weight, will give seventy five per cent less recoil, and a projectile force of about twenty-five per cent. more Not allowing any recoil with the same increased weight makes a still greater augmented effect. These advantages would be surely of great moment in the employment of guns for maritime purposes, and especially when breech-loading guns are used; as guns without recoil on a substantial breech-loading principle could be fired four times for once as compared with guns on the old principle; so that with half the number of guns employed, there would be no more weight on board, but immense increased operative effect would be produced.—J. M.

ASSOCIATION OF FOREMEN ENGINEERS.

At the meeting on Saturday, April 2nd, Mr. Joseph Newton in the chair, Mr. Theyte read a paper on the "Best Means of producing Heavy Castings in Iron." The subject was one which the great practical experience of the writer of the paper enabled him to deal with in the most lucid and satisfactory manner. He explained, in language divested of technicalities, the best methods of making patterns, moulds, and castings, whether for hydraulic rams, cylinders, or any other articles requiring strength and density. The paper was illustrated by diagrams carefully prepared, and was listened to throughout with much attention and interest. A vote of thanks was, at its conclusion, unanimously given to Mr. Theyte.

It was announced by the chairman that Mr. John Briggs would, at the ensuing May meeting, read a paper on the "Concussion of Water."

NORTH OF ENGLAND *v.* WELSH COAL.

The reports of Messrs. Miller and Taplin to the Board of Admiralty on the evaporative power and economic value of Hartley coal, and on the properties of Welsh steam coal, are now before us. From the average results obtained in their experiments, and from their general observations, they come to the following conclusions:—

First. That when the smoke from the north-country coal is consumed, its evaporative value is nearly equal to that of Welsh coal, while its rapidity of combustion is greater, and therefore that it is capable of generating a larger quantity of steam in a given time.

Second. That from the harder nature of the north-country coal, it is less liable to be broken up from motion than Welsh coal, and from the large heaps which had been exposed at the pits' mouths for nearly twelve months, which we saw at some of the collieries, without exhibiting any symptoms of falling into small particles, thereby showing that atmospheric changes had but little effect upon it; and therefore, for these reasons, it is better adapted for store or conveyance to distant parts of the world than Welsh coal, which from daily experience is found not only to be greatly reduced in size by motion, but to be reduced to dust when exposed to the changes of atmosphere in stores, &c. These comparisons are only made upon the supposition that the smoke from north-country coal may be reduced to the same minimum as that which may arise from Welsh coal, or be entirely prevented by Mr. Williams' or some effective apparatus for this purpose.

Third. That it is possible to consume the smoke arising from north-country coal by the use of Mr. Williams' apparatus, and by the modification of it as introduced by the association to some of the collieries in this part of the country and elsewhere.

Messrs. Miller and Taplin are, we may state, assistants to the Chief Engineers and Inspectors of Steam Machinery in Portsmouth and Woolwich Dockyards respectively.

CAPTAIN KYNASTON'S LIFE-BOAT HOOKS.

Captain Tarleton, C.B., of H.M.S "Euryalus," in a letter from Alexandria, states that a seaman of that ship owes his life to the "Patent Slip-hooks." The day before the frigate arrived at Alexandria, when running eight knots, with studding-sails set, a seaman fell overboard. While the ship was in the act of rounding-to, and still held her way, Captain Tarleton ordered one of his quarter-boats (a 28 feet cutter), which was fitted with the "patent hooks," to be at once lowered with her crew. Although the boat happened to be the weather boat, and therefore most exposed to the wind and sea, Captain Tarleton adds, she was admirably disconnected, and the man picked up. The Pacha of Egypt had expressed his desire to see the working of the "hooks" on board his yacht when the weather moderated.

Law Case.

NORTHERN CIRCUIT.—LIVERPOOL, April 2, 1859.

Before Mr. Justice Byles and a Special Jury.

MACNEE AND OTHERS *v.* NIMMO.

Mr. Monk, Q.C., Mr. Hindmarch, and Mr. Ovens appeared for the plaintiffs; Mr. James Wilde, Q.C., Mr. Manisty, Q.C., and Mr. Ffooks for the defendant.

This was an action directed by the Lords Justices to try whether certain printed cotton fabric called "zebras," were an infrigement of the plaintiffs' patent. It appeared that there was an original fabric woven with coloured threads called "zebras," and that the plaintiffs, in order to imitate them, had invented a species of fabric woven with uncoloured threads, which were afterwards printed, and to make the resemblance nearer, there were in the plaintiffs' goods certain loose or "flushed" threads purposely woven at the back bearing an appearance very similar to the original zebras. These goods were the subject of the plaintiffs' patent. The defendant's goods were similar in some respects to the plaintiffs'. The difference, it was contended, existed in there being a pattern or raised figure woven on the face of them and the threads at the back, though loose or "flushed," as the plaintiffs' were, being also like the face woven into a pattern; the flushing being only so much as was necessary to produce that pattern. For these goods the defendant had taken out a patent; the question was whether the goods were substantially similar to the plaintiffs.

The trial lasted for some hours, and ended in a verdict for the defendant.

THE ARMSTRONG GUN.

In one part of the *Morning Post* we read that at Woolwich—"Sir W. Armstrong's gun, after a succession of trials, has been removed from the garrison to the Royal Arsenal, where it has been carefully stored, with strict orders that no person, whether connected with the establishment or otherwise, shall be allowed to view it without a special order for that purpose." In another we are told that "Discoveries in these days gravitate to the best market. Months ago, the whole secret of the Armstrong gun was sold by two malcontents to the governments of France and Austria." Moreover, a minute description of the Armstrong gun, a few weeks ago, went the round of the papers. Does not the Royal Arsenal at Woolwich resemble a stable, and is not the secret of the Armstrong gun like a horse, and the precaution of preventing any unauthorised person from viewing that invention, very much like the providence of closing the entrance of the quadruped's abode, at a period subsequent to the felonious abduction of the noble animal?—*Punch.*

FRENCH PATENT LAW.

A Paris correspondent, under date 30th March, writes:—The Corps Législatif is busy with the new patent law which has been so long anxiously looked for. The Bill under consideration includes many important amendments of the law of 1844, but retains some of its vexatious provisions; *e.g.*, the clause forbidding the importation of articles patented in France, except when the minister of public works shall grant a permit for the introduction of models of *machines*, and articles manufactured abroad and destined for public exhibitions or trials authorised by government. This article is now stringently enforced, the importation of all models except of machines being strictly prohibited—a serious obstacle to the working of patents for foreign inventions, the sale of which would be greatly facilitated by the patentees being allowed to exhibit their inventions in a complete form. Power is to be given to the government to regulate by an imperial decree the conditions of keeping inventions secret, and of "expropriation" for public purposes, the mode of publishing specifications and registering transfers, the attributions of a committee of consultation on questions relating to patents, &c., which includes the object proposed to be attained by the Bill now before Parliament. Meanwhile the Société d'Encouragement has published a specification in imitation of those issued by the English Commissioners, with the view of urging the government here to adopt a similar plan. A paper read by M. Laboulaye points out the utter uselessness of the present mode of publication:—"At long intervals, two or three years after the time when the patents might be published, appears a ponderous and costly quarto, containing a multitude of patents more or less mutilated (sometimes the only indication is, such an invention *is described in the patent*), without any order, and on all sorts of subjects—any one interested in one or two questions who might wish to consult five or six patents, naturally refrains from losing his time in searching through these volumes, and avoids purchasing them, thus this costly publication is in reality almost completely to no purpose. It has now become customary when any one wants to examine an important patent, which has as such been protected in England, to send for a copy of the English specification, which costs 1s. and two penny stamps; such is now the simplest means of examining a *French* patent."

BONELLI'S ELECTRIC LAW.

At the meeting of the 7th ult. of the Académie des Sciences, M. de Senazcourt informed the members that M. Froment has completed important improvements in the electric loom invented by Chevalier Bonelli, director of the Sardinian telegraph, which figured at the Paris Exhibition of 1855, and a commission was named to examine it and make a report to the Academy. M. Chevreuil stated that he had been to see it at work, accompanied by the President of the Chamber of Commerce and other gentlemen, and had been astonished at the results obtained. The invention consists chiefly in replacing the Jacquard cards by a thin sheet of tin on which the design to be reproduced on the fabric is figured with varnish or isolating ink The beat up of the batten brings a metallic comb formed of small separate teeth into contact with the design, when some of the teeth touch the varnish of the design, and others touch the metal; and those teeth in contact with the metal alone give passage to the electric fluid supplied by a Bunsen pile, and convey it to the small electro-magnets with which they are connected by means of a thin copper wire. These electro-magnets act upon an equal number of small iron rods to keep them out of the way of the wires of Jacquard, while those teeth which come in contact with the varnish of the pattern are allowed to project against the wires of the Jacquard, to act upon them in the same manner as the cards now used. As a proof of the case with which new patterns can be applied, when the Emperor and Empress were lately visiting the *Ateliers* to inspect the loom, M. Froment, without interrupting the work, replaced the design in course of execution by a band of tin, on which he had written the words Napoleon III., which were seen to follow on the fabric, the flowers composing the first design.

A very cheap and simple apparatus for showing the phenomena of polarized light has recently been arranged by Mr. Bestall, of 82 Brook-street, Kennington-road, Lambeth; the chief merit and novelty consisting in the facilities thus afforded to young people and persons in the humbler ranks of life, for familiarizing themselves with the operation of scientific laws, from the study of which they have hitherto been debarred by the high price of the philosophical instrument manufactured for the purpose.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

CORRESPONDENT'S QUERY.

GENTLEMEN,—Could any of your numerous scientific readers inform me of any rule by which to find the amount of stability of cast-iron pipes to resist compression.

I am, yours,

March, 28, 1859. A SUBSCRIBER FOR YEARS PAST.

Our Weekly Gossip.

The Government Bill for granting patents for inventions in India, which passed the Legislative Council in July last, has received the Royal assent. The Bill in its original form was published in full in the MECHANICS' MAGAZINE for July 19, 1858; but it has since been somewhat altered in Committee. The complete measure, in its amended form, shall be published on an early occasion in our columns.

The Council of the Society of Arts have arranged for two Conversazioni during the present Session; the first, on Saturday, the 7th May, at the Society's house, the card for which will admit the Member only; the second, on Saturday, the 28th May, at the South Kensington Museum, the card for which will admit the member and two ladies, or one gentleman.

The Council of the Society of Arts have received numerous offers of support towards establishing the proposed Exhibition of 1861 upon a much more popular and extended basis than on the last occasion (1851)—sufficient to enable them to undertake, with confidence, the task of finding four-fifths of what they consider the necessary guarantee. If Her Majesty's Commissioners of 1851 will sign for £50,000, out of £250,000, and allow it to be announced that, provided this guarantee is completed by a given day, they will hold the Exhibition of 1861 on their own ground at South Kensington, the Council of the Society of Arts could be prepared to take upon itself the labour and responsibility of completing the necessary sum. "With railway facilities increased fifty per cent.; with a population not only much changed and much advanced, but increased twenty per cent., and with the consequent increase of capital to that extent, there cannot," the Council consider, "be any doubt that, with a little timely energy and co-operation, the proposed Exhibition of 1861 will become a great and splendid success."

The official reports of two highly interesting and instructive papers read this session at the Royal Institution are now before us. The first is on the newly-discovered ape, the gorilla, by Professor Owen; the second is on some grounds of dissatisfaction with modern gothic architecture, by Mr. E. B. Denison. The latter lecture has been written since its delivery from the notes used on the occasion, and is of much greater length than the usual abstracts of the Institution. It is in Mr. Denison's best—and therefore not his usual—style, and will well repay perusal.

Mr. T. E. Hignett has exhibited to the members of the Liverpool Polytechnic Society, a model of a raft to be used in case of shipwreck as a means of transport in shallow waters. It is the invention of Captain Burnett, and consists of rows of casks laid end to end, each row being secured between four spars running longitudinally, and fastened by ropes, the different sections being afterwards joined together by additional lashings, according to the size of raft which may be required, or that the materials may suffice to make.

A limited liability company is proposed for the erection of blast furnaces at Seaham Harbour. It is proposed to erect the furnaces to the south of the town, and the site for the works will consist of about 12 acres. Two furnaces are to be erected in the first instance, and two others are to follow if possible. The capital contemplated is £40,000.

The use of the Leeds Town-hall has been granted for the approaching meeting, in that town, of the Institution of Mechanical Engineers. There are to be three meetings and an evening conversazione.

M. Lauro Cecconi, a band-master residing in England, has just patented a method of constructing cornets, trumpets, horns, &c., with six pistons or cylinders for producing the tones and semi-tones, and for improving the intonation. These pistons or cylinders are so arranged that sliding tubes and crooks are dispensed with. He also employs various forms of simplified mechanism for operating the valves which regulate the notes in order that a simpler and lighter action may be obtained. His improvements have, we are informed, given to piston-instruments new and extraordinary powers of expression. Mr. Carte, the military musical instrument maker of Charing Cross, is manufacturing the new instruments, we believe.

Mr. J. H. Lindsey, of Grocers-hall-court, has introduced a method of applying loose plates to the covers of books for fixing the binding, and allowing one binding to be used for a series of books when required. The improvement will be valuable for some purposes.

As a curiosity for non-mathematical readers we give the following title of a paper read at the Manchester Philosophical Society by the Rev. T. P. Kirkman, M.A., F.R.S., viz., "On the *j*-nodal *k*-partitions of the *r*-gon."

An improvement in the method of producing copies of busts, statues, groups, and round ornaments by the galvanoplastic process has just been made public. The principle of the invention is the use of conductors so arranged as to spread the electrical current over a large surface. The modes of applying differ according to circumstances. One plan is as follows:—A piece of copper, or of charcoal, is made to represent in miniature the form in outline of the object to be reproduced; this miniature conductor is attached to the negative pole, and then introduced into the interior of the mould, which, of course, is in connection with the same pole; the whole is then plunged together in the bath. The metal is conducted by the various points of this miniature-conductor towards all the various hollows which correspond with its prominences. This, however, was but a rude form of the methods adopted. The inventor, M. Lenoir, afterwards substituted for the miniature above described, a light frame or mass formed of metallic wire or of any other conducting material, which he introduced in the same manner into the hollow of the mould: by this means he obtained a large number of conductors, which approached every portion of the interior of the mould, and formed what he calls a mass of nerves for conducting the electricity into the most intricate portions of the hollow mould. These wires also render the decomposition of the solution unusually active—so much so that the gas liberated rises constantly to the surface in large beads. The deposit, however, is made with perfect regularity and uniformity.

The *Mariposa Gazette* (California) gives an account of a new separator in use at Bear Alley, the property of Col. Fremont. This machine is described as working about a ton of mineral per hour, separating from it the whole of the gold free of mercury, sulphur, and the sulphurets. The quartz is reduced to a fine dry powder between stones, and in this condition is thrown upon a metal gauze, beneath which a strong current of air is created by means of bellows. The current is regulated so as to permit the descent of the gold, and to stop all the atoms of less specific gravity, which are immediately ejected so as not to encumber the action of the separator. Mr. Gilbert, the inventor, believes that the effect of air as a separating fluid is much superior to water, as the latter carries off some of the finely-divided gold. The reduction of the quartz and the separation of the gold without water or mercury is, we need hardly state, a great desideratum, and we shall be curious to see a machine separating the gold from its earthy companions by the same means that are used to separate corn and other grains from their accompanying impurities.

An interesting paper on the plans adopted for working and ventilating collieries in the Newcastle district, by Mr. Alexander Ross, of Gateshead, has been read before the Bristol School of Mines. Mr. Ross stated that two distinct shafts are now generally employed. In collieries of moderate extent, the downcast pit only is used for winding coals, but in more extensive works both shafts are used for this purpose. The shafts are generally placed in the centre of the estate to be worked, as this gives the largest area of coal which can be worked by one pair of shafts. The "pillar-and-stall" system of working coal is generally pursued. The size of the pillars of coal left in the ordinary workings is determined by the depth of the seam from the surface, the nature and texture of the coal, and the condition of the floor and roof, &c. At a depth of 60 fathoms from the surface, the ordinary pillars may be made 30 yards by 12; at a depth of 180 fathoms, 30 yards by 16 or 18; or in extreme cases, as the Monkwearmouth and Seaton collieries, where the seams are at a depth of 250 or 300 fathoms from the surface, 60 by 40 or 60 by 60. The paper, after entering into other details, added that furnace ventilation is nearly universal.

The Council of the "Bath and West of England Society for the Encouragement of Agriculture, Arts, Manufactures, and Commerce," (of which Society the Prince Consort has lately become a member,) taking courage from their prosperous condition, and the increased demand in the West of England for education and scientific instruction, have opened a new department of "Arts and Manufactures," for exhibition and sale. A special fund has been raised for a moveable building, to be used next year at Dorchester; a plan has been furnished by Mr. Nicholson, Agricultural Engineer, of Newark; and important local support has been obtained. Encouraging promises of articles for exhibition and sale have been received from London, the Midlands, and the North of England. The arrangements appear to be quite satisfactory to exhibitors. Pottery, glass, metal-work, wood-work, and textile fabrics will be there in attractive forms. It is said there will be a goodly show of water-colour drawings and sketches by West of England artists, and, in addition, a collection including works of Turner and others. The exhibition will open on the 30th May, and last for the week; unfortunately it is the week of the Derby. The entries close on the 16th April. The Committee of Council on Education have made a special exception in favour of this society, in order to allow the selection of decorative works of art from South Kensington Museum to be exhibited at the North Devon meeting, at Barnstaple—a meeting having for its object the promotion of the above-mentioned exhibition.

We are accustomed in this age to the utilization of much that was formerly considered waste material, but we scarcely expected to find any one patenting a process for the utilization of the metallic constituents of grindstone sand, or the detritus of the stones employed in grinding iron and steel manufactures. This, however, has been done. These sands, which are said to contain on an average from fifty to seventy per cent. of iron, steel, or a mixture of both, according to the source from which they are procured, are first freed from their earthy matter and oxides by washing, or by any known voltaic or magnetical separating process. The product of this operation, which consists entirely of finely-divided metal, is submitted to pressure in masses of convenient dimensions, which are afterwards dried. In this state the compressed metal is passed to the furnace, and heated till slightly softened, when the cohesion of the particles is completed by hammering in ingot moulds. These ingots are then returned to the furnace in superposed layers, according to the form and dimensions of the bars required, and are finely welded and hammered for use.

At the ordinary meeting of the Manchester Literary and Philosophical Society Mr. Binney made the following statement:—"In the public prints, frequent allusions are made to micro-photography. In the *Manchester Guardian* of the 11th March instant, is the following paragraph: 'Photographic Curiosities.—M. Amadio of Throgmorton-street, whose portrait of Charles Dickens no larger than a pin's point was lately noticed, has produced by photography a view of Westminster-bridge, the Houses of Parliament, and Westminster Abbey within a space not larger than the eye of a worsted needle. The same gentleman has published a portrait of a youth which is only just larger than a needle's point, but when magnified is as perfect as any conceivable likeness.' No doubt most of the members of this society have seen the beautiful specimens of micro-photographic art produced by one of our fellow-members, Mr. J. B. Dancer, F.R.A.S., during the last five years. So early as the year 1840 Mr. Dancer began his investigations on the subject, and soon produced satisfactory results on silver plates. In may, 1853, when Dr. Joule, F.R.S., and some other friends erected a tablet to the memory of our late distinguished member, Mr. William Sturgeon, the electrician, Mr. Dancer was so kind as to present me with a photograph of the tablet not larger than a pin's head. His discovery was not allowed to rest, for hundreds

Digitized by Google

of his beautiful specimens were sent all over the world. Within the last year or two several parties have coolly claimed Mr. Dancer's discovery, and when it is represented in a local print as something wonderful in M. Amadio having produced what Mr. Dancer did six years ago, it is only due to our fellow-member and townsman to set the public right as to who was the discoverer of micro-photography."

What has the MECHANICS' MAGAZINE to do with morality?—asked a certain gentleman a week or two since, when we happened, in mentioning an improved make of steel for crinoline, to put in a word against the abuses of that material. And we doubt not that when the present lines are read, some will wonder what we have to do with poetry. Well, we cannot avoid such questionings. No professional editors in existence adhere—we are prepared to contend—more closely than we to professional topics, and we do not intend departing from our custom in this respect. But surely we may, without offence, claim a little license—just sufficient to enable us to give a word of recognition now and then to such matters of morality, and even of poetry, as mere mechanism may bring directly under our eye. At any rate, in the exercise of that literary despotism which is the blessed prerogative of editors, we will do it, defying consequences. Why should we not? Here, for example, has fallen into our hands, by a strangely circuitous channel, a number of poems—or, to speak correctly, of verses—in honour of Sir William Armstrong, his excellent lady, and his wonderful gun,—all written by his workpeople. Why should we not give to these bards a word or two of favour, and to their songs a wider publicity than handbills and local journals can bestow upon them? We do not get an Armstrong gun every day. Of course we can only give a verse or two from each. These productions are four in number, and although they certainly embody far more feeling than fancy, they are not without a certain kind of merit. Two of them were sung by their authors at a feast given by Sir William and his partners, in the Elswick Works, Newcastle, to their workpeople. Of these, the first is by W. Ross, a fitter, and is entitled "The Armstrong Gun." The chorus of this meritorious piece is:—

> The Armstrong gun, the Armstrong gun—
> What a wonderful thing is the Armstrong gun;
> Sir William's invention astonish'd them a',
> Wi' his bolt for a shot instead o' a ba'.

This poet is mainly descriptive, and writes not a little in detail. Witness the following verses:—

> For to see our lish smiths in the smiddy sae thrang,
> Wi' their dark shinin' faces and good arms sae strang;
> Roun' the fire's glowin' heat how they bus'l and run,
> Weldin', hammerin', constructin' the new rifle gun.
>
> Our turners sae skilled, wi' lathes, silver clear,
> Revolvin', and turnin', wi' straps and their gear;
> The guns from their hands receive form and shape,
> The grooves are all cut—complete in their make.
>
> Nae spungin' or rammin' or servin' the vent—
> Sic things are no needed to serve its intent;
> In a neat little chamber, breach end o' the bore,
> Place the powder and shot, and awa' let it roar.
>
> Then there's fusees they're ca'd—sic wonders I tell—
> They 'splode the bolt shells when it pleases themsel';
> It's short range or lang range, it's a' the same thing,
> Just set them—they're true to the secret spring.
>
> The gunboats hae now lost their glory and pride,
> For our gun sends its bolts slap bang through their side;
> Neither iron nor oak can resist it ava,
> When it vomits them forth from its terrible jaw.

The next piece is by Mr. J. Sutherland, and is entitled "Sir W. G. Armstrong's Rifled Gun: a Terror to the World." The chorus is:—

> So success to Sir William, and long may he thrive;
> May his days be as glad as the bee in his hive.
> With his greatness of mind, he's had the patience of Job;
> He's now made a gun that can conquer the globe.

This bard is less descriptive than the other, confining his account of the gun's construction to the four following lines, which are, every line of them, perfectly correct—which poetry is *not* at all times:—

> This gun is a queer'un, it loads at the breech,
> They put a shell in, gives the screw a bit twitch;
> Then slap throo the groove away agoes the shell,
> What damage it dis there's ne man can tell.

He continues:—

> To improve his inventions he never will cease—
> This gun of Sir William's is sure to keep peace;
> It's an honour to Newcastle, the laurels he's won—
> With his hydraulic cranes and his wonderful gun.
>
> Some of the Admirals said the gun wadent de;
> It might de for land, but it wadent for sea.
> So they tried the gun with a bonny steel shell,
> Upon their strong battery—man, hoo it did tell!
> It went through the iron, the beam and the deck;
> It myed their great battery nowt but a wreck.
> And noo that aw've very near finished maw song,
> Here's a health to Sir William and Lady Armstrong.

But these authors, it will be observed, indulge in the very imaginative statement that the new gun has sent its projectile through the iron-plated batteries. We can pardon them that flight of fancy. The next effusion (signed "R. Sced,") is of a more military tone and spirit, and, to the tune of the "British Grenadiers' March," sings the praises of "Our Elswick Engineer":—

> Some talk of Colin Campbell and some of Pellisier,
> Of Raglan and Canrobert, and some of old Napier;
> But of all those valiant heroes there's none that can compare
> With the great Sir William Armstrong, our Elswick Engineer.
>
> What now are Minié Rifles, or the great Lancaster Gun,
> They sink to children's trifles, before the great A 1;
> Of all the warlike weapons that ever did appear,
> The strongest arm's by Armstrong, our Elswick Engineer.
>
> No more we'll skulk in trenches, or hide behind stone walls,
> But from the open plain, boys, beyond the reach of balls,
> We'll show'r destruction on our foes in distance far or near.
> Each shot and shell its tale will tell of our Elswick Engineer.
>
> In vain they fight, in vain they fly, nor need we them pursue,
> But keep them within range by the turning of a screw;
> On decks o'war our British Tars, will sweep the ocean clear,
> In freedom's cause, with loud hurrahs, for our Elswick Engineer.

The last of these productions of art is by Mr. Joseph Wilson, and is in honour of "Armstrong, the Pride of the North." We can only afford space for two verses from this, the most ambitious piece of all:—

> Hurrah for the pride of the North!
> Who's name hath appeared like a star
> Displaying its light o'er the earth,
> In glorious might from afar;
> Let us call him the pride
> Of the bright coaly tide,
> For through him, we may now defy war.
>
> Well may old England extol
> The eminent men it contains,
> To its list we another enrol,
> And to him we direct our strains;
> Let us then rejoice,
> And in praise raise our voice,
> To Armstrong, and wide be his fame.

We will only add to these poetic outbursts one sentence from a speech made at the feast by Mr. Rowell, Sir William's foreman of smiths. His observation may seem prosaic, but it was doubtless very earnestly made. He said, "They had met to celebrate the top-stone of Sir William's greatness; they had that evening surrounded the festive board at Sir William's own expense."

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated December 16, 1858.

2880. R. Wilson and R. Wilson, jun., of Manchester. Certain improvements in the preparation of leather in combination with india-rubber and other materials, for the manufacturing of hose pipes and other purposes where leather is required to be impervious to water, steam, or frost.

Dated February 19, 1859.

460. T. Earle, of Clapham, Contractor. Improved apparatus for conveying signals to railway trains in motion.

462. W. Basford, of Burslem, Brick Manufacturer. Improvements in the method of, and means for, drying bricks and tiles preparatory to their being burnt, and also in the construction of kilns or ovens for burning such bricks, tiles, pipes, pottery, or earthenware, and in the mode of charging or placing these said articles therein to be burnt or fired, and also in certain appliances for regulating the heat therein.

Dated February 25, 1859.

516. G. Peover, of Wilmington-sq., Mathematical Instrument Maker. An improved optical instrument, being an improvement upon the kaleidoscope.

Dated March 8, 1859.

600. J. King, of Moss Mill, near Rochdale, Cotton Spinner, and A. Wilcock, of the same place, Mechanic. Improvements in certain parts of machines used in preparing, spinning, and doubling cotton and other fibrous materials.

602. W. Halliday, of Wakefield, Gentleman. Improvements in apparatus for preventing smoke and economising fuel.

604. C. Mills, of Camden Town. Improvements in the action of pianofortes.

606. E. Deane, of Arthur-st., London Bridge, Gas Engineer. Improvements in apparatus for the transmission of gas and other fluids.

608. B. M. Belling, of Bayswater, Dentist. Improved apparatus for hardening india-rubber for the bases of teeth.

Dated March 9, 1859.

610. J. A. Williams, of Baydon, Wilts, Farmer. Improvements in machinery or apparatus for cultivating land by steam power.

612. J. R. Nicholson, of Redditch, Doctor of Medicine. New or improved machinery to be used in the manufacture of needles, a part or parts of which said machinery may also be used for pointing pins and other like articles.

614. G. C. Pearce, of Cyfarthfa, Glamorgan, Engineer. An improvement in cornets, trumpets, trombones, and other like wind instruments.

618. W. E. Newton, of Chancery-lane. Improvements in billiard tables. A communication from A. Bassford, of New York.

Dated March 10, 1859.

620. J. C. Martin, of Barnes, Naval Architect. An improvement in the manufacture of cannon and small fire-arms, and of projectiles to be used with the same.

622. R. F. Woodward, of Birmingham, Manufacturer. An improvement or improvements in the manufacture of certain kinds of scale beams and fittings used therewith.

Dated March 11, 1859.

624. J. H. Burton, of Enfield Lock. An improvement in breech loading fire-arms.

630. A. V. Newton, of Chancery-lane. An improved construction of steam-engine, applicable also to the raising of water. A communication from S. Hube.

Dated March 12, 1859.

632. W. E, Newton, of Chancery-lane. An improvement in endless chain propellers for boats and other vessels. A communication from A. Wolcott, of New York.

638. R. Allison, of Birmingham, Engineer. Improvements in apparatuses for boring and sinking.

Dated March 14, 1859.

640. R. Waller, of Baker-st., Portman-sq., Gentleman. Improvements in joining leather, flexible and textile materials, for the production of boots and shoes, and articles of the like description, and harness, strapping, bags, sails, tent-covers, portmanteaus, and such other articles, together with machinery and apparatus for that purpose.

642. A. Tylor, of Warwick-lane, Newgate-st. Improvements in apparatus for regulating the supply of water to water-closets and other vessels.

644. D. Joy, of Leeds, Engineer. Improvements in hydraulic engines and meters.

646. E. Smith, of Dudley-port, Stafford, Agent. Improvements in treating or preparing furnaces used in the manufacture of iron.

648. J. S. Dawes, of Smethwick, near Birmingham, Gentleman. A new or improved method, or combination of arrangements for the better securing and collecting of night-soil or town manure, and rendering it more valuable for agricultural purposes.

Dated March 15, 1859.

650. C. Desurmont, of Seclin, France, Gentleman, and C. Goudeau, of Alost, Belgium, Mechanical Engineer. Certain improvements in looms for weaving.

652. C. Ritchie, of the Strand, Engineer. Improvements in calculating machines.

654. B. Rider, of Red Cross-st., Boro', Leather Dresser. Improvements in hats, caps, and other coverings for the head, and in the apparatus used in the manufacture of such articles.

Dated March 16, 1859.

655. J. Dixon and R. Clayton, of Bradford, Engineers. Improvements in rolling iron and steel for manufacturing railway wheels and for other purposes.

657. W. Robertson, of Dundee, and J. G. Orchar, of the same place, Engineers. Improvements in weaving.

659. J. Parker, of Camberwell, Solicitor's Clerk. Improvements in lever-sails, and in submerged feathering-propellers.

661. F. Mordan, of Goswell-road, Manufacturer. A means of keeping a stopper connected with a bottle, jar, or such like receptacle when removed from the mouth thereof.

663. J. Fuller, of Reading, Turner. Improvements in churns.

665. J. Michel-Denys, of Charleroi, Belgium, Gentleman. Certain improvements in the construction of railway crossings.

669. G. Hamilton, of St. Martin's-le-Grand, and W. H. Nash, of Poplar, Engineer. Improvements in tumbler or lever locks, and in keys for such and other locks.

671. T. W. Miller, of H.M. Dockyard, Portsmouth. Improvements in blocking or securing ships and other vessels whilst being removed, examined, or repaired.

Dated March 17, 1859.

673. C. Garnett, of Cleckheaton, York, Machine Maker. Improvements in machinery for ginning cotton, and for cleaning cotton and certain other fibrous materials.

675. E. T. Hughes, of Chancery-lane. Improvements in machinery or apparatus for crushing sugar-canes and other materials. A communication from S. Thérèse.

677. T. Skelton, of Plaistow, Draughtsman. Improvements in steering apparatus.

679. P. Larochette, aîné, of Paris. Improvements in machinery for brewing.

681. A. Warner, of Threadneedle-street., and W. H. Tooth, of Southwark. Improvements in the manufacture of iron.

Dated March 18, 1859.

683. W. Cook, of Hull, Coppersmith. A smoke consumer.

685. Sir W. G. Armstrong, Knight, of Newcastle-on-Tyne, Civil Engineer. Improvements in the means of igniting explosive projectiles.

687. J. Molesworth, of Rochdale, Gentleman. An improvement in telegraphic communication. A communication from F. N. Gisborne and F. O. J. Smith.

689. J. Hinks and G. Wells, of Birmingham, Manufacturers. A new or improved pen-holder.

691. R. Mushet, of Coleford, Metallurgist. An improvement in the manufacture of cast steel.

693. C. Lambert, of Sunk Island, York, Farmer. Improvements in corn and seed drills.

Dated March 19, 1859.

695. T. Allen, of Waingate, Sheffield, Clothier. Improvements in petticoats.

697. E. L. Benzon, of Sheffield, Steel Manufacturer. An improvement in the casting of steel. A communication from E. Riepe, of Pau, France.

Digitized by Google

699. H. Whitaker, of Newman-st. A new musical instrument, to be called "The Cherubine Minor."
701. W. Haigh, of Reddish, Paper Maker. An improved manufacture of paper, to be employed for the purpose of packing and other similar uses.
703. R. Mushet, of Coleford, Metallurgist. An improvement or improvements in the manufacture of cast steel.
705. A. V. Newton, of Chancery-lane. Improvements in propelling vessels. A communication from T. W. Phinney.

Dated March 21, 1859.

707. W. Haggett, of Sherborne, Dorset, Architect. An improved method of treating metals and other materials to increase their strength.
709. W. Hudson, of Burnley, Meahinist, and C. Catlow, of the same place, Overlooker. Certain improvements in looms for weaving.
711. G. Ferguson, of the Strand, Naturalist. The combination and application of certain materials for the destruction of insects and vermin.
713. S. Leoni, of St. Paul-st., Manufacturer. Improvements in the manufacture of useful and ornamental articles, surfaces, and works, parts of articles and parts of machinery or apparatus, from talc and other silicates of magnesia, and from the same combined with other substances.
715. G. Gregg, of Sheffield, Currier. Improvements in currying or manufacturing leather.
717. W. Rhodes, of Bradford, Whitesmith. Certain improvements in fire-proof safes.

Dated March 22, 1859.

719. J. Davis, of Frith-st., Soho, Professor of Music. Improvements in musical instruments.
721. W. A. Gilbee, of South-st., Finsbury. An improved apparatus for stretching and polishing silk thread. A communication from Lyonnet and Prenat.
723. F. Ashford, of Commercial-road-east. Improved means of fastening and securing treasure or bullion cases.
725. E. Maynard, of Washington. Improving breech-loading fire-arms.
729. Sir P. Fairbairn, of Leeds, Knight, and R. Newton, of Leeds, Commercial Traveller. Straightening and separating the fibres of silk waste, and laying them in parallel lengths preparatory to combing or dressing.
731. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in fire-arms and ordnance, and in projectiles and apparatuses to be employed therewith. A communication from C. Rochaz, of Paris.
733. A. Watkins, Brush Manufacturer, of Greek-st., Soho. Improvements in the manufacture of brushes.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

780. W. Mossman, of Pentonville, Stationer. Improvements in machinery applied to embossing or cutting presses, for the better and more expeditious manner of manufacturing ornamental cut out and embossed work, in paper, leather, parchment, cloth, foil, and other material. Dated March 29, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, April* 5, 1859.)

2678. F. H. Maberly. Candlesticks.
2680. F. Loss. Gas regulators.
2696. J. Ramsbottom. Water meters, &c.
2702. G. B. Sander. Jugs.
2704. S. Diggle. Weaving.
2706. L. A. Possoz. Alkalies.
2712. G. Hadfield. Carboys, barrels, &c.
2716. W. A. Henry. Boots and shoes.
2723. D. Evans and G. Jones. Pumps and water guages.
2729. J. Thow and T. M. Hall. Furnaces.
2731. G. Boccius. Furnaces.
2742. J. Samuel and J. Nicholson. Steam-engines.
2743. E. Viney. Portmanteaus, desks, &c.
2752. J. Lewis. Attaching sails to the yards.
2758. J. Tyssen. Motive power.
2770. H. Beven. Effecting arithmetical operations.
2773. L. W. Fletcher. Telegraph cables.
2779. J. B. A. Monnier. Railway brakes.
2790. J. and F. Muir. Colour printing.
2795. F. W. Fletcher. Bolts.
2830. E. L. Pensuete. Driving piles.
2874. C. F. Vasserot. Marine engines. A communication.
18. I. Wood. Corks. A communication.
86. R. and W. Hawthorn. Promoting combustion and preventing smoke.
284. R. Needham. Water-guage.
289. R. A. Brooman. Sewing machines. A communication.
446. T. Cattell. Treating gutta percha.
491. W. Ashton. Gas regulators.
546. J. T. Carter. Preparing fibrous materials.
577. C. R. Mead. Water gas meters.
592. W. Palmer. Carriage break and coupling.
613. J. Erwood and J. Skertchly. Glass, sand, and emery papers.
615. J. S. Russell. Building ships.
630. A. V. Newton. Steam-engine. A communication.
639. J. Macnab. Telegraphing apparatus.
642. A. Tylor. Regulating supply of water.
705. A. V. Newton. Propelling. A communication.
729. Sir P. Fairbairn and R. Newton. Silk waste.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 1, 1859.

2194. W. Brierley, sen.
2198. J. C. & E. W. Holman.
2206. J. Mills.
2207. A. Bessemer.
2209. W. Menelaus.
2211. J. H. Brown.
2213. J. H. Brown.
2219. G. Collier.
2223. W. Malam.
2225. C. Baylis.
2230. D. Naylor.
2248. A. E. Galliard.
2251. L. Hope.
2292. W. Clark.
2296. T. Archer, jun.
2303. T. Moore.
2307. G. F. Wilson.
2364. R. Kennedy and J. Armstrong.
2372. W. E. Newton.
2376. J. J. Welch and J. S. Margetson.
2386. S. R. Parkhurst.
2406. A. Heywood.
2409. W. Munro.
2436. W. Palmer.
2439. M. A. F. Mennons.
2879. W. Morgan.
2987. T. Bell.
68. E. Cobbold.
147. W. Newman.
219. H. Rawson.
250. J. Buckingham and G. Salt.
302. J. Buncher.
326. P. Adie.
352. E. Bagnicki.

Sealed April 5, 1859.

2137. A. F. Jarloureau.
2212. G. Hamilton and W. H. Nash
2217. J. Luis.
2226. D. Nicoll.
2229. J. C. Nouveau.
2234. J. Luis.
2243. C. W. Lancaster.
2252. W. Crofts.
2301. W. Bacon.
2337. R. A. Brooman.
2398. T. Almond.
333. R. Tinkler.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

770. B. Looker, jun.
786. J. Gray.
801. J. Samuel and J. Nicholson.
818. C. W. Ramié.
820. J. G. Martien.
827. J. Bernard.
833. F. G. Underhay.
838. E. Leigh.
902. W. Fuller.
908. A. V. Newton.
915. H. Y. D. Scott.
923. W. Tytherleigh.
989. F. W. Blacket.
1024. J. Rigby.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1849, 1890.
BOILERS AND THEIR FURNACES, 1903.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1849, 1869, 1892, 1894, 1902.
SHIPS AND BOATS, including their fittings, 1881, 1913, 1918.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1817.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1850, 1851, 1856, 1857, 1864, 1876, 1886, 1899, 1904, 1905, 1906.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING. *None.*
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1855, 1865, 1872, 1873, 1917.
METALS, including apparatus for their manufacture, 1859, 1898.
CHEMISTRY AND PHOTOGRAPHY, 1896, 1910.
ELECTRICAL APPARATUS, 1848, 1866, 1889, 1900, 1916.
WARFARE, 1854, 1871, 1875, 1879, 1911.
LETTER PRESS PRINTING &c., 1852.
MISCELLANEOUS, 1853, 1858, 1861, 1862, 1863, 1867, 1868, 1870, 1874, 1877, 1878, 1880, 1882, 1883, 1884, 1885, 1888, 1891, 1893, 1895, 1897, 1901, 1907, 1908, 1909, 1912, 1914, 1915, 1919, 1920, 1921.

1848. C. L. LIGHT. *Improvements in electric telegraph ropes or cables.* Dated August 13, 1858.

This invention was described and illustrated at page 141, No. 9, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1849. T. RICKETT. *Improvements in locomotive engines and other carriages to facilitate their transit.* Dated August 13, 1858.

This consists in giving to the engines through an elastic medium a more extended bearing surface. In place of each driving wheel, the patentee employs two or more small wheels, placed equidistant longitudinally from the central axis; and around these wheels he places an elastic hoop or hoops of proportionally large diameter, made of a thin plate or plates of steel, &c. Within this hoop the wheels roll, and the weight of the engine coming upon these hoops at two or more points beyond the centre of bearing, the hoop yields to the weight till the bearing points of the wheels approach or touch the ground, so that that portion of the hoop between the bearing points becomes nearly flat, and the load is sustained by a portion of ground approaching to the whole distance between the centres of the roller. *Patent completed.*

1850. J. PETRIE, jun. *Improvements in machinery or apparatus for stretching and drying woven fabrics.* Dated August 13, 1858.

This relates to a former patent, dated 30th June, 1858. The patentee causes a band or bands armed with hooks or teeth to travel over the rollers with the cloth, which bands are guided in their motion, and are drawn outward by weights, &c. *Patent completed.*

1851. T. WORTH and H. SPENCER. *Improvements in machinery or apparatus for preparing for spinning, and for spinning cotton and other fibrous materials, and in winding and warping yarns of the said materials, and in making wire cards for such preparing machinery.* Dated August 13, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1852. G. SCHAUB. *New or improved machinery to be used in the manufacture of certain kinds of printing types, and also in the manufacture of spaces and quadrats used in setting up printing types.* Dated August 13, 1858.

This relates to a previous patent granted to the inventor, dated the 16th of April, 1857. A circular table having a series of radial slots is mounted upon a vertical axis, and capable of motion in a horizontal plane. In the radial slots beds are placed, the said beds being impressed with the types to be manufactured. The heads of the types, made of copper, and coated at back with soft solder, are cut from the sheets in which they are made by a fly press, the lower die used in the press having a spring bottom by which the type head cut out is raised from the die. The separate type heads are placed in the beds on the table, the backs of the type heads being uppermost. The bodies of the types are cast on the heads by a mould, one-half of which is fixed over the table in the direction of a radius, and the other half of the mould is moveable. The table is turned until the bed filled with type heads is brought under the fixed part of the mould. The moveable half of the mould is connected to the fixed half, and the bed is made to bear up against the under side of the mould, and is fixed accurately in its place. The said bed constitutes the bottom of the mould. Fused type-metal being poured into the mould, the metal attaches itself to the type heads, and forms bodies thereto. The mould is opened and the types removed. The bed is depressed so that it can pass freely under the fixed part of the mould, and another filled bed be brought under it. *Patent abandoned.*

1853. J. H. JOHNSON. *Improvements in the treatment of crude india-rubber, gutta percha, or other vulcanized gums, and in the manufacture therefrom of what are usually called hard rubber articles.* (A communication.) Dated August 13, 1858.

This consists, 1, in passing the crude gum in masses of from 10 to 30 lbs. weight through toothed rollers having a slipping motion; 2, in the use of alternative pressure and vacuum in cleansing raw gums; 3, in grinding together about two parts by weight of the gum with one part of sulphur, preparatory to running the heat; 4, in running the heat from about 275° Fahr. at the commencement of the process to about 300°; 5, in certain means of equalising the temperature in the heating apparatus. *Patent completed.*

1854. T. G. PENDELLY and H. BROWN. *Improvements in apparatus for straightening gun barrels.* Dated August 13, 1858.

The inventors straighten gun barrels without defacing the outside of the barrel, or striking or bruising the inside of the same. *Patent abandoned.*

1855. J. CARTMEL. *Improvements in the manufacture of hats, caps, and other coverings for the head.* Dated August 14, 1858.

This consists in making the foundation or body and brim of a hat of a linen or cloth prepared with caoutchouc. The cloth is lined with a piece of linen, and the latter is caused to adhere to the former by using shellac, powdered and dissolved in water impregnated with ammonia, with any of the resinous gums possessing sufficient property of adhesion. *Patent completed.*

1856. M. A. F. MENNONS. *Improvements in the construction of Jacquard looms.* (A communication.) Dated August 14, 1858.

A complete specification of this invention was filed with the application. It consists in a construction of Jaquard looms, specially applicable to carpet manufacturers, and in certain cases to the production of shawl and "brochè" tissues. *Patent completed.*

1857. J. HOLT. *Improvements in looms.* Dated August 14, 1858.

This relates to mechanism for operating rotary shuttle boxes for producing the various changes of shuttles required in fancy weaving, and consists in constructing apparatus capable of being governed by a small Jaquard machine affixed to the loom end, and receiving motion therefrom. *Patent completed.*

1858. J. SMITH and S. A. CHASE. *Improved arrangements for obtaining and applying motive power.* Dated August 14, 1858.

This consists of certain complicated mechanical appli-

Digitized by Google

ances "so arranged as to co-operate with the motive power of the atmosphere." *Patent completed.*

1859. A. SLATE. *Improvements in blast furnaces and in smelting iron ore.* Dated August 14, 1858.

This invention was described and illustrated at page 205, No. 13, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

1860. S. C. LISTER and J. WARBURTON. *Improvements in dyeing wool, hair, cotton, flax, and similar materials, also yarns and textile fabrics made from such materials, also in dyeing and tanning other substances and materials, also in washing wool, and in discharging the gum from silk.* Dated Aug. 14, 1858.

These consist in dyeing in vacuum. The material is placed in an air-tight vessel, through a door, which is then closed, and the air exhausted. The colouring matter is then admitted. *Patent completed.*

1861. C. O'NEILL. *Improvements in the manufacture of artificial gums from starch, farina, and other amylaceous substances, and in apparatus for such manufacture.* Dated Aug. 14, 1858.

This consists, 1, in subjecting starch, farina, &c., to the chemical action of muriatic gas or other acid gas or vapour, the substances acted upon being heated to a proper temperature either before or after the admission to them of the gas or vapour employed. 2. In the following apparatus for effecting the aforesaid purposes:—starch, farina, &c., is inclosed within a cylindrical chamber, into which the gas or vapour is admitted, and which is surrounded by another chamber heated by steam. The starch, farina, &c., is stirred about by revolving arms within the inner chamber. *Patent completed.*

1862. G., G. W. and J. BETJEMANN. *An improvement in book-slides.* Dated Aug. 14, 1858.

This consists in fitting vulcanized caoutchouc springs to the slides so that the side supports shall always return to the position from whence they have been drawn upon the extra book or books being taken from the slide. *Patent abandoned.*

1863. W. E. NEWTON. *An improved combination of metal with india-rubber or gutta percha, or with india-rubber or gutta percha combined with other substances, in the manufacture of belting, hose, valves, and other articles.* (A communication.) Dated August 14, 1858.

This consists in the combination of wire cloth or wire netting with india-rubber or gutta percha in the manufacture of the above-named articles. *Patent abandoned.*

1864. L. A. FOROT. *A new mode of ornamenting fabrics, and in the apparatus connected therewith.* (A communication.) Dated August 14, 1858.

The object here is the manufacture of a new kind of fabric composed of threads of silk or other fine material, glued upon paper or any kind of materials, and in ornamenting the said fabric. This is done by a cylinder upon which the material is fixed. One or several bobbins, or a comb containing a certain number of threads, are supported above the cylinder by a screw or otherwise. The paper or material placed upon the cylinder is glued by a sponge or otherwise, and the cylinder in turning communicates the movement to the screw, which distributes the silk or other material, so that it will be glued spirally upon the cover of the cylinder, and when the operation is finished the fabric is separated from the cylinder by a knife. *Patent completed.*

1865. G. K. GETFLIN. *Folding bedsteads, and which he calls the universal and folding joint for bedsteads.* Dated August 16, 1858.

To the bedstead posts the inventor fixes a plate with one or more holes which serve as centres from either of which the head and foot rails may be folded on the frame. Through these centre holes set screws or bolts are screwed into the frame, by which a bedstead can either be folded or taken to pieces like an ordinary bedstead. *Patent abandoned.*

1866. P. E. CHAPPUIS. *Improvements in stereoscopes and stereoscopic apparatus.* Dated August 16, 1858.

This comprises the construction and arrangement of stereoscopes, 1, folding in the form of a book. 2, in the form of an oblong box, resembling a colour box with a sliding lid. *Patent completed.*

1867. C. G. CUTCHEY. *A railway danger signal whistle.* Dated August 16, 1858.

Here upon a rod being liberated, certain catches are raised, and upon an engine passing the catch, a lever, which projects some inches below, strikes against one of them, and which lever moving on a pivot or moveable joint is thrown out of a notch or groove in the handle of the whistle, which being acted upon by a spring opens the cock, thereby letting the steam into and blowing the whistle. *Patent abandoned.*

1868. L. A. and E. I. E. HERMANN. *Improvements in connecting together pipes, tubes, or ways, for the conveyance of water or other fluid, and in the means or apparatus for regulating the flow, or discharge and supply of such fluid, and in means or apparatus for facilitating the forming of such connections.* Dated August 16, 1858.

One object here is to facilitate the connecting together of lengths of pipe, without employing hot metal, or of soldering; and also the use of piping without flanges. The patentees apply over the adjoining ends of the pipe a band or ring of lead, and force such into close contact by two compressing rings of iron formed conical on the inside, to press tightly upon the ring or band of lead *Patent completed.*

1869. A. V. NEWTON. *Certain improvements in machinery for forging horse-shoes.* (A communication.) Dated August 16, 1858.

This consists in certain methods of operating mandrills, die rollers, and punches, for forming horseshoes from bar iron, producing the creases in the same, and punching the holes therein. Also in improved application of discharging apparatus for delivering the shoes from the machine as fast as they are completed. *Patent completed.*

1870. P. RICHARD. *Improvements in apparatus for obtaining motive power.* Dated August 16, 1858.

This consists in communicating a rotary motion to a fly-wheel or drum, by a set of falling weights tied together by chains, ropes, or straps. *Patent abandoned.*

1871. J. WEBSTER. *A new or improved projectile.* Dated Aug. 17, 1858.

This consists of a projectile having an external figure resembling that of the Minié bullet, and having a hole in its axis, which hole is rifled, or has a series of helical grooves or planes formed therein. The effect of the rifled hole is to give the projectile a rotary motion as it progresses through the air. *Patent abandoned.*

1872. W. E. EVANS. *Improvements in harmoniums, concertinas, organs, and other similar keyed instruments.* Dated Aug. 17, 1858.

This invention has reference to eliciting immediate tone from what are called the free reeds of harmoniums and similar-keyed instruments, on touching the keys or pedals of the same by mechanism attached to the keys or pedals, and actuated solely by the hand or foot of the performer. The invention is not described in detail apart from the drawings. *Patent completed.*

1873. J. JACKSON and A. FISHER. *An improvement in the manufacture of hats.* Dated Aug. 17, 1858.

This consists in substituting thin sheet steel or copper, in lieu of the materials at present in use for the bodies of hats and shakoes. *Patent abandoned.*

1874. G. HALKERSTON. *Improvements in mangles.* Dated Aug. 17, 1858.

This consists of a pair of vertical parallel standards of cast iron, held together transversely by horizontal tie rods, so as to abut at their ends, and a pair of wood rollers of large diameter, the upper one of which has attached to it the ordinary taking-in cloth. The end journals of the lower roller on which the pressure comes rest in upon a pair of antifriction disc wheels, the stud spindles of which run in bearings carried by an adjustable block or saddle-piece let into an opening in the standard. The end journals of the upper roller run in vertically adjustable bearings, fitted into slots in the main standards above, the pressure upon the pair of rollers being regulated by a compound plate spring. *Patent abandoned.*

1875. J. NORTON. *Improvements in projectiles.* Dated Aug. 17, 1858.

This invention was described and illustrated at, page 250, No. 1831, of the MECHANICS' MAGAZINE. (Old Series.) *Patent completed.*

1876. F. SHAW. *Improvements in spindles for the spinning of silk and other fibrous material.* Dated Aug. 17, 1858.

This relates to hollow brass spindles, and consists in working them upon a steel stud, having a steel cap at top of about one inch and a quarter in length, to protect the part from abrasion, the brass or metal passing through the steel cap and thus forming a bush, whereby the patentee can drive the spindles at a high speed. The bottom of the spindle is secured by a thumb-screw. The spindles are each only about seven inches in length. *Patent completed.*

1877. G. MILLS. *Improvements in machinery for cutting wood for staves.* Dated Aug. 17, 1858.

The wood is moved to the saw by a cylindrical drum, and a flexible band which is fixed at one end to the circumference of the drum, and at the other end presses against the end of the piece of wood, so as to move it as the flexible band is wound on to the circumference of the drum. The piece of wood is, whilst being moved up to the saw, held between two wheels or rollers, one acting as a pressing roller to press the wood against the periphery of the other. The wheel or roller against which the wood is pressed is of the same diameter as the wheel on which the flexible band is wound, and they are both formed with cog-wheels, and are driven at a like surface speed by a pinion. By these means straight sawing will be accomplished, but to cut the staves thicker at the ends, provision is made to incline the wood to the saw at the two ends, to cause the saw to cut in an inclined direction; and there are recesses in the wheel against which the wood is pressed, into which the ends of the piece of wood enter, and these recesses are varied in position to suit different lengths of wood. *Patent abandoned.*

1878. D. LICHTENSTADT and C. DUFF. *Improvements in treating tan and tanning refuse to obtain valuable products therefrom.* (A communication.) Dated Aug. 17, 1858.

The object here is to bring into use the refuse material of tan oak bark, its properties having been exhausted, and which, after passing through a certain process, is converted into, 1, charcoal, for the manufacture of gunpowder; 2, charcoal for filtering purposes. After such process there remains, 1, liquecous acid for different chemical and technical purposes; 2, wood tar; 3, the hydro-carbonic gas, which is used in the distillery processes by burning under the apparatus, which greatly reduces the expenditure of fuel. *Patent abandoned.*

1879. J. LUIS. *A new safety system for preventing an accidental discharge in fire-arms.* (A communication.) Dated Aug. 18, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1880. A. V. PINTA. *Improvements in blank forms of cheques, or drafts on bankers, payable on demand, relating to the crossing of such cheques or drafts.* Dated Aug. 18, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE (Old Series). *Patent completed.*

1881. W. SOELMAN. *Additional improvements in the construction of propellers, chiefly with reference to his former patent.* Dated Aug. 18, 1858.

This relates to a former patent, and consists of certain modifications in the form of the floats. It is not described apart from the drawings. *Patent abandoned.*

1882. T. WILLIAMS. *An apparatus to be used for a churn or for a washing-machine.* Dated Aug. 18, 1858.

This consists of a cylindrical or conical vessel, with a vertical shaft, mounted in bearings and fitted with open framework beaters or stirrers, to which a lateral alternating or rotary movement is given by a link motion attached horizontally to the said spindle, which is driven direct from a crank action through the medium of a connecting rod and fly-wheel. *Patent abandoned.*

1883. R. ANDERSON. *Improvements in stuffing-boxes and packings.* Dated August 18, 1858.

This relates, principally, to piston-valve and pump-rod stuffing-boxes; and consists of a quadruple or other set of brass segments, made to fit accurately to the rod by being unbraced by two external plate-springs. *Patent completed.*

1884. T. O. DUKE. *Improvements in preparing cheques and such like documents, and in the means of preventing forgery or surreptitious alterations.* Dated August 18, 1858.

The inventor punches out from documents pieces according to any design, and as these openings cannot be filled up without detection, it prevents tampering with crossed cheques, drafts, &c. *Patent abandoned.*

1885. A. PILBEAM. *A bradawl screw.* Dated August 19, 1858.

The patentee describes a screw terminating with an end similar to the bradawl in use. It merely requires to be struck with the hammer down to the end of the bradawl part and commencement of the screw; the screw driver must then be applied to turn it, and it will be found to penetrate the wood as quickly, if not quicker, than the ordinary screw, which requires a hole to be made for it. *Patent completed.*

1886. W. HUDSON and C. CATLOW. *Certain improvements in looms for weaving.* Dated Aug. 19, 1858.

This consists, 1, in regulating the delivery of the warp from the warp beam, in which the warp as it passes from the warp beam to the healds is caused to pass under a moveable rod, shaft, or roller, connected to the weight levers. 2, In regulating and controlling the delivery of warp from the warp beam, in which the said warp is caused to pass under a moveable rod, roller, or shaft, which falls or rises as the weaving proceeds according as the quantity of warp delivered is in excess or deficiency. 3, In the use of a stop, latch, detent, &c., to retain the stop rod in its working position, and to prevent it from recoiling. 4, In the use of a pair of buffers (one upon each spindle) to absorb the momentum of the pickers, and to prevent the collision thereof with the spindle studs. 5, In an apparatus for preventing floats. *Patent abandoned.*

1887. W. F. PADWICK. *A machine or implement to be employed on and sown with turnips to protect them from the ravages of the fly, applicable also to the protection of other crops.* Dated Aug. 19, 1858.

Upon a suitable frame and mounted upon wheels the patentee places a vessel for holding water or other liquid. This liquid vessel has a pipe extending across the implement fitted with cocks in various parts, some of which are opened to come over the rows of plants. Under the taps is a wire-gauze or rose-spreader for depositing the liquid in a fine shower upon the plants. A hopper extending across the implement is supported upon the frame behind the liquid vessel. This hopper contains the dry material to be applied over the moistened plants. The hopper has a shaft with arms rocking in it for delivering the contents into as many shoots provided with adjustable parts as there are rows of plants between the wheels of the implement. From the shoots the material falls into sieves which have a jogging motion imparted to them, and which distribute the dust, grit, &c., over the plants. *Patent completed.*

1888. J. C. PLOMLEY. *Improvements in joists and laths used for supporting hair and other pervious floors in oast houses.* Dated Aug. 19, 1858.

This consists in making the joists and laths taper off towards the top on which the floor rests, whereby much less of the floor will be covered, and consequently an extended floor surface will be exposed to the rising currents of heated air and other drying and evaporating agents. *Patent abandoned.*

1889. M. F. J. DELFOSSE. *Improvements in electro-magnetic machines.* Dated Aug. 19, 1858.

This relates to that class of electro-magnetic machines in which powerful induced currents are obtained by the revolution of wheels or discs carrying covers of soft iron surrounded with coils of wire and made to revolve between the poles of fixed permanent magnets; the induced currents are collected from the whole series of coils, and conveyed by metal conductors to be used as required. This invention consists in the apportioning of the number of coils composing each disc or wheel to the magnets between which they pass; in arrangements of the conducting rings in order to avoid the electric spark; in the employment under certain circumstances of uninterrupted or unsplit annular rings; in means of coupling the coils according to the intensity or quantity of the current desired to be obtained; in the arrangements of the coupling of the coils with the split or full rings for those applications where the electric currents are required to be fixed or changeable, of weak or strong intensity; and in the employment of split coils for the purpose of increasing the energy of the currents. *Patent abandoned.*

1890. W. SMITH. *Improvements in steam engines.* (A communication.) Dated Aug. 19, 1858.

Here two cylinders are placed each at an angle of about 25 or 30 deg., their connections converging to the crank, axle, or shaft, the air pump and condenser being disposed between the two cylinders, and immediately under the crank shaft, and the cold water, injection, feed, and bilge pumps are disposed alongside the air pump, working vertically or horizontally, the starting and reversing gear being worked by a wheel acting by means of connecting rods upon the links and eccentric and slide gear of the two cylinders. The exhaust pipes branch out from either side of the condenser to the lower side of the steam chest of each cylinder, whilst each cylinder has upon the upper side or face of the steam chest a pipe branching from the boiler. High pressure steam is used, which, after having performed its work in propelling the piston in one direction, is caused to pass through a double or hollow slide valve, by which the steam at the end of the stroke has free access to the opposite

Digitized by Google

end and greater area of the piston, where it expands and propels the piston back, or performs the up-stroke, which having been done, the steam which has been expanded and performed its work as described escapes into the condenser. *Patent completed.*

1891. W. PEARCE. *Improvements in the manufacture of air-tight bottles, jars, or similar articles.* Dated August 20, 1858.

The patentee claims making bottles, jars, &c., with projecting studs or lugs on the necks thereof, such studs or lugs entering into grooves, and so forming air-tight coverings thereto. *Patent completed.*

1892. W. A. MUNN. *An improved method of constructing railway carriages, whereby greater safety is insured in case of collision.* Dated August 20, 1858.

Here the body of the carriage is built separately from the platform or bed on which it rests in grooves, in such a manner as to be capable, when a considerable force is applied, to slide along either end of the platform or bed. *Patent abandoned.*

1893. F. PRESTON and W. MC GREGOR. *Improvements in machinery for cutting files.* Dated August 20, 1858.

This consists, 1, in a mode of constructing the socket and joint of the chisel-holder in combination with a spring applied to the tail of the chisel-holder. 2, in holding the chisel rigidly between the jaws of a vice or clamp forming the chisel-holder, the chisel being held in its place in the vice or clamp by a pin, key, or a cottar. 3, in so constructing the cam for working the screw by which the table is moved, that after the table has been moved the necessary distance for cutting a fresh tooth, the action of the cam imparts a slight forward pressure on the table until the blow of the hammer has been given. 4, in the application of a friction clip or brake to the screw by which the table is moved. 5, in the application of a loose weight or weights to the top of the hammer. 6, in supporting the chisel-holder in a slide, in order that the chisel may be raised off the file in a line parallel to the cut. *Patent completed.*

1894. H HOOD. *Improvements in the manufacture of railway tyre bars, boiler plates, bar iron, and forgings.* Dated August 20, 1858.

This consists in the application of Swedish and Russian pig-iron in the manufacture of railway tyre bars. Also in the manufacture of railway tyre bars, boiler plates, bar iron, and forgings from Swedish and Russian pig-iron combined with the pig-iron manufactured in England, Scotland, and Ireland. *Patent abandoned.*

1895. L. F. H. DROINET. *Improvements in bearings and packings for rotating and reciprocating shafts, the joints of pipes, and other like purposes.* Dated August 20, 1858.

These bearings and packings are composed of three or more segmental blocks, which when brought together form a circular hole on the inside for the reception of the shaft or pipe; each segment is pressed inwards by a spring or springs. *Patent abandoned.*

1896. P. SPENCE. *Improvements in the manufacture of alum.* Dated August 20, 1858.

This consists in a method of obtaining small crystals or powder of alum, and consists in accomplishing this object by the adaptation to the pans which contain the solution of mechanism, which by a rotatory or reciprocating action keeps the fluid in agitation. *Patent completed.*

1897. J. L. FIGGETT. *An improved construction of syringe or hand pump.* Dated August 20, 1858.

The patentee claims constructing syringes or hand-pumps, whereby with the exercise of one hand alternately pressing upon and releasing the pressure from the barrel, the operator is enabled to throw a continuous stream: thus leaving the other hand free for directing the stream, or for other use. *Patent completed.*

1898. W. CLAY and E. L. BENZON. *Improvements in the manufacture of iron and steel.* Dated August 20, 1858.

In carrying out this invention in a puddling furnace of the ordinary construction, a charge of pig iron, or refined iron, or plate metal, is introduced into the furnace in the usual manner, together with an equal quantity of hammer slag or cinder, or other vitreous material, and when these ingredients are melted together they are worked in a similar manner to that usually adopted in puddling iron, taking care to melt and boil the iron at as great a heat as possible. The iron, after boiling for a considerable time, commences to thicken, and grains of steel begin to appear on the puddling tool, or to rise through the covering layer of cinder, or vitreous material. The damper must then be shut down, and as soon as the ebullition subsides, the metal must be gathered together and balled up quickly, taking care to keep the mass as compact as possible, and protected from the influence of the atmosphere. The ball when withdrawn from the furnace may be hammered, squeezed, and rolled in the usual manner. *Patent completed.*

1899. T. KNOWLES. *Improvements in looms for weaving.* (A communication.) Dated August 20, 1858.

This relates to arrangements of the parts constituting several motions of the loom; the strap pulley is mounted upon a shaft capable of actuating a second or main shaft by gear. Upon this second shaft is a stud, which, when the loom is driven, is held by a catch mounted on the wheel, which is driven by the pulley and brought into action by the stop rod. The lathe vibrates by a cam acting against a lever, which lever causes a bell crank to turn upon its centre, and communicates motion to the lathe by a connecting rod. The lever is kept in contact with the cam, and the lathe brought back by a spring. In the picking motion a lever is forced backward against the spring, and carries with it the picking stick; in this situation it is confined by a catch, which is liberated when the pick is required, and the force of the spring projects the shuttle. To the lever an arm is connected which causes the picker to occupy its proper starting position. To the warp beam is applied a metal band as a brake. This band is held by levers which are regulated in position by a roller placed in contact with the warp. *Patent abandoned.*

1900. A. BAKER. *An improved method of, and apparatus for submerging or laying under water electric cables, wires, or lines, and for the recovery thereof.* Dated Aug. 20, 1858.

The inventor claims a kink indicator apparatus, and certain self-inflating buoyant and retarding floats. Also, self-attaching and self-detaching nippers, whether used the latter in connection with the floats or otherwise, and whether constructed principally of wood or metal, or a combination of both. The invention is not described apart from the drawings. *Patent abandoned.*

1901. F. F. DELPY. *Improvement or improvements in metallic stay-busks.* Dated Aug. 21, 1858.

The patentee makes the busks without the rivetted studs, or gives them a different disposition. The blades are punched out from steel sheets. *Patent completed.*

1902. G. J. WALKER. *Improvements in funeral carriages.* Dated Aug. 21, 1858.

This consists in fitting mourning-coaches with arrangements for carrying the coffin upon the roof thereof; for which object a sarcophagus-shaped top is employed in connection with a shifting scroll iron step, together with fixed and moveable rollers for raising or lowering the coffin. *Patent abandoned.*

1903. M. BENSON. *Improved apparatus for generating steam.* (A communication.) Dated Aug. 21, 1858.

This relates to apparatus for generating steam with great rapidity and economy, and with perfect safety. The centre or flue space of the boiler (which is jacketed) is divided into compartments by vertical partitions, and in each of the compartments a system of serpentine pipes is fixed, their lower ends in communication with a pump, and their upper ends communicating with the steam space of the boiler. The flame and heated gases from the fire-place play upon and around the pipes. A circulation of water is kept up through the pipes by a pump. A second pump is used for supplying water to the jacket of the boiler. *Patent completed.*

1904. R. A. BROOMAN. *Improvements in sewing machines.* (A communication.) Dated Aug. 21, 1858.

These relate to the feed of material to be sewn in a sewing machine, and consist in a means of causing the cloth to progress by a mechanism acting so as to grasp the cloth between two surfaces, and give the feed without the aid of spring pressure. *Patent abandoned.*

1905. W. HENSON. *Improvements in circular looms or knitting frames.* Dated Aug. 21, 1858.

This consists in arranging such machines so that the fabric produced upon them may be increased or diminished in width by the automatic action of the machine. *Patent completed.*

1906. C. DE JONGH. *Improvements in machinery for combing and heckling fibrous materials.* Dated August 21, 1858.

This relates to a machine patented 29th October, 1856. In this machine the fibres were fed up to rotary combs between endless chains, which were pressed into contact with the fibres by pressing rollers, and thereby caused to hold the fibres fast while under the heckling or combing action. The patentee now proposes to construct them of flat blocks of wood or plates of iron, with square abutting ends, and to connect them together by securing them to an endless band of vulcanised india-rubber, &c. *Patent completed.*

1907. R. LAMING. *Improvements in purifying gases and liquids, in preparing and purifying liquids, and in apparatus for apportioning or measuring liquids.* Dated Aug. 21, 1858.

This consists, 1, in removing sulphuretted hydrogen from foul gases by the catalyptic use of certain metals in combination with oxygen, as, for example, the precipitated sesquioxide or peroxide of manganese. 2, in removing sulphuretted hydrogen from gas, liquor, or other foul liquids, by the use of the re-agents above indicated. 3, in a "tumbling box" or fluid measurer controlled by a weight spontaneously shifting, as required, from one part of the apparatus to another. *Patent abandoned.*

1908. W. W. HARRISON. *An improvement in cruet and liqueur stands.* Dated August 21, 1858.

This consists principally in forming such stands with an open frame of silver or other metal, and filling in such frame with sides or panels of glass, porcelain, &c. *Patent abandoned.*

1909. F. PULS. *Improvements in the distillation of coal.* Dated August 21, 1858.

This consists of a mode of distilling coal with the addition of earthy, alkaline, or metallic oxides, peroxides, sesquioxides, or protoxides, or the carbonates or hydrates of those substances, for obtaining gaseous products and tar from the coal distilled. *Patent completed.*

1910. F. PULS. *Improvements in the distillation of bituminous matters and gas tar.* Dated August 21, 1858.

This consists in a mode of distilling such matters or gas tar with the addition of, or mixed with, earthy, alkaline, or metallic oxides, peroxides, sesquioxides, or protoxides, or the carbonates of hydrates of those substances, for preventing the adhesion of the residuum to the interior of the retort, and for obtaining fluid, solid, and gaseous hydrocarbons or products from such bituminous matters. *Patent completed.*

1911. M. R. PILON. *Improvements in the manufacture and construction of fire-arms, and in the means of loading the same.* Dated August 23, 1858.

The objects here are, 1, to control the recoil. 2, to secure the precision of the aim by altering the position of the trigger of small arms. 3, to load quickly by a metallic charge-bearer for the weapons that are charged through the breech. The breech is closed up with a cap or stopper having a spiral spring; this spring has a fulcrum at the back part on the carriage. When the gun is fired the recoil presses upon the spring, and by thus pressing it the cap which stops the breech is maintained at its place. The carriage of the cannon has cog-wheels or springs, on which the trunnions press. *Patent completed.*

1912. C. BUONO-CORE. *A liquid or composition which when applied to substances of any kind will render them fire-proofs or uninflammables.* Dated August 23, 1858.

The object here is to render fire-proof every substance or material, and the inventor effects this with the following composition:—A solution of alum, 20 parts; extract of archicouta, 30 parts; fluoric acid, 50 parts; a solution of glass, 100 parts. The coating is made by a brush, and it is placed upon the furniture instead of the ordinary varnish. *Patent abandoned.*

1913. L. HIGGINS AND A. BROWN. *Improvements in reefing the sails of navigable vessels,* Dated August 23, 1858.

The patentees employ a combination of parts, to effect the rolling up of the topsails upon revolving yards. *Patent completed.*

1914. A BOYLE. *Improvements in the manufacture of certain parts of umbrellas and parasols, and in machinery employed in the said manufacture.* Dated August 23, 1858.

This consists in making the runners from circular discs of sheet metal, by raising tools; also in a machine for effecting the flattening, and also for making the knob at the ends of umbrella and parasol ribs. *Patent completed.*

1915. T. AVERILL. *An improvement or improvements in mills for grinding.* Dated August 23, 1858.

The patentee claims, 1, making a grinding mill of a series of nearly flat plates of sufficiently hard metal or alloy, the surfaces of the said plates being corrugated or grooved, some of the said plates being stationary, and others of the said plates moveable, the said moveable plates alternating with the stationary ones; the said moveable plates being actuated by a crank 2, making the upper edges of the plates thinner than the lower edges in those parts constituting the bottoms of the grooves, the thickness of the said plates gradually increasing from the top to the bottom; or making the grooves or depressions between the ribs on the said plates shallow at the bottom, and gradually deeper as the said grooves or depressions approach the tops of the plates. 3, notching the plates on their upper edges, to facilitate the breaking and feeding of the substance to be ground. *Patent completed.*

1916. H. D. JENCKEN. *Improvements in electric telegraphs.* (Partly a communication.) Dated Aug. 23, 1858.

This consists in the use of the earth itself as a conductor of galvanic, magnetic, electro-magnetic, and electric fluids of all kinds, without any conducting wire or wires. In the use of substances in a dry or wet state under ground for producing an electric current at the transmitting and receiving points and stations. In insulating and preventing by non-conducting substances any lateral action from interfering with the direct communications from point to point. In changing the characters of the electric fluids, to prevent the interfering action electric currents would be liable to in their course from one point to another. *Patent abandoned.*

1917. J. H. ROBINSON. *An improved shirt.* Dated Aug. 23, 1858.

This relates to a shirt which may be worn as a shirt and waistcoat, or simply as a shirt. Marsala or other waistcoat stuff is sewn to the front of the shirt extending from the neck to the waist, and allowed to hang loose to the length of an ordinary waistcoat. The waistcoat stuff is carried from the neck to the shoulder on each side, and down each side-seam of the shirt as far as the waist; or the fore part of the shirt may be formed entirely of waistcoat stuff, and the fore part of the shirt attached to the waistcoat stuff inside. *Patent abandoned.*

1918. W. H. HARFIELD. *Improvements in windlasses.* Dated Aug. 23, 1858.

Here, in order to give motion to a windlass barrel, two cog or toothed wheels on parallel axes are used, which gear into each other, and one of them also gears into a wheel on the axis of the windlass barrel. On the axis of one of the two cog-wheels there is a lever which is caused to vibrate by windlass bars, and by connecting rods motion is communicated from the above-mentioned lever to a second lever which moves on the axis of the other cog-wheel. Each lever carries a driver or drivers arranged to give motion to its cog-wheel, and so that the two cog-wheels are driven alternately by their respective levers and drivers. That a windlass may be more conveniently arranged to deliver a cable, there is a brake-wheel fixed on the axis of one of the cog-wheels, to which there is applied a brake-strap and lever. *Patent completed.*

1919. A. ROTTMAN. *Improvements in fastenings for bags, porte-monnaies, pocket-books, and similar articles.* (A communication.) Dated Aug. 23, 1858.

The patentee bends a piece of steel wire into a staple or loop or V-form, passes the ends of the branches through a slit or slits in one of the jaws of the bag, and attaches knobs to them. The angle or bond of the staple may be secured by a screw. By pressing the two knobs towards each other this spring staple is compressed, and can enter a recess or recesses in the other jaw, and then being allowed to expand again it enters notches at each end of the recess, and thus secures the two jaws together. The edges or ends of the recess are bevelled to allow the spring staple to enter the recess by merely pressing the jaws together. *Patent completed.*

1920. C. A. SCHRADER. *An instrument to be used in boring, for mining or other purposes.* Dated Aug. 23, 1858.

This consists of a metallic bar or stem, with a point or head of steel, furnished with three chisel-pointed cutters, so arranged as to admit of the instrument turning on the centre one, the point of which is formed to extend below the others for that purpose, so that by a downward force and rotary movement being communicated to the said instrument, the operation of boring may be effected with little labour and great precision. *Patent abandoned.*

1921. H. B. BARLOW. *Improvements in self-acting lubricators.* (A communication.) Dated Aug. 23, 1858.

This consists, 1, in apparatus for lubricating, whereby a uniform supply of oil or other lubricating material is delivered at intervals to the axle; 2, in marking divisions on the glass, oil-cup, &c., for indicating the consumption of the lubricating material; 3, in a mode of constructing lubricators with endless chains or bands, by which the oil, &c., is raised from the oil-cup and delivered to the axle; 4, in supplying oil, &c., to the axle by a roller (around which a strip of felt or other elastic substance is wound in the form of a thread or spiral), floating in the oil, &c. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, APRIL 15, 1859.

THE SHIPS OF THE NAVY.

We have received with pleasure the mass of information on the navy lately presented to the House of Commons, and have published that portion of it with which the bulk of our readers are likely to concern themselves. Into the great question of naval expenditure we have never up to the present time entered, nor do we propose to enter upon it now. Our business has hitherto been, and still is, with the ships of the navy, and with them only.

Our present purpose is simply to draw attention to the manner in which Lord Clarence Paget's statements with reference to the alterations of ships have been disposed of by the Surveyor of the Navy. And that this matter may be made perfectly plain to the public we have placed the rejoinders of the Surveyor by the side of Lord Paget's assertions—adding our own in a third column, in order to verify their accuracy. The result of the whole affair is, that Lord Paget is left without the least basis of truth for his allegations. Nor is this all. Sir Baldwin Walker takes occasion in his explanations to remind the Admiralty and the public that a sum less than £400 is "the only sum expended on all the screw-ships designed within the last eleven years, which might have been saved if the views subsequently carried into effect had been adopted in the first instance." This is a fact which not only Lord Paget, but the Admiralty themselves would do well to bear in mind; for such is the present efficiency of the "construction" branch of the Surveyor of the Navy's department, that neither Lord Paget, nor Sir John Pakington, nor Mr. Corry can interfere in its operations without disadvantage to the service; and all of them seem disposed to do so, if we may judge by their speeches in Parliament. Not a word of truth has been adduced in proof of any serious inefficiency in our ships of war. The constructors of the navy are at the head of their profession, and unprofessional persons cannot therefore give satisfaction by interfering with their business. To the criticism and interference of competent persons no sensible person would object; but when men without the most elementary knowledge of ship-construction are so indecorous as to interpose in such a matter, it is high time to protest against their presumption.

SIR J. PAKINGTON *versus* SIR C. WOOD

We do not know what the temper of the House of Commons was last Wednesday afternoon, during the war waged between the present and the late First Lords of the Admiralty, but the report of the wordy strife has given us considerable amusement. Take this little dialogue:—

First Lord—I come now to the year 1858, when I succeeded to office. What had the right hon. gentleman done then? I understood him to say that eight line-of-battle ships were launched in 1858.

Ex-First Lord—What I said was, that eight line-of-battle ships were added to the navy in 1858, as appears by a return which I hold in my hand.

First Lord—I hold in my hand a return from which it appears that, instead of eight, the number is only four.

Ex-First Lord—Here is a return signed by Sir Baldwin Walker, Surveyor of the Navy, showing that of steam-vessels added to the navy in 1858 there were eight ships-of-the-line, viz., four built and four converted. That is the statement contained in paper 65 of the present session, for which I moved on the 16th of February.

First Lord—Well, I hold in my hand a printed return showing that there were only four added, viz., the Donegal, the Windsor Castle, the Hero, and the Edgar. I can only reconcile the difference by assuming that there were four built and four converted.

And so two honourable gentlemen bother each other, and mystify the House, because it is a State necessity that farmers, and lawyers, and county magistrates—any one, in fact, but a seaman—should manage the British Navy. It is to us a most surprising thing that the nation should ever have tolerated such an anomaly. Observe in the progress of this remarkable debate how the system works. Sir John Pakington had said on a previous occasion, that when he succeeded to office he did not find the navy of this country in a proper state, or adequate for the defence of our coasts and the protection of our commerce. Sir Charles takes this opportunity of defending himself, and does so with his usual adroitness and success. He considers that the accusation against him resolves itself into three heads:—that the late Board had neglected to ascertain the state of the French navy; that they did not build an adequate number of ships-of-the-line; and that they left the coasts of this country unprotected, so far as its safety depended upon the existence of an efficient naval force. Sir Charles said, with reference to the first of these points, that in May, 1857, he went at considerable length into a comparison between the existing states of our own and of the French Navy; that he adverted to the comparative strength of both at various periods of our history, and referred to the additional cost of a steam as compared with a sailing fleet. After stating that at the time he left office the French had twenty-two line-of-battle ships, and we had twenty-five, in addition to nine block ships, making a total of thirty-four vessels fit to take part in any action in the Channel, he quotes a portion of a speech made by Sir John Pakington, when defending his reduction in the estimates prepared by Sir Charles in respect of the outlay for the building of steam line-of-battle ships. On that occasion Sir John said—"The right hon. member for Halifax (Sir C. Wood) had complained that we had not line-of-battle ships enough, and that we had only two more than the French. That was true if only the line-of-battle ships actually afloat were meant, and the block ships were excluded. He admitted that those block ships should be superseded by line-of-battle ships as soon as possible; but four or five of those ships were in good condition, and it was not fair to exclude them." With reference to the next point—that they did not build an adequate number of ships-of-the-line—Sir Charles shows that he kept up such a supply of men in the dockyards after the close of the Russian war as to incur the condemnation of Sir James Graham. This he did because the labour which should have been employed in building large ships had been absorbed in fitting the transports and small vessels required by the exigencies of that war. Lord Clarence Paget said at that time in the House with reference to large ships—what we well remember was echoed loudly out of doors—"He was of opinion, therefore, that the First Lord might with great propriety rest upon his oars, and take the opportunity of consulting members of the naval service before he proceeded to add to the number of these vessels. Instead of increasing our line-of-battle ships he should appoint a committee to consider what description of vessels ought to be built." But Sir Charles thought this advice injudicious, and prepared the estimates for 1858—9, containing a very considerable increase in the building force of the dockyards, for the purpose of supplying the deficiency in large ships. The average number of men employed in building in 1856 was 1,600, but he proposed an addition of 1,340 men, or about 83 per cent. These estimates came into the hands of Sir John Pakington before they could be passed, and after having carefully considered them, he came to the conclusion that this increase in the establishment was not needed, and argued against Sir Charles upon our superiority over the French Navy.

After having the tables thus turned upon him by the statement of these facts, Sir John gets angry—adduces the arguments employed by Sir Charles Wood, in 1857, against the public feeling, and in favour of an increase in line-of-battle ships, to prove that the navy was in an inefficient state, and had been neglected—and actually condemns Sir Charles for adding *only* such a paltry sum as the £70,000 which he had himself struck out of the estimates as unnecessary! He says:—

"I leave it to the House to determine whether an addition of £70,000 to our naval estimates was sufficient to bring up our force to the position in which it ought to be, considering the state in which it was at that moment..... To come down to this House, as the Naval Minister, and propose an increase of only £70,000 to the estimates at a time when we had only 25 line-of-battle ships, I say was to fall greatly short of the duty which he owed to this country..... The right hon. gentleman complains that I cut down his estimates. But how much? Upon the matter of dockyard labour, I took off £20,000. I first proposed to take off £100,000. Sir Baldwin Walker remonstrated, and said he wished I would add £50,000. I did so. I then discovered the error about the £30,000 to which I adverted, and I added that sum; so that when I made my statement to the House in April the real difference between the right hon. gentleman's estimates and mine was only £20,000. But I would not have made that difference, or, indeed, any difference, if I had known then what I know now of the inefficient state in which the navy was left by the right hon. gentleman..... And now that we have come to a new session of Parliament, and have had to frame our own estimates, we have not, like the right hon. gentleman, made a proposal to take a vote of £70,000. Instead of this, we have proposed to take one for £1,300,000, which will enable us to add 26 powerful men-of-war to the navy, and to redress, so far as it is possible to redress, that positive and relative deficiency in our naval force which the late Government had allowed to exist." (Cheers.)

Not a bad day's work, Sir John! In order to squeeze out this money you had to show (if you could) that our navy was in a desperate condition when you came into office, and that your predecessors were grossly culpable; and this while you had yourself thrown away the means prepared by them for its improvement. And yet the House listens amiably, cheers, and votes the odd millions! You congratulate yourself, doubtless, on your lucky escape, and Sir Charles himself on the probability of having shortly to control the expenditure of the store which we, under the uncomfortable impression that we are being bamboozled by both of you, must work brain and hands to procure.

THE NATIONAL LIFE-BOAT INSTITUTION.

That sweet little cherub that sits up aloft and keeps watch for the life of poor Jack must witness with ineffable delight the proceedings of the National Life-Boat Institution. If his perch is sufficiently high for him to see the whole of our coast at once, and if, as we presume, he keeps his station all the year round, he must have had the gratification of be-

Digitized by Google

holding no less than four hundred and twenty-seven persons rescued in 1858 alone by its agency, and of seeing it distribute gold medals, silver medals, honorary distinctions, and pounds sterling in abundance to the gallant saviours of the shipwrecked men.

In order to deepen the interest that is felt in the proceedings of this invaluable Institution—which includes among its managers many eminent naval officers, and not a few of our own subscribers, we are glad to know—we will give a short summary of what it did last year in pursuit of its beneficent objects. In the first place it added 15 to the number of its life-boat establishments, of which it now possesses 81. It was also engaged in completing and re-organising the life-boat stations on the Norfolk coast, which have been transferred to its management and control by the merging of the Norfolk County Association into the Institution. The Tees Life-boat Society was also united with it, and its three life-boat establishments were re-organised and re-equipped. New life-boats were stationed in England at Cromer, Mundesley, Bacton, Winterton, Yarmouth (2 boats), Aberdovey, and Fleetwood; in Ireland—at Dundalk, Carnsore, Tramore, Dungarvan, and Newcastle, the last-named in lieu of a previous boat; and in Scotland—at Fraserburgh and Lossiemouth. New boats were also got ready to be sent to Exmouth and Kilmore. All these boats are on the self-righting principle, of which the committee continue to receive the most satisfactory reports. (We may mention incidently that one instance occurred of a single-banked self-righting boat having been upset by broaching-to when running before a heavy broken sea on her return from a wreck off Dungeness. Although this accident took place in the middle of the night, and at some distance from the land, yet the whole of the crew regained their boat after she had self-righted, which she immediately did, and not one of them was even hurt on the occasion—a striking proof of the value of the self-righting principle adopted by the Institution, and of the efficiency of the life-belts with which the crews of its boats are all provided, and which they are compelled to wear whenever they are on service). Anxious to make the valuable properties of the boats universally known, the Committee forwarded to the Governments of foreign maritime countries, and to the Colonial Governments of this Empire, lithographed drawings of the boats, and also of the transporting-carriages used with them, similar to those described on page 253 of this Number. The expense of these drawings was defrayed, at his own desire, by His Grace the Duke of Northumberland, the President of the Institution. The satisfactory result was that the builders to the Society were ordered to construct life-boats by the Governments of Russia, Prussia, and Portugal, and by some of our own Colonial Governments, the Committee being in every case requested to superintend their construction. Some of these boats have already arrived at their destination, and given much satisfaction. The life-boats of the Institution were instrumental in saving 110 lives during the past year. They also went off on 29 occasions to the assistance of vessels showing signals of distress, but the crews of which were eventually enabled to remain on board them, or were brought ashore by their own or other boats. Although some of these services were of the most arduous and dangerous character, they were performed without the loss of a single life. New life-boat carriages were built during the past year for Fraserburgh, Berwick, Boulmer, Alnmouth, Whitburn, Hornsea Cromer, Mundesley, Bacton, Winterton, Yarmouth, Camber, Bideford, Aberdovey, Groomsport, Newcastle, Carnsore, Tramore, Dungarvan, Ardmore, and Ballycotton. Further experience has suggested improvements in the construction of these important adjuncts to a life-boat, which the Committee have not failed to adopt. New boat-houses have been erected at Fraserburgh, Whitburn, Bacton, Winterton, Yarmouth, Penmon, Aberdovey, Groomsport, Newcastle, Tramore, and Ardmore; whilst others are in course of construction at Redcar, Fleetwood, Exmouth, Lossiemouth, and Dungarvan.

The total number of lives saved from shipwreck on our coasts during the past year, as stated in the Official Return of the Board of Trade, is as follows:—

By life-boats	206
By luggers, coastguard boats, and small craft	719
By assistance from shore with ropes, mortar apparatus, &c.	210
By ships' own boats, and steam vessels	394
By individual exertion of a meritorious character	26
Total	1,555

Although by these returns a much larger number of lives are represented as having been saved by ordinary boats, ships' boats, &c., than by life-boats, yet it must be borne in mind, as the officers of the Institution state, that the majority of such services have been performed under circumstances of little or no danger; whereas the life-boats are, for the most part, only called into requisition when the sea is too heavy and the wind too high for an ordinary boat to venture out. It has been reported to the Committee, by Coastguard officers and Lloyd's Agents, that upwards of *sixty* additional life-boats are required on the coasts. It may be reasonably anticipated, when the means for saving life on our shores have been thoroughly completed, that few lives will be lost from disasters at sea that could possibly be saved by human skill and exertion.

The total number of persons saved from shipwreck since the first establishment of the National Life-Boat Institution, and for rescuing whom the Committee have granted honorary and pecuniary rewards, is shown in the following list:—

In the Year	No. of Lives Saved.	In the Year	No. of Lives Saved.
1824	124	1842	276
1825	218	1843	236
1826	175	1844	193
1827	163	1845	235
1828	301	1846	134
1829	463	1847	157
1830	372	1848	123
1831	287	1849	209
1832	310	1850	470
1833	449	1851	230
1834	214	1852	773
1835	364	1853	678
1836	225	1854	355
1837	272	1855	406
1838	456	1856	473
1839	279	1857	374
1840	353	1858	427
1841	128	Total	10,902

This good work is not, of course, carried on without large funds, and we would urge the claims of the society to pecuniary support upon our readers. We take no pains to picture either the blessed consequences which attend its labours, or the calamities which it so successfully prevents. Each reader can do this for himself. All we say is, that he who has money to spare for a genuine work of mercy—a work free from those defects which taint very many of our so-called charitable societies — cannot possibly do better than bestow it upon the National Life-boat Institution.

THE ENFIELD RIFLE.

The impossibility of loading the Enfield rifle in India after the first few rounds, as alleged by the special correspondent of the *Times*, is placed altogether beyond doubt by the corroborative testimony which has reached this country from time to time. One example, quoted by Mr. Wilkinson in a pamphlet published some months since, may be taken as a specimen of the statements made by professional men upon the subject. An officer writing from Lucknow, April 7, 1858, after speaking of the number of Enfield rifles that have burst, "not only in action, but at simple ball-firing parades," says, "they all invariably, without one exception, go about four inches or less from the muzzle. Why or wherefore they so conduct themselves I cannot conceive, for I have suggested dirt, inversion of the bullet, foreign bodies, careless loading, &c., and each and all were disproved before my own eyes by careful men's muskets bursting without rhyme or reason, and this in an enormous per-centage to the force employed. *Add to this the impossibility of loading after a few rounds out here.* In the centre of infallibity (Hythe) you have a climate that produces a lubricity from the dirt, and scarcely impedes loading. On the plains of Oude, with the thermometer as high as an alderman's haunch of venison, and a dry pulverising air, the residium crystallizes instantaneously, and the product is a fair resemblance to an inverted nutmeg-grater, and renders loading *utterly impracticable.* Mind, I know what I am saying, and am unbiassed; moreover, I am enthusiastically fond of the Enfield and its practice, but in the two points I name (rather important ones), it is a failure as to an arm for the service."

This officer not only records the evil, but also throws much light upon the cause of it. It is the climate of India that occasions all the mischief. In the first place, the fatty matter composing the grease of the cartridge is to a certain extent dried up by the heat, while what is left of it is changed into a wax-like material which clings to the interior of the barrel and fouls it. Then, again, as this writer says, the residium is crystallized instantaneously in the dry air, and thus is produced a roughness which, of course, diminishes the bore, and prevents the entrance of the new cartridge, which, under the most favourable circumstances, would fit the bore with great nicety.

But why need we argue this part of the question? The fact is no longer, we believe, denied by the authorities at home. The evil is admitted, and in order to remedy it the diameter of the charge has been reduced. But hereby, unhappily, another and still greater evil has been produced, for the arm no longer possesses the indispensable quality of accuracy at considerable ranges. This will probably be denied also, and the results of Woolwich practice with the new ammunition will be brought against us. Forewarned of this, we must fore-arm ourselves likewise. And this we will do by stating fearlessly that the results of experiments sent forth from Woolwich are not esteemed reliable either by the public or by the gun-making profession. Whether there is anything in the atmosphere of Woolwich peculiarly favourable to good shooting, we do not know; but we do know that such shooting as is made there can nowhere else be obtained—in trials, that is, of arms to which the authorities are known to be favourable. This fact has been frequently tested, and we know not how to doubt it.

As a correspondent wishes to know "how the oval-bore Lancasters, supplied to the Ordnance, have answered," we must add a word or

Digitized by Google

two in respect to these weapons. The Lancaster rifles have answered admirably in the hands of the sappers in India. No complaints of any kind have, so far as we can learn, been made of them; on the contrary, they have been reported upon with unqualified favour. We make these statements on the authority of military officers who are able to speak to the facts from personal knowledge. Indeed, so far as the difficulty experienced in the loading of the Enfield rifle is concerned, a similar evil cannot occur with the Lancaster arm. This will be plain on consideration. In the Enfield rifle, a cylindrical charge has to be inserted in a cylindrical barrel. Consequently the smallest solid obstruction at any part of the bore throws the centre of the charge out of the centre of the barrel, and jams the one in the other. The Lancaster arm possesses a curious, but most important, immunity from this evil. In it, a cylindrical charge (the ordinary service ammunition) has to be inserted in an elliptical barrel, and the one therefore touches the other along two lines or two series of points only, viz., at the minor axis of the barrel. Consequently an obstruction, or even numerous small obstructions, may lodge themselves in the barrel without offering any obstacle to the descent of the charge. The fouling of this arm therefore is scarcely, if at all, possible all the time ordinary care is taken of it. And by ordinary care we mean such care only as troops can be expected to bestow upon their arms under the exigencies of arduous campaigns. Our troops in India, for example, as everybody has learnt from the *Times'* special correspondent, have been severely pressed. The rapidity and continuance of their movements have been so great that the men could not possibly keep their arms in their usual order. The arms should therefore be such as will retain their efficiency despite the unavoidable neglect of these Indian marches. This, we are confident, the Lancaster rifle will do. Of its accuracy we need not add a word, its decided superiority to the Enfield arm having been so frequently demonstrated lately in the official trials at Chatham and elsewhere.

In conclusion, we would ask—if the authorities really desire to render the Enfield gun as efficient as possible, notwithstanding its defects—whether it would not be worth their while to try if Captain Norton's gossamer cartridge will remove or reduce the evil experienced in Oude. We believe it would.

THE REWARD OF A MILITARY INVENTOR.

We sit down to write this article with peculiar feelings, having just returned from one of those philanthropic meetings at which the bright particular stars of our aristocracy are now wont to display their splendours. The voices of the Earl of Carlisle, the Earl of Shaftesbury, the Earl of Albermarle, Lord Radstock, and, above all (for the moment, at least), of Lord John Russell, still linger in our ears, and with them the "clink of compliment"—compliment to the working classes, of course! The aim of their persuasive eloquence was a very honourable one most assuredly, for it was that of establishing free drinking fountains for the masses throughout the metropolis, to the extent of 400 or more. Success to so sensible and serviceable a work! But it certainly seems a remarkable fact that while our governing classes have hearts so accessible to charitable emotions, and find so much time for "labours of love," they should be sadly insensible to that which, in our plain way, we prefer to charity—viz., justice and right! We say—with as much confidence as sorrow—that there is no civilized country under the sun in which the public administrators are more callous, more dead to common honour, not to say common honesty, than they are in England. Especially is this true in respect to their conduct towards that class of men to whom this country owes far more of its material greatness and security than to any other—the inventors and improvers of our mechanical arts. We verily believe it would be no exaggeration to say that we *kill* more men of this stamp than we reward.

This is, however, too large a subject to be treated here in any general way; we must, therefore, confine ourselves to the one case of improvements in military weapons, and to the one improver of them whom we had in our minds when we sat down to pen these lines, viz., the gallant and veteran Captain Norton. In the history of this officer's career, up to the present point, we have a succession of facts which rise up into a towering monument of dishonour—dishonour not only to the successive civil and professional chiefs of the military class, but also, we fear, indirectly to the profession itself. We could substantiate this statement by abundant evidence, gathered from sources which are not to be doubted; but in order to confine our remarks to the narrowest limits possible, let us name only a few of the more important of the gallant officer's inventions. To him we owe the so-called Minié bullet in its best form—the concussion fuse—the liquid-fire shell—and lead-coated projectiles—four things which have no parallels, in so far as their value to military science is concerned. We do not say we have openly received all these from Captain Norton. On the contrary, one great ground of our complaint is that we have obstinately rejected his offers of them, only to receive them (or most of them) later from the hands of others. A letter written by Lieut. Col. Beamish, in 1852, and published in the *United Service Magazine* for August of that year, sets forth the facts of the case, so far as they had then proceeded, in a very clear manner; and to this we must refer our readers. Besides this, the former and present volumes of our own Magazine bear ample evidence of the magnitude and success of the gallant officer's improvements. The *Journal of the United Service Institution* for November last likewise contains a résumé and description of many of them.

Here, then, we have a man of great and admitted merit as an inventor of military weapons, and one who still, in the advanced stages of his life, is affording renewed evidences of his zeal and skill daily, as the military columns of the *Times* have lately shown with much prominence—a man, therefore, who is lifted out of the category of those who by happy chances do us service, and ranks with those who benefit us by the life-long devotion of extraordinary faculties. And, more than this; for Captain Norton earned honours as a military officer in the six Peninsular campaigns, and shared the perils even of the "bloody Albuera," before he began his work as an inventor. And if even more be needed—to satisfy the predilections of the upper ten thousand—more may yet be said, for, upon the authority of Colonel Beamish, we may state that Captain Norton is the lineal representative of Parrice de Rynville, second brother of Thibbault (Theobald) de Rynville, Constable of Normandy, in the time of William the Conqueror. Parrice married the sole heiress of the Baron of *King's-Norton*, in Worcestershire, and took the name of *Norton*, according to the custom of the time. Captain Norton is, therefore, the representative of the Barons of King's-Norton, in the female line. (See Burke's Heraldry). In the family records, nearly three hundred years old, are the following Latin lines, which may have had their influence upon the professional choice and labours of the gallant inventor:—

"Est aliquid clarus magnorum splendor avorum,
Illud posteritas emula calcar habet."

Here the Government may surely discover sufficient claims for recompense and distinction. How is it, then, that such a man as this still moves about neglected amid the most generous people on earth? How is it that of all the millions granted annually by this nation for military services, not a fraction is spared for the reward of such services as his? Is it because we are ruled by a class out of most of whom all true honour has departed, and who can do nothing but clutch at place, and power, and perquisites for themselves—who have not even a blush left in them for deeds which would make the cheeks of poor men flame? Because, if it be so, it is high time that a hearty hatred and contempt of that class were engendered, and its place supplied by men of nobler spirit.

THE ARMSTRONG GUN.

There is so manifest a want of novelty in some of the principal features of the Armstrong gun that we are not surprised to learn that the granting of Sir William's patent has been opposed. Oppositions to it have been entered by several inventors. In consequence of this, and as there is much more to be said respecting the history, at least, of this gun than has yet appeared, and as, moreover, certain individuals are making an improper use of our former article, and some are even publishing volumes upon the subject—volumes containing nothing (except errors) in addition to what we there made public—we propose bringing together a mass of information respecting the gun in our next number. In doing this we shall draw largely upon papers drawn up at various times by Sir William Armstrong himself, and shall also point out the inventors who have forestalled him.

PATENTS FOR INSTRUMENTS AND MUNITIONS OF WAR.

The Government measure for putting the inventors of instruments and munitions of war more hopelessly than ever into the hands of official persons who know nothing whatever about such instruments and munitions, has passed both Houses of Parliament, and received the Royal Assent. In its progress it has undergone no change or amendment of any kind, except that in the printed Act the authors have taken our hint respecting Clause X., and instead of printing in the margin, as they did in the margin of the Bill, an unmeaning sentence, they have merely printed—"No *scire facias* to be brought." We have only now to watch the operation of the measure.

Parliamentary Proceedings.

CONDENSED FOR THE "MECHANICS' MAGAZINE."

THURSDAY, APRIL 7.

HOUSE OF COMMONS.

CAPTAIN KYNASTON'S INVENTION.

Sir G. Pechell called attention to the valuable invention of Captain Kynaston, R. N., for lowering boats, the value of which had lately been demonstrated on board H. M. ship Euryalus, when, a seaman having fallen overboard off Alexandria, the boat was lowered in a strong wind and heavy sea, the ship going eight knots through the water, and the man was saved. He (Sir G. Pechell) wished the right hon. baronet to obtain a report of the different trials made of Captain Kynaston's disengaging hooks, and, as rewards were given for valuable inventions for the destruction of life by means of explosive materials and large guns—as baronetages, and perhaps peerages, were the rewards of such inventions—it was certainly expedient that some due acknowledgement should be awarded to those who had projected the means of saving life. Captain Kynaston was suffering from wounds sustained in the Crimea, and his case was in every way deserving of consideration.

Digitized by Google

Sir J. PAKINGTON said the experimental trials of the invention were not completed, and the Admiralty were not yet in possession of any report on the subject. He sympathised most sincerely with Captain Kynaston under his sufferings, which were the results of valuable services rendered to his country, and he also felt grateful to that gallant officer for the endeavours he had made to bring to perfection a most useful invention for the preservation of life. He heartily hoped, for the sake of the gallant officer, that his invention might prove successful.

SIR W. ARMSTRONG'S GUN.

General PEEL proposed a supplementary estimate of £30,000 for the establishment of a manufactory of Sir William Armstrong's guns at Woolwich, to be under the immediate superintendence of that gentleman.

MR. MALLET'S MONSTER MORTAR.

Lord PALMERSTON asked what had been done with regard to the large mortar invented and made by Mr. Mallet. He understood that there had been several trials of this weapon, that in the main it had succeeded, and that, though parts of the mortar had at different times given way, these defects had been on each occasion remedied. At the last experiment one of the stays which held together the segments of which the mortar was compounded, being more tightened than the other stays, and having therefore to bear the whole strain of the explosion, gave way, but another stay was ready, and that accident was no proof whatever of failure. Hitherto, he understood, the mortar had not been tried with a full charge calculated to produce the greatest range of flight, and as yet no experiment had been made, by burying one of the shells to the depth to which it would probably penetrate when falling loaded at the end of its flight, and then exploding it while so buried, in order to see what would be the extent of the crater which the explosion would produce. He thought it exceedingly important that the weapon should be tried to the utmost, and he wished to know, therefore, whether these trials had been made, and, and if not, what reason existed for not carrying the experiments further, so as to ascertain the applicability of the mortar for warlike purposes.

General PEEL said he had had no notice of the question, and therefore could only speak from memory, but as far as he recollected an expense of nearly £13,000 had been already incurred in the trial of this mortar, and the last report of the Ordnance Committee was to the effect that they did not consider it advisable to continue these experiments. He did not say that the experiments should not be renewed, but at the present moment the Ordnance Committee did not think it advisable to incur any further expenditure in this way.

FRIDAY, APRIL 8.

HOUSE OF LORDS.

The Royal assent was given by commission to the Patent Law Amendment Bill (Munitions of War).

NEW MODE OF JOINING PIPES.

AFTER the meeting at the Institution of Civil Engineers, on the 29th ult., Mr. Siemens (Assoc. Inst, C. E.) exhibited a machine of his invention, manufactured by Messrs. Guest and Chrimes, for joining lead and other pipes by pressure only. The machine consisted of a strap of wrought iron in the shape of the letter V, and of three dies, two of which were free to slide upon the inclined planes, while the third was pressed down upon them by means of a screw passing through a moveable cross-head, embracing the sides of the open strap. The pipes to be joined were placed end to end, and a collar of lead was slipped over them. The collar was then placed between the three dies, and the pressure was applied, by means of a screw-key, until the annular beads or rings projecting from the internal surface of the dies were imbedded into the lead collar. The machine was then removed, and a joint was formed, capable of resisting a hydraulic pressure of 1,100 feet. The security of the joint was increased by coating the surfaces, previously to their being joined, with white or red lead. The advantages claimed for this method of joining lead or other pipes over the ordinary plumber's joint, were the comparative facility and cheapness of execution, as the cost of a joint of this description was said to be only about one-third or one-fourth that of the plumber's joint. A machine of a similar description was also used for joining telegraphic line wires, a specimen of which was likewise exhibited by Mr. Siemens.

CHESS AND DRAUGHTS FOR THE POCKET.—We are pleased to observe that a simple and ingenious combination of "men," &c., for playing these games has been produced especially for the use of the working masses. It comprises a flat box about four inches square, containing a folding board; also flat chess-men, stamped in gold on dark purple and white grounds, the reverse of which form draughts. All go easily in the pocket; and, for the convenience of the reader, we add, may be had post free, by sending seven stamps to Mr. Beal, 4 Grove Terrace, West Ham, Essex, E.

THE SURVEYOR OF THE NAVY'S REJOINDER TO LORD CLARENCE PAGET.

THE following documents have been prepared by the Surveyor of the Navy, in reference to Lord Clarence Paget's statement in the House of Commons on the 11th March. In a third column, we add our own explanations, which are in all respects confirmed by the Official Report, as will be seen:—

STATEMENT RESPECTING SHIPS ALTERED.

Lord Clarence Paget, March 11.

"The Lyra, the Racer, and other noble vessels, began life at 450 tons, but they gradually grew in size until they arrived at 750 tons, when they were launched."

"He would now ask their attention to a case which was almost incredible; some time ago, a frigate, the San Fiorenzo, was being built either at Deptford or Woolwich; she was a great favourite with the London folks, who used to visit her in large numbers, and a beautiful model she was.

"The First Lord asked where she was now? Why she had vanished into thin air—gone, he hoped, to another and a better world."

"Another case was that of the Immortalité, a 51-gun frigate, now being built at Pembroke; that unfortunate ship had gone through a deal of trouble; she was first of all lengthened amidships, last year orders went down from the Admiralty to lengthen her five feet by the bow; certain parties, he did not know who, but he had no doubt persons at Pembroke, thought that to lengthen a frigate five feet by the bow, would be to make an imperceptible alteration, and would have no effect whatever. We lengthened yachts 14 to 20 feet by the bow; but the authorities were inexorable, their orders were reiterated, and the poor ship was lengthened five feet by the bow. The result was as might be naturally supposed, that either the First Lord himself, with his fine nautical eye, or some other member of the Admiralty Board, saw, upon visiting her, that she was not fit to go to sea, and ordered her to be pulled down again and lengthened 15 feet."

"The Orlando, the Mersey, and indeed almost all that class of ships, had been treated in a similar manner."

"He wished to speak of the reckless alterations of new ships, their name was legion, almost every ship was altered; take the case of a three-decker, the Howe, 121 guns; she was laid down only last year or the winter before, but the dockyard people were now pulling her down to put a new bow upon her. Had any great improvement been made in the bows of ships within the last 2 years? Nothing of the kind had taken place."

Surveyor of the Navy, March 29.

The Lyra of 488 tons, and the Racer of 577 tons, were built in 1857 as originally designed, without having undergone any alteration, and none of the vessels of these classes built or building have undergone any alteration.

The San Fiorenzo, a 50-gun sailing frigate, designed by Messrs. Read, Chatfield, and Creuze, was laid down in June, 1850; she was in frame at Woolwich, and had a few streaks of her wales and diminishing plank temporarily fastened by screw bolts, when orders were given to take her down in 1856. She could not have been lengthened to convert her into a screw frigate on the slip on which she stood, it being too short; moreover, her form of section and scantling were ill-suited to such an alteration. Her timbers were in consequence reconverted for building the corvettes, &c., at that yard. The loss by reconversion could not have been considerable, but whether much or little, it was consequent upon the transition from sailing to screw ships. It would have been out of the question to complete this frigate as a sailing ship.

The Immortalité was laid down in November, 1849, and partly built as a 50-gun sailing frigate, and on the 9th June, 1856, she was ordered to be converted into a screw frigate, in the same manner as the Emerald had been, and the Melpomene was being converted, viz., lengthened forward, 5 feet; amidships, 33 feet 6 inches; and aft, 12 feet 1 inch. It was subsequently decided—viz., in December, 1857, to increase the length of the Immortalité, by the bow, an additional 14 feet, with a view of ascertaining beyond all doubt the value of that improvement by actual trial with her sister ship the Melpomene. Her bow was then only in frame. It was estimated that the difference of expense between lengthening the bow 19 feet at one operation, and doing it at two separate times would be about £200. The actual expense was £257 10s.

The Orlando and Mersey, the only ships of this class, were both begun in September, 1856, and were completed in strict conformity with the drawings without any alteration.

The Howe was ordered to be built in January, 1855, and in December, 1857, it was decided to lengthen her by the bow 15 feet, with a view of ascertaining, by actual trial with the Victoria, a similar ship, the advantage which would be gained by finer lines. She was at that time in frame only. This is the only ship designed for the screw during the last eleven years which has undergone any alteration. The actual expense of taking down the timbers, and retrimming and replacing them, was £384 5s. 3d.; and this is the only sum expended on all the screw ships designed within the last eleven years, which might have been saved if the views subsequently carried into effect had been adopted in the first instance.

The responsibility of having recommended to the Board the alteration in which this so-called wasteful expenditure was incurred, and about which so many erroneous statements have been made, rests with the Surveyor of the Navy.

B. W. WALKER,
Surveyor of the Navy.

Admiralty, 29th March, 1859.

From the MECHANICS' MAGAZINE *for March* 18, 1859.

The vessels Lyra and Racer have undergone no kind of alteration whatever.

The facts respecting this ship (the San Fiorenzo,) are very simple. Before the use of the screw became general, she was laid down at Woolwich as a sailing frigate 188 ft. 9 in. long. After she had been put into frame, and before her planking was nearly completed, it was proved advisable to discontinue building sailing ships of war. In order to convert her into an efficient screw ship, it would have been absolutely necessary to length-en her nearly 50 ft.... But unfortunately the slip at Woolwich would not admit of the extra length being added, and from the extreme narrowness of that dockyard at the building end of it, the slip itself could not be lengthened.... The only course left, therefore, was to take down the frame of the ship, and apply its timbers in the construction of some other vessel.

For the lengthening of the bow of the Immortalité, Sir Charles Wood was responsible, and has since made, in the House of Commons, the following statement respecting it:—"The fact is," he says, "the ship was in frame, and it was only necessary for the purposes of the alteration that a few bolts should be removed; the whole of the extra expense being the mere cost of additional labour. I may add that the reason why the change was made was to secure the advantage of her having fine lines at the bow." This statement is, we can assure our readers, perfectly true, and we need only add that the first lengthening of the ship amidships was absolutely essential to her conversion from a sailing ship into a screw.

With regard to the Orlando and the Mersey, we have only to offer an unqualified contradiction to Lord Paget's assertion. These vessels have never been lengthened or interfered with in any such way since their keels were first laid.

Of the first case adduced—that of the Howe—we have but little to say, because it happens that the alteration to which she has been subjected was never altogether approved by ourselves. That alteration, however, in the vessel has by no means involved the "pulling down" of the ship, as Lord Paget implies. And if no great improvement has been made in the bows of ships during the last two years, facts have been observed which induced the Admiralty to consider a further increase in the fineness of the bows of our large screw ships desirable; and it was in consequence of this, and not from mere wantonness, of course, that the change in the bow of the Howe is being made.

For building new vessels...	6,000,000	Expenses incurred in building ships.....	4,948,378
For sailing ships which might have been built...	400,000		
For converting sailing ships into screws.....	630,000	For converting sailing ships into screws.....	323,118
Wear and tear of ships in commission (an *average* number) during the 11 years, at 6 per cent. on the estimated cost	5,929,000	Making good defects, refitting, and fitting ships for sea and in commission (including the fitting, &c., of 309 gun-boats and other vessels, built by contract,) troop and store ships, yachts, tenders, &c.; fitting ships for the several divisions of the steam reserve, and in repairing ships	6,950,766
Maintaining ships in ordinary	550,000	Maintaining ships, hulks, &c., in ordinary.....	235,438
Estimated excess of stock of naval stores on 31st Dec., 1858, over 1848...	500,000	Value of stock of naval stores in the home yards on the 31st December, 1858, in excess of that on the 31st Dec., 1848...	1,550,000
		Expense incurred in foreign yards for the repair, &c., of ships (exclusive of coals).....	529,424
		Value of stores sent from England to foreign stations, not included in amounts for foreign yards	353,939
		Value of stores purchased by captains of ships in commission, consuls, &c., for the refit of the fleet (exclusive of coals)	340,000
		Expenditure under Votes 8 and 9 for extra pay to artificers of the fleet.....	91,436
		Incidental expenses, including those for navigating ships from one port to another, and for stores supplied to barracks, hospitals, victualling yards, &c.	157,1 2 1
		Expenses incurred in moorings, cables, buoys, &c.; transporting and docking ships, cranes, carts, capstans, &c.; repairs to Yard transports, lighters, barges, and boats; receiving, delivering, landing and shipping stores and timber; canting, carting, pitting, and issuing timber, &c.	2,469,747
		Stores supplied to other departments of Government and Foreign Powers, and to private individuals. Sale of Offal Timber, &c., paid into the *Exchequer*, and which formerly went in *aid* of Vote 10	1,057,639
		Vessels built by contract and purchased (exclusive of machinery)	2,666,404
		Surplus amounts on Votes 8, 9, and 10, in the years 1849-50, 1850-51, 1851-2, 1853-4, repaid into the Exchequer	627,034
		Amount of *unsettled claims* on Foreign Powers and private individuals	13,324
£14,009,000		Total of Expenditure	22,313,768
		Total of Votes brought forward	22,306,937
		Difference.....	6,831

The difference of £6,831 may be accounted for by the Expenditure for the Year 1858-59 being an Estimate based upon the Expenditure of the Three preceding Years, in consequence of the Accounts for the present Financial Year not being yet completed.

Admiralty, 29th March, 1859. B. W. WALKER, *Surveyor of the Navy.*

Statement showing the Aggregate Tonnage of Ships Built, of the Ships Converted, and of the Ships Fitted, between the 1st April, 1848, and the 1st April, 1859, together with the Cost thereof, as shown in the enclosed Accounts :—

	Tonnage.		Cost.
Ships built, including those converted into screw on the slip	209,408	...	£4,948,378
Sailing ships converted into screw ships in dock	54,700	...	323,118
Ships repaired; ships fitted for commission, for sea, for advanced ships, and for steam reserve; including those which were built by contract, or bought into the service, and subsequently fitted in the dockyards	914,371	...	6,950,766

B. W. WALKER, *Surveyor of the Navy.*

Admiralty, March 29th, 1859.

Besides these documents, the surveyer of the Navy adds a statement showing the expenditure incurred in each year for the various works and services performed from 1848 to 1859; a list of all ships and vessels built and converted in the Royal Dockyards between 1st of April 1848, and 1st of April, 1859; and a list of vessels built by contract and purchased, which have been completed and fitted for sea in the same period.

THE ESTIMATES OF THE ENGLISH AND FRENCH NAVIES.

*An Abstract of a Report of a Committee appointed by the Treasury to inquire into the Navy Estimates, from 1852 to 1858, &c.**

The authors of this report are Mr. G. A. Hamilton, Secretary to the Treasury; Mr. H. T. L. Corry, Secretary to the Admiralty; Sir R. M. Bromley, K.C.B., Accountant General of the Navy; and Mr. W. G. Anderson, Chief Clerk in the Treasury. Feeling that it belongs to the Cabinet alone to determine, on considerations of State policy the amount of force requisite for maintaining the naval supremacy of Great Britain, and the measures to be adopted for that purpose, they profess to have studiously avoided giving expression to any opinion of their own on such subjects, and to have confined themselves to the investigation and statement of facts. "It has been," say they, "our object to arrive at the utmost degree of accuracy as regards these facts; and we have offered only such suggestions as appeared to us to arise immediately out of the facts themselves."†

The total amount of money voted for the navy :—

In the financial year 1852 was		£5,835,588
,, ,, 1858		8,851,371
Vote 1, for Sea Wages	(in excess of 1852)	£858,374
,, 2, Victuals	ditto	482,850
,, 8, Artificers	ditto	299,992
,, 10, Stores	ditto	507,247
,, 11, New Works	ditto	320,722
,, 17, Services not Naval (transport of Troops)	ditto	282,900
		£2,752,285

Showing an increase of £3,015,783, being 51 per cent. on the votes of 1852.

This increase arises mainly under the following votes :—

The first illustration of modern additions to the expense of sea-wages which is adduced by the reporters is that which has been occasioned by the substitution of steam for sailing ships of war, and by augmented rates of pay given to certain officers since 1852. They present the following comparison between a sailing line-of-battle ship and frigate, and steam-ships of the same classes :—

	Guns.		Men.		£
1858, "Marlborough," steam	131	...	1,100	...	35,248
1852, "Britannia," sailing.....	120	...	970	...	26,693
Increase in 1858					8,555
1858, "Shannon," steam	51	...	560	...	19,341
1852, "Arethusa," sailing.....	50	...	500	...	14,585
Increase in 1858					4,756

A considerable part of the increase in the complement of men, as between a steam-ship and a sailing-ship of similar armament, results from the establishment of engineers and stokers, which is an addition to the ordinary complement for working the ship and her guns.

In the Navy Estimates it will be found that almost every vote is influenced by the number of men. An increase in the number of seamen involves a corresponding increase in the force of ships, in the expense of bringing them forward and fitting them for service, and providing for wear and tear. In the establishments at home, one cause of increase is the larger number of superintending officers requisite in the dockyards, victualling, medical, and other establishments, to superintend the additional men employed. Again, in the vote for artificers at home, which were in 1852, £666,929, in 1858, £966,921, the increase is attributable to the larger number of artificers and workmen employed in the dockyards, &c., in the present year. Take two items :—

	Artificers, &c., Employed.		Annual Increase.	Increase per cent.
	1852.	1858.		
Dockyards.....	9,960	12,215	2,255	22
Steam factories for repair of engines	1,046	2,361	1,315	125
Total	11,786	15,499	3,713	

* In preparing this abridgment we have excluded all matters which have no professional interest for our readers.

† It has been considered right to omit from the published Report various passages founded on confidential reports and communications made to the Government. The statements respecting the French navy are said to have been derived from authentic sources.

Digitized by Google

The addition to the rates of pay, likewise, of various trades has led to an augmentation of about £45,000, and new factories have been established at Sheerness and Keyham to meet the growing wants of the steam navy.

In the vote for Naval Stores, again, there has been an increase of 57½ per cent. It is obvious that in this vote, and in the votes for establishments and artificers in dockyards and factories, the question of the naval strength of England in ships of war is involved, as well as that of how far the large expenditure in our naval dockyards has been productive of an adequate return. As this is one of the most important subjects connected with the Navy Estimates, the reporters enter into some details explanatory of the causes of increase, having reference to all the years between 1852 and 1858. The number of men voted for the Navy affects peculiarly the votes for stores and artificers' wages, as the entire cost of fitting ships for sea, and of wear and tear, falls on the estimates of the year, whereas the expense of building new ships, however costly, is spread over a number of years. The cost of a new ship of the first class —the Duke of Wellington—is stated to be :—

For hull—labour	£30,652
„ materials	75,639
	£106,291
For masts, rigging, sails, stores	19,224
For engines and gear	46,220
	£171,735

But the maintaining rate annually is on :—

Hull	£6,377
Masts, &c.	3,748
Engines, &c.	4,200
	£14,325

Being more than 8 per cent. on the original cost, viz., 8 per cent. on hull and masts, and 9 per cent. on engines.

An increased ratio in the cost of maintenance appears to apply to smaller vessels, as will appear by the subjoined note.* Every additional ship, therefore, brought into commission in consequence of the vote which increases the number of seamen in the Navy, may be taken as entailing an annual charge varying from 8¼ to 9¾ per cent. on its original cost, which is expended in the purchase of stores and wages of artificers for maintaining it, thereby rendering necessary both an increase in the quantity of stores and number of artificers.

It is stated by the Surveyor of the Navy that, at the end of 15 years, on an average, the hull of each ship requires a complete and expensive repair; that the duration of a ship cannot be estimated at more than 30 years; that during the last 10 years 35 ships of the line and 46 frigates have been removed from the effective list of the Navy; and that on an average three line-of-battle ships ought to be produced every year merely to maintain the Navy on a proper footing as respects line-of-battle ships. The Surveyor of the Navy states that the present force in the dockyards, which comprises 4,000 shipwrights and apprentices, is not more than sufficient to build three line-of-battle ships, three frigates, and six sloops per annum, besides executing the necessary repairs to all the ships in the Navy. If, therefore, the naval supremacy of Great Britain is to be maintained, it is impossible to deny that a large force of artificers, and a large quantity of stores, materials, &c., must be kept up in our dockyards. The number of persons employed in the dockyards and factories at home, during the present year, is no less than 16,334 persons, including 1,279 convicts. The number employed in the steam factories has increased from 1,046 in 1852, to 2,361 in the present year.

Great efforts were made for several years before 1852 to increase the horse-power of marine engines. In the year 1851, the expenditure for steam engines did not amount to £100,000. In 1852 it exceeded £200,000; in the last six years £?,423,021 has been expended, giving an average of £570,503 a year.

The money votes in the six years from 1852 to 1858 for labour, timber, and stores, for the purposes of building and converting ships, and keeping the Navy in repair, exclusive of the purchase of steam engines and coal, and building vessels by contract, amounted to £14,105,096; the amount provided during the late war for building gun-boats and floating batteries, and other vessels, was £1,633,147, but a sum exceeding £3,000,000 was actually expended. The whole sum expended between 1852 and 1858, and voted in the latter year for labour, including superintendence and materials, but not including ordnance, amounts, it will be seen, to about £24,000,000.

With regard to the adequacy of the return for this large expenditure, the reporters observe that the greater part of the money expended on wages of artificers and the purchase of stores is, of necessity, applied to the general service of the fleet, such as fitting ships for sea, providing for wear and tear, for the purchase of coals, &c.; repairing ships, bringing ships forward for the several divisions of the steam reserve, and other such purposes, leaving only a limited sum available for the building and conversion of ships, and the purchase of new machinery. (See Appendix, No. 11, page 35.)

In the year 1852, the Navy possessed horse-power to the extent of 44,482, in the last six years it has been more than doubled, amounting now to 99,512; the number of steam-ships and vessels has increased from 177 in 1852 to 464 in 1858, the tonnage from 182,562 to 457,881; the guns from 3,045 to 8,246.

In 1852, England possessed afloat, building, and converting the following steam-ships, according to the report of the Surveyor of the Navy :—

	Number	Guns.	Horse-power.	Tonnage
Line-of-battle, 1st rates	4	484	1,600	14,113
„ „ 2nd rates	13	1,147	5,050	38,164
Block-ships	4	240	1,800	7,201
Frigates (including 7 now reduced to sloops)	28	620	11,497	41,435
Smaller vessels	86	536	19,817	65,444
	135	3,027	39,764	166,357

Total, 135, exclusive of 42 troop-ships and other steam vessels, making an aggregate of 177 steam-ships and vessels, 3,045 guns, and 45,064 horse-power.*

In 1858 England possesses, according to the report of the Surveyor of the Navy, the following steam-ships :—

	Number	Guns.	Horse-Power.	Tonnage
Line-of-battle ships :				
Completed	29			
Receiving engines	4			
Converting	6	4,735	29,050	155,885
Ordrd. to be convrtd.	1			
Building	10			
	50	4,735	29,050	155,885
Block-ships	9	540	2,800	16,033
Frigates (aftt. screw. 25 and buildg.) pddl. 9	34	1,239	18,690	75,308
Smaller vessels	309	1,688	44,888	173,433
	402	8,202	95,428	420,659

Exclusive of 62 troop-ships, store-ships, yachts, tenders, dispatch-vessels, &c., making an aggregate of 464 steam-ships and vessels, 8,246 guns; horse-power, 105,962, and 457,881 tons.

Of the steam horse-power there is :—

Appropriated	98,532
Unappropriated	1,330
	*99,862
To be supplied (but not yet ordered) for ships building	6,100
Total	105,962

The next class of expenditure to which the reporters direct attention is that comprised in vote 11, under the title of new works, improvements, and repairs of docks, &c. It contains provision not only for the maintenance and improvement of the numerous naval yards at home and abroad, with all their appendages of docks, slips, steam factories, machinery and storehouses, but also for the victualling establishments, hospitals, and marine barracks.

This vote was :—

In 1852	£265,140
In 1858	585,862
Increase in 1858	£320,722

being 120 per cent.

The alteration in the size and length of steam-ships of war which has taken place since 1852, necessarily involved expensive alterations in the docks and slips for the building and repairs of these vessels. The sums actually expended under this vote, during each year, have been £2,855,860. The estimate for 1858 is £585,862. Fortunately for the British Navy, by the foresight of the Admiralty in the year 1844, measures were taken to provide an extensive steam-factory and docks at Keyham (Devonport): £1,259,318 has been already expended on that great work; the estimate for its completion is £265,682, which may be spread over a period of five years. In addition to the works at Keyham, two new docks have been built since 1852; two are now building, five have been lengthened, and three are now being lengthened. Thirteen slips have been lengthened, one has been constructed, and three are now being lengthened. The cost of these improvements has been £388,451; and, in addition, more than £100,000 has been expended in gun-boat slips at Haslar and docks at Malta; 186 acres of land and 507 houses have been purchased as additions to the several dockyards, steam-factories, and marine barracks; £124,519 has been paid for these lands and houses. Many of these works are still in progress, and the expense of them may be spread over several years.

(To be concluded in our next.)

* A second-rate, as Agamemnon = 8½ per cent. A fourth-rate, as Euryalus = 8¼ per cent. A sixth-rate, as Curaçoa = 9¼ per cent. A sloop, as Harrier = 9¾ per cent.

* The small difference in horse-power between the amount specified in the table and the statement in the previous paragraph, results from some small engines not supplied.

Literature.

Transactions of the National Association for the Promotion of Social Science, 1858. Edited by G. W. HASTINGS, LL.B., General Secretary to the Association. London: John W. Parker and Son, West Strand. 1859.

THE promoters of the Social Science Association act very wisely in putting forth their transactions in the form of a compact and well-edited volume like that before us. The papers read at their annual gathering have a value which by no means expires with the occasion that calls them forth. A glance into this volume sufficiently proves this, if proof be needed. Here we have well-studied papers by many of the most famous men of the age. Brougham, Russell (Lord J.), Carlisle (Earl of), Shaftesbury (Earl of), Moncton Milnes, Kingsley, Ruskine, Sir James Stephens, Horace Mann, Canon Girdlestone—these are but a few of those who speak to us thoughtfully and earnestly through these pages. Nor do great men only address us; great women also afford us the advantage of their tender and considerate counsels. Florence Nightingale pleads for healthier hospitals, and tells us how to provide them; Mary Carpenter teaches us how to improve our ragged, industrial, and reformatory schools; and Mary Ann Baines expounds to her sex the means by which they may help the health of the nation. We have mentioned great names, but humbler ones are to be found here; Samuel Broome, for example, with his simple crown of crysanthemums upon his brow, stands up to tell us how the poor make gardens, and to pass yet another eulogium upon his pets—the working classes. The Society has been most fortunate in securing the services of Mr. Hastings as secretary. The truly admirable way in which this volume is put forth does him very great credit. It is larger than the first volume by more than 100 pages, but one does not see how it could have been made smaller without

Digitized by Google

sacrificing valuable matter. A wise man will undoubtedly add the book to his library.

Sketch of the Civil Engineering of North America. By David Stevenson, F.R.S., M.I.C.E., &c. *Second Edition.* London: John Weale, 95 High Holborn. 1859.

As we have so much engineering work before us in India and other "new countries" Mr. Weale has very properly thought it desirable to re-publish Mr Stevensons' volume, which, as he says, may be justly regarded as a "Sketch of Engineering Practice, applicable in New Countries." It is a work which no engineer, or student of engineering can do without. It affords very copious information respecting the harbours; the lake, river, and stream navigation; the canals, the roads, bridges, railways, waterworks, and lighthouses of North America. We recommend all our readers to obtain it, for there is not one of them whom it will not interest deeply and instruct usefully.

INSTITUTION OF CIVIL ENGINEERS.

March 22 and 29, 1859.

THESE two evenings were chiefly occupied with a paper on "THE MELBOURNE GRAVITATION WATER-WORKS," and a lengthy discussion thereupon.

April 5, 1859.

The first paper read on this evening was on "A NEW SYSTEM OF AXLE-BOXES, NOT REQUIRING LUBRICATING, AND WITHOUT LIABILITY TO HEATING," by M. Alphonse de Brussant. The improved axle-boxes were, it will be remembered, elaborately described and illustrated at p. 122 of the MECHANICS' MAGAZINE, for February 18, 1859, No. 8, New Series.

The second paper read was on "THE PERMANENT WAY OF THE MADRAS RAILWAY," by Mr. Bryce McMaster, Assoc. Inst. C.E. It was remarked that two leading features in the construction of railways in India were, the cheapness of those portions of the works which were entirely dependent upon native labour and the resources of the country, and the expense of those dependent upon England for the supply of materials. Among the latter of these was the permanent way, almost every part of which had, as yet, to be furnished from England. Thus, the portion of the Madras railway, from Madras to Arcot, being a length of 65¼ miles, had been constructed for £6,000 per mile, of which amount the permanent way alone had cost upwards of £3,000 per mile. On this portion of the line the earthwork, for a distance of 25 miles, was for a double line, and on the remainder for a single line only. All the bridges and culverts were for a double way. There was only a single line of rails laid throughout. The expense of freight, from England to Madras, for the first portion of the line was very heavy, owing to the Russian war. A reduction in these charges, as well as in the weight of the rails, would diminish the cost of the remaining portion of the line; although the greater distance to which the materials would have to be led, as the works were pushed on into the interior, would add to the cost as the line advanced. It was found that the Indian iron could not compete with the English, and that the Indian railways could not look for any considerable supply from local sources. But what the country could supply was material for sleepers, as its forests and jungles afforded a great variety of hard and durable woods, well adapted for the purpose. On the Madras railway, twenty-eight different kinds of wood had been used; all of which, with few exceptions, had been found to answer well, when carefully selected. The vibration of the passing trains, and the frequent opening out of the ballast by the workmen, seemed sufficient to prevent the attacks of the white ant. Creosoted fir sleepers, sent out from England, were found to be very durable; but their cost at Madras was 8s. 6d. each, or 9s. 6d. each when led fifty miles to the works, while the sleepers procured in the country varied in price from 4s. to 6s. 6d. each. A few thousand half-round Sál sleepers were kyanised, experimentally, with corrosive sublimate, at a cost of sixpence per cubic foot; but they were not found to be more durable than those of the same wood when unprepared. In the neighbourhood of Arcot granite blocks were used, but not to any great extent, on account of the roughness and rigidity of the road. Near the coast, one mile of line was laid with laterite, but the blocks were found to split, and their use was consequently abandoned. Some native-made keys and trenails were used, but the former were not pressed, and although they did very well in wet weather, in the hot season they shrank so much as to be unfit for use. The trenails, which were of teak, answered very well. In laying the road at first, the natives were found, in almost every other kind of work, intelligent and apt, when care and patience were taken in their instruction. The damage to the line from settlements and slips, from the effects of the monsoons, had been much less than was anticipated.

SOCIETY OF ARTS.

April 6.

THE paper read was on "EMBROIDERY BY MACHINERY," by Mr. George Wallis. The object of the paper was simply to give a popular description of the leading features of the embroidering machine, and to illustrate its practical use and capabilities by specimens of textile decoration produced by it. The paper was illustrated by a large number of fine specimens of machine embroidery, lent by Messrs. Houldsworth and Co., of Manchester, as well as by several working diagrams prepared by Mr. Wallis. Messrs. Wilson and Newton exhibited their Boudoir Sewing Machine. The Secretary called attention to an instrument, invented by the Rev. W. Taylor, for enabling the blind to work sums in arithmetic, and solve algebraical problems. A description of the instrument will be found at page 328 of the Society's *Journal*.

ROYAL AGRICULTURAL OF ENGLAND.

Monthly Council, April 6.

HIS Grace the Duke of Marlborough, President, was in the chair. The current cash-balance in the hands of the bankers was £2,206. The Journal Committee recommended that the paper on "POTATOES," by Dr. Lang, ordered to be reprinted, should be reduced so as to be published at a very cheap rate for the use of cottagers. Lord Berners, Chairman of the General Warwick Committee, reported to the Council the satisfactory progress made in the preparations for the Society's ensuing country meeting, to be held at Warwick in the week commencing Monday the 11th of July. Mr. Fisher Hobbs brought forward a motion to recind the resolution of the 5th of May last year. The Council divided, when it was found that the Council by a large majority adhered to their resolution of last year, in which the Local Committee at Warwick had already recommended that there should be no dinner at the Warwick meeting. Memorials were received from Canterbury, Croydon, Guildford, and Reigate, on the subject of the country meeting to be held next year in a district comprising Kent and Surrey. An Inspection Committee was appointed to visit the proposed sites, and report on their suitableness. The Council adjourned to the 13th of April.

ROYAL GEOGRAPHICAL SOCIETY.

April 11th, 1859.

A CROWDED meeting of this Society was held on Monday evening at Burlington-house, Sir R. I. Murchison, President, in the Chair.

ELECTIONS.—Viscount Emlyn, M.P., the Hon and Rev. F. S. Grimston, the Rev. James Booth, LL.D., the Hon. George Barrington, Captain T. Birch, R.N., Consul W. T. Pritchard, and E. C. Buckland, H. D. P. Cunningham, R.N., T. W. L Mackean, W. W. Montell, and W. Wheelwright Esquires, were elected Fellows. A very rare French atlas of Egypt, published by the Dépôt de la Guerre, in 1807, presented by Mr. Stephenson; and a diagram of Captain Selwyn's apparatus for paying out electric telegraph cables were exhibited to the meeting. The President regretted to announce that the hopes entertained for the safety of Mr. Adolphe Schlagintweit had proved fallacious, as it appears from papers which had been communicated by Lord Stanley, F.R.G.S., the Secretary for India, that he was barbarously murdered at Kashgar by a fanatic Synd, named Wolle Khan.

The papers read were:—

1. "ON A NEW PROJECTION OF THE SPHERE," by Sir J. F. W. Herschell, Bart., D.C.L., &c. Communicated by Sir R. I. Murchison. The author observes that his projection offers several, and among others the following:—"Peculiar advantages for geographical purposes, when the whole, or at least the whole accessible part of the globe, has to be mapped down on one sheet. For, first, it gets rid of the extravagant distension in high latitudes, at least on one side of the equator, which the mercator projection necessitates. Second. Like that and the stereographic projection it exhibits all small portions of the sphere in their true forms without distortion of figure. Third. It exhibits large portions (as whole continents) under very much less variation of scale where great amplitudes are concerned than the stereographic, and for the whole of one hemisphere than the mer[illegible] while for the other, as far as the 50th degree of latitude, it is no way offensive. Fourth. It takes in one view the whole accessible surface," &c.

2. "BRIEF REMARKS ON THE ISTHMUS OF SUEZ; WITH SPECIAL REFERENCE TO THE PROPOSED CANAL, &c." By Commander Bedford Pim, R.N., F.R.G.S. The author gave numerous reasons for considering the cutting of a canal across the Isthmus of Suez impracticable, and concluded with a proposal for shortening the route to India, by continuing the railway along the banks of the Nile, from Cairo to Assuan, and thence across the country to Berenice, thus effecting, according to his estimation, a saving of two days as regards time, and avoiding many delays, inconveniences, and difficulties.

The paper gave rise to a warm discussion, in which General Monteith, Messrs. George Rennie, Sidney, Lange, and Robert Stephenson took part, and the meeting was adjourned to the 9th of May.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

Ordinary Meeting, April 5th, 1859.

DR. J. P. JOULE, Vice-President, in the chair. The chairman exhibited several slips of paper, having messages inscribed upon them by Professor Thomson's new electric telegraph apparatus. In these specimens the marking consisted of a succession of minute perforations, produced by sparks from an inductive coil apparatus while the paper was gradually drawn through the machine. The sparks are directed to the paper by a fine platina wire affixed perpendicularly to a light arm attached to a small magnetic needle suspended within a coil of wire. The directive tendency of the needle is made very great by means of adjacent steel magnets. So long as either no current or a uniform flow passes through the coil, the perforations go on in a straight line. To produce signals, temporary electric currents of longer or shorter duration are transmitted. The magnetic needle carrying the platina wire is thus deflected, causing the line of perforations to assume the shape of a succession of letters V of various width and at various distances asunder, and in this way letters and words are indicated by the use of a given code of signals. The chief advantage of this system of telegraphic recording is, that it gives clear legible signals when a "relay" is entirely thrown out of action by inductive embarrassment. It has also the advantage of showing clearly signals superimposed on earth currents. The signal, superimposed either on the large swell or wave of induction or of an earth current, is like a ripple seen distinctly on a large wave. The chairman stated that Professor Thomson had recently discovered the means of giving a surer direction to the electric sparks, and of producing a very considerable increase in the size of the perforations produced by them. He also remarked that the system above described was similar in principle to that employed by Professor Thomson in transmitting the whole of the messages which had crossed the Atlantic from either side. To him, therefore, the merit of having given a temporary success to the Atlantic telegraph exclusively belongs.

Mr. T. T. Wilkinson, F.R.A.S., called the attention of the meeting to the existence of a very valuable manuscript in the Chetham Library, which he had been permitted to copy. It contains nearly forty letters on various mathematical subjects, by the Rev. J. Lawson, B.D., and the Rev. Charles Wildbore, M.A., editor of the *Gentleman's Diary*.

A paper was read by the Rev. Robert Harley, F.R.A.S., entitled, "THE METHOD OF SYMMETRIC PRODUCTS, AND ITS APPLICATION TO THE FINITE ALGEBRAIC SOLUTION OF EQUATIONS."

A paper was also read by the Rev. W. N. Molesworth, M.A., "ON COMPARATIVE SOCIOLOGY, OR THE APPLICATION OF THE COMPARATIVE METHOD TO THE INVESTIGATION OF SOCIAL LAWS." The author proposed the institution of a new science under the title of Comparative Sociology, in which all natural human societies should be comprehended under five great classes: 1. The wedded pair. 2. The family. 3. The community (whether village, town, or city). 4. The tribe or nation. 5. The world or mankind.

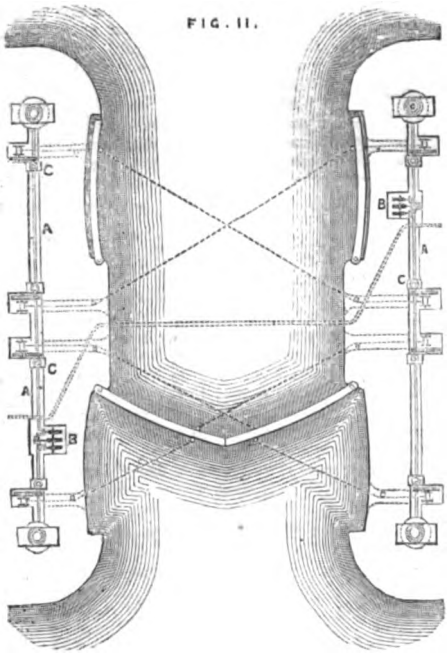
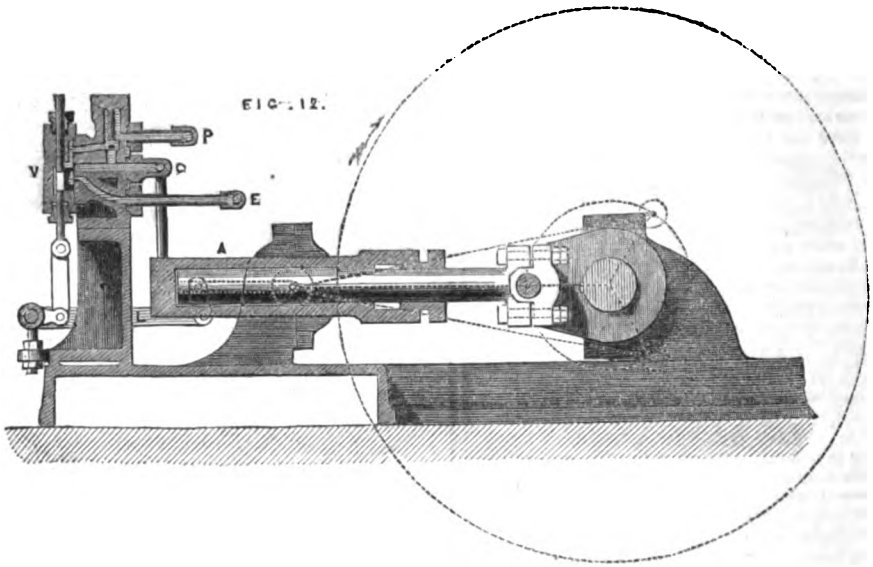
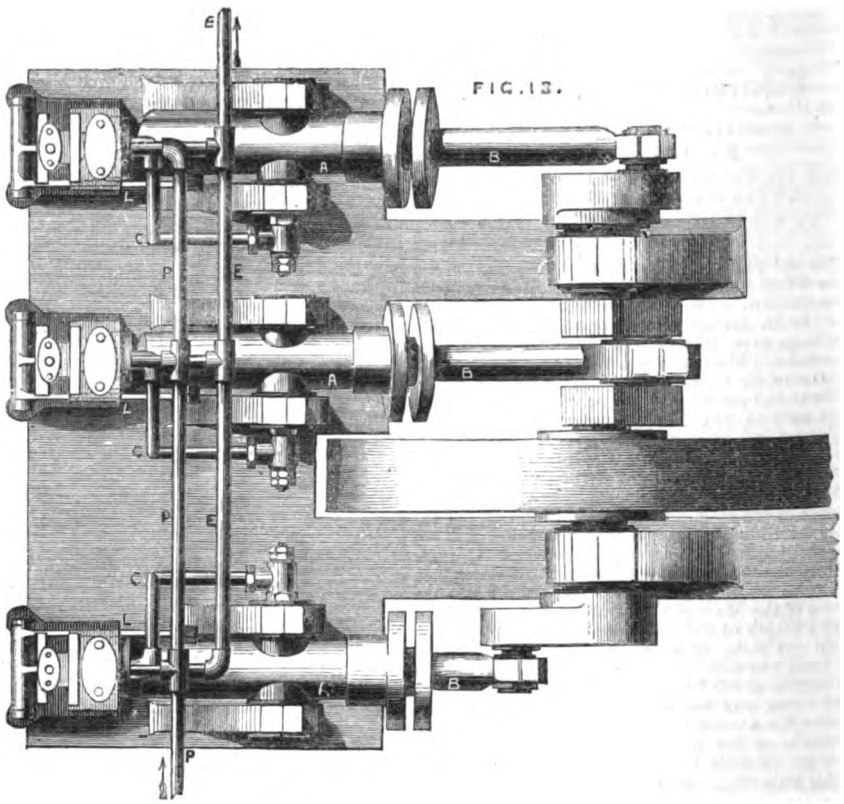
SIR WILLIAM ARMSTRONG'S WATER PRESSURE MACHINERY.







IMPROVED WATER-PRESSURE MACHINERY.

By Sir W. G. ARMSTRONG, C.E., F.R.S., Engineer to the War Department for Rifled Ordnance.

(*Concluded from page* 236.)

ANOTHER method has also been adopted for this purpose in some instances, which has been found to answer extremely well; Fig. 11 is a general plan of a dock entrance, showing the arrangement of the lock gate machinery. Instead of connecting hauling cylinders with each gate, a line of shafting *A*, driven by a small water pressure engine *B*, is laid beneath the surface of the ground, parallel with the coping on each side of the entrance, and by means of clutches is thrown into or out of gear with each gate crab. A wire from the engine extends the whole length of the shafting, so that the motion of the engine can be governed from the point where the work is being done. This method is already in use at several of the ports in South Wales, and is in course of being applied at the Jarrow Docks and the new dock at Silloth.

The rapidity with which dock gates can be opened and closed by these appliances is limited only by considerations of safety to the gates, and the operation is in practice usually performed in about two minutes.

The water pressure engines most recently constructed for driving the shafting consist of a combination of three oscillating cylinders working cranks inclined at 180° to one another, with slide valves simply arranged, as shown in Figs. 12 and 13; and a small engine of this description is exhibited to the meeting. The cylinders *A* are fitted with plungers *B* instead of pistons, and are therefore only single-acting. The slide valves *V* are worked by the oscillation of the cylinders, communicated through the levers *L*. When the back end of the cylinder is depressed, the slide valve is lowered and allows the water to enter from the pressure pipe *P* through the pipe *C* to the cylinders, where it acts upon the plunger in the out-stroke. In the return stroke, the back end of the cylinder being raised, the cylinder port *C* is closed to the pressure pipe *P* and open to the exhaust *E*. A small relief valve is provided in connection with the cylinder pipe *C*, opening against the pressure, which prevents any shock when the communication with the exhaust is closed at the end of the return stroke. These engines have occasionally been made with pistons, so as to be double-acting; but for the heavy pressures employed where accumulators are used the single-acting arrangement with plungers is preferred.

In nearly all cases in which hydraulic pressure has been applied for the moving of dock gates, it is also used for opening and closing the levelling shuttles, and in many cases also for working the capstans. The former purpose is effected by the direct application of a cylinder and piston fixed above the shuttle; and the latter is accomplished by throwing the capstan *C*, Fig. 11, into gear with the shafting *A*, or by applying to it a separate engine similar to that which has been described. A good example of the application of hydraulic pressure to the opening and closing of scouring shuttles may be seen at Sunderland Docks, where by means of this power the enormous area of nearly 500 feet is opened in a few seconds and closed with equal rapidity.

At the same place an example may also be seen of a heavy draw-bridge worked by water pressure. The bridge is supported upon wheels, and is first lifted from its bearings to such a level as to enable the wheels to roll back upon a suitable railway, both operations being performed with great steadiness by the action of the water in little more than a minute.

In working swing bridges by means of water pressure, a central press is applied to lift the entire bridge clear of its supports, and it is then turned by an application similar to that used for slewing a crane. The most remarkable specimen of a bridge of this description is one erected by the writer at Wisbech under the direction of the late Mr. Rendel. In this case an opening of 85 feet is spanned by a double roadway bridge in one leaf, weighing about 450 tons. At present it is but little used as a moveable bridge; but notwithstanding its great length and weight it can be lifted and turned it less than two minutes. The power is derived from an accumulator charged by hand labour, and it is expected that one man by continued working will be able to store up sufficient power for opening and closing the bridge as often as necessary. This system of using an accumulator in connection with a hand force pump has also been successfully applied to a drawbridge erected by the writer near Carmarthen on the main line of the South Wales Railway; and it might be advantageously adopted for many other purposes requiring a concentrated exertion of power with intervening periods of inaction.

Amongst the numerous applications that have been made of water pressure for the purpose of rapidly lifting and lowering heavy loads, there is one which calls for special remark on account of its growing importance: namely, its application in connection with an accumulator for working vertical hoists at the landing stations of steam ferries, in cases where a railway traffic is required to be passed over a river or estuary not easily crossed by a bridge. The traffic of the Aix-la-Chapelle, Dusseldorf, and Rhurort Railway is by this means shipped and unshiped at the ferry across the Rhine; and such is the rapidity and facility of the operation that a train of 12 coal waggons, weighing collectively 133 tons, can be transferred from the deck of the steamer to the railway, a height of about 20 feet in 12 minutes. Each

Digitized by Google

hoist lifts two waggons at a time, and raises its load in 10 to 12 seconds. These hoists are so arranged as always to accommodate themselves to the level of the boat, and always to stop at the exact level of the railway.

It is not necessary to say more upon that branch of the subject which embraces the two important principles of accumulation and transmission of power, by means of which a steam engine can be economically applied to give safe and rapid motion to a multiplicity of machines intermittent in their action and distant from each other. But it remains to notice the application made by the writer of the pressure derived from natural falls.

When the moving power consists of a natural column of water, the pressure rarely exceeds 250 or 300 feet; and in such cases he has employed to produce rotary motion, in preference to the original scheme of a rotary engine, a pair of cylinders and pistons, with slide valves resembling in some degree those of a high pressure engine, but having relief valves to prevent shock at the return of the stroke, as shown in Fig. 6 (page 220), already described. Where the engine is single-acting, with plungers instead if pistons, as in the water pressure engine already described, the relief valves are greatly simplified, and, in fact, are reduced to a single clack in connection with each cylinder, opening against the pressure, which is the same as the relief valve in the valve chest of the hydraulic crane. The water pressure engines erected by the writer at Mr. Beaumont's lead mines at Allenheads in Northumberland present examples of such engines applied to natural falls. They were there introduced under the advice of Mr. Sopwith, and are now used for the various purposes of crushing ore, raising materials from the mines, pumping water, giving motion to machinery for washing and separating ore, and driving a saw mill and the machinery of a workshop. In all these cases nature, assisted by art, has provided the power. Small streams of water, which flowed down the steep slopes of the adjoining hills, have been collected into reservoirs at elevations of about 200 feet, and pipes have been laid from these to the engines.

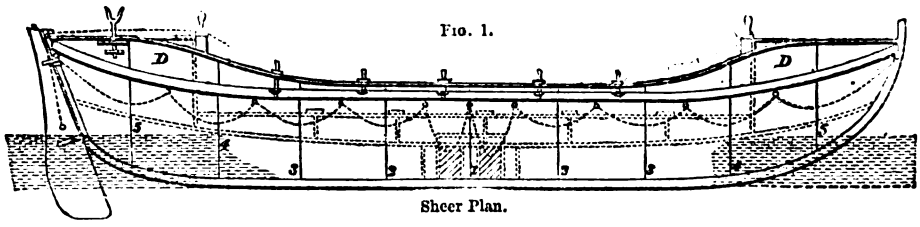
Another application of hydraulic machinery at the same mines is now being made in situations where falls of sufficient altitude for working such engines cannot be obtained, which from its novelty deserves special notice. For the purpose of draining an extensive mining district and searching for new veins, a drift or level nearly six miles in length is now being executed. This drift runs beneath the valley of the Allen nearly in the line of that river, and upon its course three mining establishments are being formed. At each of these power is required for the various purposes above mentioned, and it was desired to obtain this power without resorting to steam engines, The river Allen was the only resource, but its descent was not sufficiently rapid to permit of its being advantageously applied to water pressure engines. On the other hand it abounded with falls suitable for overshot wheels, but these could not be applied to the purposes required without provision for conveying the power to many separate places. Under these circumstances it was determined to employ the stream through the medium of overshot wheels in forcing water into accumulators, and thus generating a power capable of being transmitted by pipes to the numerous points where its agency was required. In this arrangement intensity of pressure takes the place of magnitude of volume, and the power derived from the stream assumes a form susceptible of unlimited distribution and division, and capable of being utilised by small and compact machines.

A somewhat similar plan is also adopted at Portland Harbour, in connection with the coaling establishment there forming for the use of the navy. The object in that case is to provide power for working hydraulic cranes and hauling machines, and more particularly for giving motion to machinery arranged by Mr. Coode, the present engineer of the work, for putting coal into war steamers. A reservoir on the adjoining height affords an available head of upwards of 300 feet; but in order to diminish the size of the pipes, cylinders and valves connected with the hydraulic machinery, and also with a view of obtaining greater rapidity of action, a hydraulic pumping engine and accumulator are interposed, for the purpose of intensifying the pressure and diminishing the volume of water acting as the medium of transmission.

In concluding this survey of the system of water pressure machinery which has grown to such large proportions, chiefly during the last seven years, the writer feels that the present occasion has afforded the fittest opportunity he could have taken of communicating the particulars contained in this paper; and he trusts that the details of the progress of this system may not have proved uninteresting.

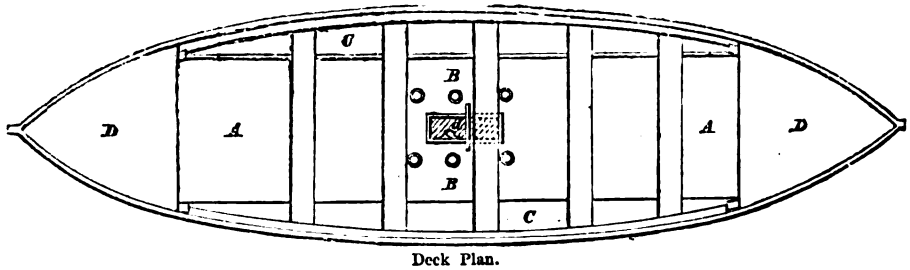
THE LIFE-BOAT OF THE ROYAL NATIONAL LIFE-BOAT INSTITUTION.

Fig. 1.



Sheer Plan.

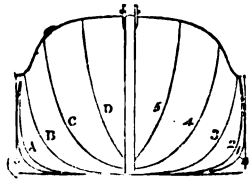
Fig. 2.



Deck Plan.

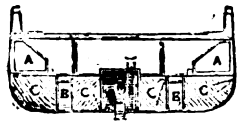
The accompanying figures show the general form, the nature of the fittings, and air-chambers of one of the boats referred to in our leading article. The boat is 30 feet in length, and 7 feet 6 ins. in breadth. In figs. 1 and 2, the elevation and deck plans, the general exterior form of the boat is shown with the sheer of gunwale, length of keel, and rake or slope of stem and stern-posts. The dotted lines of fig. 1 show the position and dimensions of the air-chambers within board, and of the relieving tubes. In fig. 2, *A* represents the deck, *B* the relieving-tubes (6 inches in diameter), *C* the side air-cases, *D* the end air-chambers. In fig. 3, the exterior form of transverse sections, at different distances from stem to stern, is shown. Fig. 4 represents a midship transverse section, *A* being sections of the side air-cases, *B* the relieving-tubes, bored through solid massive chocks of wood of the same depth as the space between the deck and the boat's floor. *C C* are spaces beneath the deck, filled up, over 6 feet in length, at the midship part of the boat, with solid chocks of light wood, forming a portion of the ballast; *d* is a section of a small draining-tier, having a pump on it, by which any leakage can be pumped out by one of the crew whilst afloat. The festooned lines in fig. 1 represent exterior life-lines attached round the entire length of the boat, to which persons in the water may cling till they can be got into the boat; the two central lines are festooned lower than the others, to be used as stirrups, so that a person in the water by stepping on them may climb into the boat.

Fig. 3.



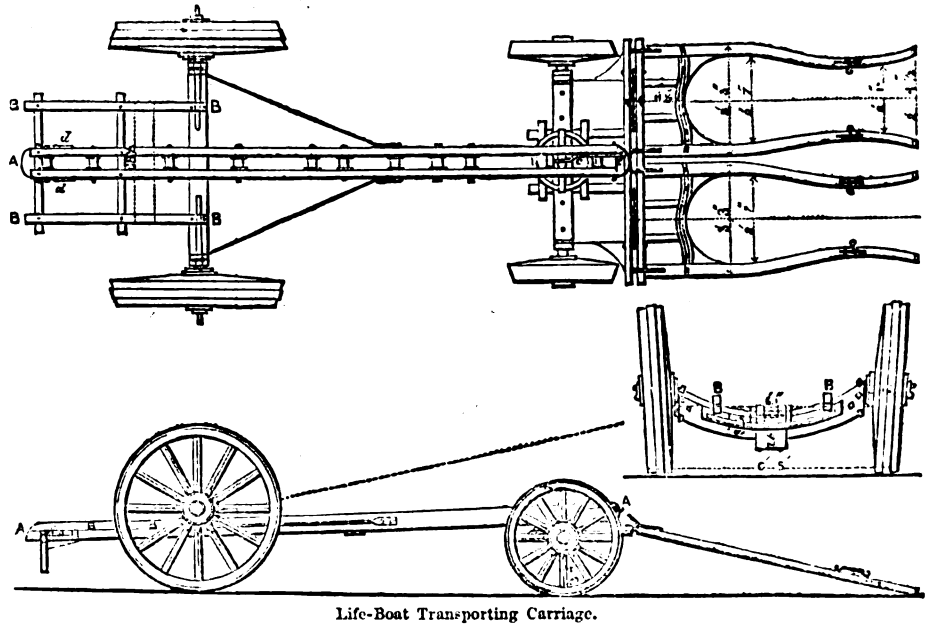
Body Plan.

Fig. 4.



Midship Section.

This life-boat possesses in a very high degree the qualities which it is desirable that a life-boat should possess:—1. Great lateral stability; 2. Speed against a heavy sea; 3. Facility for launching and for taking the shore; 4. Immediate self-discharge of any water breaking into her; 5. The important advantage of self-righting if upset; 6. Strength; 7. Stowage-room for a number of passengers.



Life-Boat Transporting Carriage.

In the remaining figures is represented the life-boat transporting carriage adopted by the Institution. The carriage consists of a fore and main body. The latter is formed of a keelway *A A*, and of slide or bilgeways *B*, *B*, in rear of the main axle, the boat's weight being entirely on the rollers of the keelway. Its leading characteristic

Digitized by Google

is that, on the withdrawal of the long forelock pin *C*, the fore and main bodies can be detached from each other. The advantages of this arrangement are that the weight of the boat when she is launched from the rear end forms an inclined plane by elevating the keelway, yet without lifting the fore body off the ground, whilst to replace her on the carriage she can be hauled bow foremost up the fore end or longer incline. The bilgeways *B*, *B* are needed at the rear end, that the boat may be launched in an upright position with her crew on board; but they are not required at the fore end of the carriage. The boat is hauled off the carriage, and launched into the sea by a rope on each side of the boat rove through the sheeve *D*, having one end hooked to a self-detaching hook at the boat's stern, and the other manned by a few persons on the shore, who thus haul the boat and her crew off the carriage, and launch them afloat at once, with their oars in their hands, by which means head-way may be obtained before the breakers have time to beat the boat broadside on to the beach.

SOCIETY OF ARTS.

ON THE PRACTICAL BEARING OF THE THEORY OF ELECTRICITY IN SUBMARINE TELEGRAPHY, THE ELECTRICAL DIFFICULTIES IN LONG CIRCUITS, AND THE CONDITIONS REQUISITE IN A CABLE TO INSURE RAPID AND CERTAIN COMMUNICATION.

BY S. ALFRED VARLEY, Assoc. Inst. C.E.

(*Concluded from page* 233.)

Previous to the first attempt to submerge the Atlantic cable, a series of experiments were undertaken by the company's late electrician, and the result published.* These experiments having been tried at the expense of the capital, and with opportunities which never before presented themselves, are too important not to be noticed, though it is believed that the author of them has lately had reasons to modify some of his conclusions.

The chief results published were these:—1. That no adequate result is obtained by increasing the sectional area of the conductor; that, in fact, in the case of a submarine circuit—a small wire will transmit signals more rapidly than a larger one. 2. That an insulated submarine wire conducts according to a different law to that of a suspended circuit. 3. That the rate at which a voltaic signal travels is not affected by the intensity of the battery. 4. That magneto-electric induced currents have the property of travelling in the first place faster than voltaic ones; and, unlike voltaic currents, when their intensity is increased their rapidity of travelling is increased also.

In the paper I submitted last March to the Institution of Civil Engineers, I pointed out what I conceive to be errors in these results, and endeavoured to show that some of them necessarily followed from the way in which the experiments were conducted, and I cannot more clearly express what I wish to convey on this head than by quoting my own remarks on that occasion:—

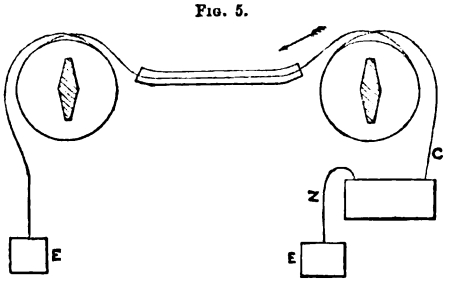
"In examining these conclusions, it has first to be considered whether the conditions of a submarine circuit and a suspended one are different. In a suspended wire, the insulating medium of the air takes the place of the putta percha of the submarine circuit. The earth, which is the nearest conductor, is a considerable distance off, and is only on one side of the wire, therefore but little induction can take place between the wire and the earth; nevertheless, induction to a certain extent does take place, and can be perceived in circuits of very moderate length.

"The author has noticed indications of it in a circuit 60 miles long, and he feels confident that with delicate apparatus it could be perceived in much shorter circuits. If the distance between the wire and the earth were decreased, induction would be developed more strongly, and the wire could be brought down step by step until the condition of a submarine circuit would be approached, where the earth surrounds the circuit on all sides, and is only separated from it by the thickness of one-eighth or three sixteenths of an inch of gutta percha—a substance possessing, moreover, specifically a much greater inductive capacity than air. It, therefore, appears, that the conditions are precisely the same, only differing in degree. Before proceeding further, and to prevent the possibility of mistake, it is desirable to make the following quotation from the work previously referred to† :—

"'The law of squares may possibly apply to the transmission of electricity freely along simple conducting wires, but it certainly does not apply to the case of its transmission along submarine and subterranean gutta percha covered wires (the facility of transmission being estimated by rate of speed), because in this the case is not one of simple conduction, but of transmission, after the wire has been charged inductively to saturation as a Leyden jar.' This quotation shows clearly the reason for concluding that small wires are better conductors for submarine circuits, as far as transmission is concerned, than larger ones; far the smaller the Leyden jar the more quickly will it be charged to saturation. The author, in differing from these conclusions, does not wish it to be understood that he thinks the law of squares is applicable to submarine wires; for he is not aware of any electrical phenomena which obey that law, but he submits that there is a material difference between a Leyden jar and a submarine wire.

"In a Leyden jar the inner and outer coatings are perfectly insulated one from the other. If they were not insulated there could be no statical charge, as is well understood by all electricians. Induction therefore *involves insulation*. But in a submarine circuit this is not the case. If the wire at the further extremity was disconnected from the telegraph instrument, and sealed up with gutta percha, the conditions would be nearly the same. In practice, however, it is quite open through the instrument to the earth, and the resistance opposed by the very long length of wire is the only insulation between the inner and outer coatings, for it unites both, being in connection with the earth at both ends (Fig. 5). It is therefore evident that if the wire offers no resistance there will be no insulation, and, as a consequence, no induction to retard the passage of the current. It is also equally plain that precisely in proportion to the resistance which the wire opposes, provided always the insulating medium be of the same thickness, will induction manifest itself and retardation be experienced.

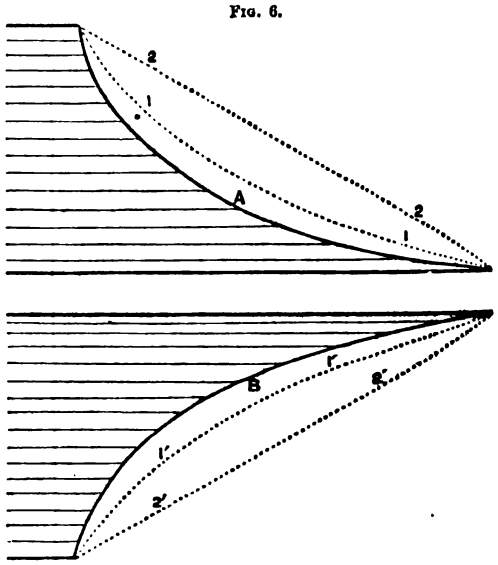
FIG. 5.



"There is also another difference between a Leyden jar and a submarine circuit. The Leyden jar is charged uniformly all over, whilst in a submarine wire the tension of the charge varies in different portions of the circuit, being at its maximum at the end where contact is made with the battery, and dying off to nothing at the further extremity."

The next consideration is the part induction plays in submarine circuits of any considerable length. In a submarine circuit the wire is insulated from the earth by only a thin layer of gutta percha; the conditions, therefore, are favourable for induction through the insulating material; the conductor itself, from its great length, opposes very great resistance, or, in other words, insulates to a very considerable extent. When a battery is connected to send a current, the first impetus is in part directed forward, in part diverted laterally; but as the wire opposes considerable resistance to the passage of the electricity which the battery can generate, whilst the thinness of the insulating material is very favourable for induction taking place through it, the greater portion of the first rush will be occupied in charging the wire statically at the battery end; as, however, it is a balance of forces between the resistance which the wire opposes on the one hand, and the ease with which lateral induction can take place on the other, a very minute portion must pass through instantly, and the period which will elapse between the making contact with the battery and the observing the current at the further extremity will depend upon the capability of the instrument to record very small quantities of electricity. In fact, immediately on contact being made with the battery, a wave will be formed throughout the length of the wire, somewhat like what is shown in the diagram (Fig. 6), which is intended to represent a submarine wire the moment after contact has been made with the battery. The line A represents the internal charge having its maximum tension at the battery end, and diminishing in intensity as it approaches the farther extremity. The line B shows the induced charge of the opposite kind on the outer surface of the gutta percha, and forms an exact counterpart to the internal charge, with the exception of being a little less intense; for as it is spread over a greater surface, and only exactly balances the internal wave, its tension will be less in proportion as its surface is greater. As the tension of the statical charge is raised, so will the flow of electricity at the further extremity increase; both will arrive at their maximum together; the current will then flow in a regular stream as long as contact with the battery continues. The dotted lines 1 1 and 1' 1' are intended to represent the waves after the contact has been made a short time, and the lines 2 2 and 2' 2' are intended to represent the waves when they have attained their maximum height. In the last case they will be perceived to be more regular. When the battery has been disconnected from the wire, the opposite waves will still continue to unite, but the rate of flow as the tension falls will become slower and slower.

FIG. 6.



In theory the time which would be occupied by a wire discharging itself completely in this way would be infinite. In practice the wire requires a very appreciable time to charge, and a longer period to discharge. The effect of this is, that if currents are sent at all rapidly one after the other, instead of obtaining a series of distinct impulses at the further extremity, an undulating continuous current is received; and, as to obtain a telegraphic signal, the wire has not only to be charged to a certain degree of tension before an appreciable current is received at the further end, but has also to be discharged afterwards before another signal can be sent, the impulses which are obtained through such circuits as these are very sluggish.

The problem to be solved is the best means of reducing the amount of induction, and of mitigating its effects. Almost the first remedy suggested when this inconvenience was experienced, was to substitute another insulated wire in the place of the earth for a return circuit, for it was argued that, as in this arrangement, one wire would be charged positively and the other negatively, they would neutralise one another. This suggestion was put to the test and failed. Since that time the same plan has been revived by several others; a good deal of argument has also been brought forward lately in support of it, and even amongst those who know its practical inutility, there would still seem to have been lurking some faith in the capability of the method (in theory at least) to neutralise the effects of induction.

The explanation of its failure, if we are guided by the first principles of the science, appears to me to be very simple, and I expect not only to make it plain that no advantage is to be obtained by the adoption of this method, but that it will increase the retardation.

Let two long gutta percha covered wires (Fig. 7) buried in the earth, be connected, one with the zinc pole and the other with the copper pole of a battery, and let the further ends of each of these wires be hermetically sealed. The earth, from its mass, being a perfect conductor, its action it is evident, will be the same as if metal tubes in

FIG. 7.

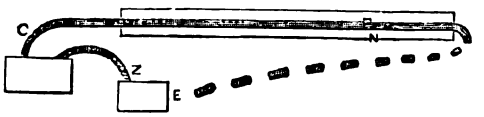
† *Vide*, "The Atlantic Telegraph," p. 23.

Digitized by Google

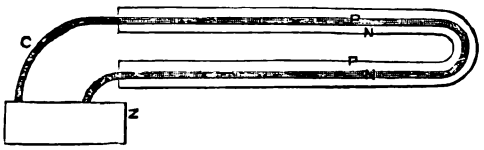
metallic communication with each other surrounded the gutta percha wires. It is therefore clear that the only retardation to induction will be the thickness of the gutta percha covering, and the tension of the statical charge will be in accordance with the intensity of the battery. Now consider the case of a similar gutta percha wire of the same length (Fig. 8) as one of these, but in which one pole of the battery is connected to the earth and the other to one end of the metallic conductor, and the circuit completed by connecting the further extremity to the earth. It will also receive a statical charge to a certain degree, but the tension of the charge will not, *ceteris paribus*, be dependent upon the intensity of the battery, but upon the resistance which the wire opposes, for it has already been shown that this is the only real insulation between the wire and the outer coatings, and that the degree to which statical charge can take place depends on the amount of insulation existing.

Fig. 8.



Now, let the ends of the two wires which are hermetically sealed be connected to each other (Fig. 9) the circumstances are quite as favourable for induction as in the wire in which one end was connected with the earth, but there will be twice the resistance; in other words, double the amount of insulation, and consequently, a proportionate increase in the amount of induction.

Fig. 9.



Another view of this matter will perhaps assist to confirm what has just been stated. It is a well-established fact that when a telegraphic circuit is composed of a loop of wire it will oppose the same resistance as a circuit of double the length where the earth is made use of in the place of a return wire, and this proves that the earth offers no appreciable resistance. If this be the case, what difference can it make whether the battery pole be carried to the end of the wire itself, or through the medium of any length of a perfect conductor, which the earth has been proved to be. Therefore, it would appears that the induction which would be manifested in a circuit composed entirely of an insulated conductor, would be the same as that in a circuit of twice the length, where one half the circuit is completed by the earth, and the only difference which would exist between the one and the other would be, that in a circuit composed entirely of wire, the statical charge will be distributed more uniformly throughout the entire length. But, says a writer on this subject, I admit that no advantage would result if two separate wires are used, and which will therefore necessarily be some distance apart from one another, but place the two wires in the middle of a mass of gutta percha (Fig. 10) and so close to each other that they may become virtually the centre of a system, and let the insulating material be of considerable sectional area, then no induction worth naming will take place between the wires and the earth, and the inductive influence of the positive wire will neutralise that of the negative wire.

Fig. 10.

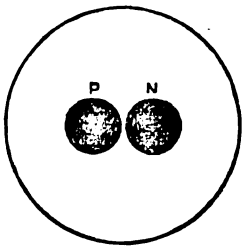


Fig. 11.

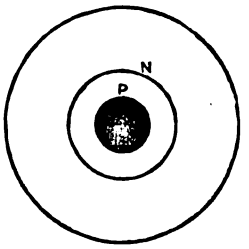

The fallacy of the proposition will be at once seen if it be carried out more fully. Instead of letting the wires lie side by side, let the one wrap over the other, and be, in fact, a tube with a thin mass of insulating material between it and the inner wire (Fig. 11). They will now become really the centre of the system, and fulfil completely the object desired by the author of this suggestion, but is it not evident that such an arrangement is the fac-simile of a Leyden jar, and will not the conditions be the most favourable that can be conceived for the development of induction?

The only remedy which has been successful in mitigating the effects of induction, is that of throwing into the wire, immediately after a current has been sent, another of the opposite kind; this absorbs and neutralises the preceding wave much more quickly than when the wire is left to discharge itself in the ordinary way. This method, however, does not reduce the induction, but only mitigates its effects, although in circuits of moderate length its adoption has, for practical purposes, completely removed the inconveniences arising from the induced charge.

There are only two ways of reducing induction, the one is to increase the thickness of the insulating material, and so render the conditions less favourable for its development, and thus approach the conditions of a suspended circuit, where the induction having to take place through a considerable space of air—a dielectric of very low specific inductive capacity—there is but little accumulation of statical charge, and consequently the impetus is almost entirely directed forward, and scarcely diverted laterally to any appreciable extent.

In gutta percha covered wires, when the insulating material is increased in size, it has been shown that the full effect of the increased thickness is not obtained, owing to the outer surface increasing at the same time.

There is also another quality possessed by resinous substances, and probably by gutta percha, worthy of consideration. It is the property of absorbing a charge in the mass of the substance, instead of its being confined entirely to the surface; the tendency of this will be to still further reduce the advantage of an increased thickness of insulating material.

A reference to first principles will make this clearer. All bodies insulate to a certain extent, and the only difference between a so-called conductor and insulator that would appear to exist, is a difference of degree, and if a charged body is brought into the neighbourhood of an insulated conductor, induction will take place through it in the same way as through a dielectric, but owing to the particles of conducting substances possessing the property of readily communicating their forces one to another, the inductive force developed at the further extremity will, within certain limits, be scarcely affected by the length of the conductor through which induction is taking place. The absorption of a charge within the substance of the dielectric is an approach to this condition, but its practical moment when gutta percha is the insulating substance has to be determined by experiment.

Lessening the induction by reducing the resistance has next to be considered. The first thing obviously will be to obtain a metal of the highest specific conducting power, for could the sectional area be diminished without increasing the resistance, the induction would be reduced proportionately to decrease in the surface. The next will be to increase the sectional area of the conductor, and although this involves increased surface, yet there will be a gain; for when the diameter of a wire is enlarged, the surface over which the amount of induction extends does not increase in the same ratio as the sectional area which determines the resistance opposed by a conductor. To make this clearer, let four cables ranged side by side be employed as one conductor. Such an arrangement will possess four times the sectional area, and oppose only one-fourth the resistance; in other words, the same tension of current will force through four times the dynamic quantity of electricity that would be generated through the single cable when used alone. Signals would not, however, be transmitted more rapidly through the four cables than through the one, for although the conducting power has been increased four times, the surface has been quadrupled also, which will exactly counterbalance the lessened resistance; but merge the four into one, the external inductive surface will then be halved, whilst the sectional area will remain the same as before, and there will be only half the induction manifested. It therefore follows when a wire is enlarged, that as the sectional area increases as the square, whilst the surface increases only in regular proportionals, the relative balance of forces in favour of rapidity of conduction will, in a submarine conductor of a given size, be twice the amount of that in a wire of half the diameter.

I would now attempt an explanation of how it happened that an actual retardation was observed in some of the experiments with the Atlantic cable when a conductor of enlarged sectional area was employed; and on this head I would again quote from my remarks on a former occasion:—

"In the experiments to ascertain whether any advantage would result from the use of an increased sectional area of metallic conductor, recourse was had to joining the cables side by side, the increased inductive surface which such an arrangement involved having possibly been overlooked. This will account not only for an increased speed not having been obtained, but for an actual retardation having been noticed. Electro-magnetic induction coils do not create electricity, they simply offer a ready means of converting electricity of low tension and considerable dynamic quantity into electricity of very high tension and small dynamic quantity. The quantity evolved by them is always smaller in proportion as the intensity is greater. Both cannot readily be obtained together and if a very high intensity is required, the quantity must be sacrificed, unless the size of the apparatus is immensely increased. This difficulty has evidently been appreciated, as the induction coils used by the Atlantic Telegraph Company are of large size and great length, so as to obtain high tension with an appreciable dynamic quantity. Nevertheless, there is little doubt but that the quantity evolved even by these machines, when compared with that generated from voltaic batteries, is small. This being the case, on giving the current a larger number of channels to rush into, there is not enough electricity to fill the wires, consequently the tension of the current will be very much lowered. The effect of this will be that a longer time will elapse before the tension of the wire will be raised sufficiently high at the further extremity to render itself apparent on the instrument. To obtain under such conditions, the same speed with four cables as would be obtained with one alone, it would be necessary to employ four of these induction coils, ranged side by side, and worked with four times the battery surface, so as to generate four times the dynamic quantity of electricity. When qualified with these conditions, under which, no doubt, the experiments were tried, the reasoning contained in the Atlantic Telegraph Company's pamphlet, giving in an earlier portion of this paper, is correct. It is precisely a case of having four Leyden arrangements to charge instead of one. A telegraph cable is, in fact, a Leyden arrangement, which has to be charged to a certain degree of saturation before signals are obtained. The degree to which it has to be charged, statically, depends upon the extent of inductive surface compared to the conductibility of the metallic core. In a circuit where the conductibility of the metallic core is very great, compared with the inductive surface of the insulating material, no high degree of statical charge can take place, and signals will pass quickly. The opposite effect will be noticed in a circuit where the inductive surface is very large compared with the conductibility of the metallic core. The wire will then have to be statically charged very highly, before a perceptible current will flow from the further extremity, and signals will be obtained proportionately more slowly."*

The reason why signals are found to pass when magneto-electric induced currents are employed in place of voltaic ones arises, I believe, not from any specific difference between them, but simply from the tension of the induced currents being very much greater than any voltaic ones which have been employed. On this head I will say nothing further here, but would refer those who may take an interest in it to my paper of a former occasion, where I have fully entered into this subject, and also attempted an explanation of how it has happened that in the experiments with voltaic currents, of varying intensities, no difference of speed has as yet been observed.

The amount of retardation which will be experienced in submarine circuits possessing conductors of varying resistance, and insulated with different thicknesses of insulating material, it appears to me can, comparatively speaking, be readily determined by actual experiment. I have for a long time been engaged in designing an apparatus for this purpose, and at the time I arranged to give this paper, I fully expected to have had the apparatus completed by this time, and to have been able to have laid it before you on this occasion; and, though I regret not being able to do this, yet I feel I have sufficiently advanced to warrant my explaining the principles of its construction. The principles upon which it is based are: that a body which offers the same resistance as another, without reference to its substance or length, may, as far as conducting power is concerned, be considered electrically the same. If we make use of a substance or metal of any inferior specific conducting capacity to that of the metal employed in submarine circuits, and also of greatly diminished sectional area, the same resistance as that offered by the very longest circuits can be obtained in a very small compass; and such an arrangement will, as far as simple conducting power is concerned, fairly represent a long submarine circuit.

The induction which manifests itself in submarine circuits can also be obtained

* *Vide*, "The Atlantic Telegraph."

Digitized by Google

if the conditions for its development are as favourable as they are in submarine conductors.

The apparatus consists, 1st, of a series of resistances, the values of which are known. 2nd. Of a series of induction plates, the values of which, when compared with a given surface of a gutta percha coated wire, are also known. 3rd. A mechanical arrangement to accurately measure minute periods of time. By a combination of the resistances and the induction plates, a conductor, which will fairly represent a submarine circuit, will be obtained. The resistance can be diminished or increased, and the inductive surface can be doubled or halved at pleasure, and thus circuits with conductors of varying lengths and sectional area, and different thicknesses of insulating material be imitated, and the law which governs the retardation in the transmission of telegraphic signals determined by direct experiment.

It may be argued that as the inductive surface in a telegraphic circuit is uniformly spread throughout, a series of induction plates will not present the same conditions, but it is evident that they may be divided throughout also, and although they will not then precisely represent what is actually the case, the result will approximate very closely to those obtained from a submarine conductor. Perhaps it would have been prudent not to have called attention to an apparatus before its completion. I have done so, however, because I have felt it was due from me to endeavour at least to point out how some of the important problems involved in submarine telegraphic communication between distant stations may be resolved.

The chief deductions from what has been brought forward in this paper are:—1st. That the metallic core of a submarine cable should be composed of a conductor of the highest specific conducting capacity. 2nd. That a decrease in the retardation which is caused by the induction that takes place in submarine circuits, can only be obtained by increasing the thickness of the insulating material, but that it will be better to do this by enlarging the sectional area of the conductor as much as is practicable. In designing a cable there are many considerations besides these of its simple electrical qualifications which have to be entertained. The object to be obtained is the best result with the most economical investment of money. Are the proportions which were adopted in the Atlantic cable the best to insure this? The weight of the conducting coil in this cable is about 03 pounds to the mile, the value of which, speaking roughly, would, I suppose, be about as many shillings. When served with gutta percha its value was raised £40 per mile. The iron sheathing and getting the cable on board brought its value up to £100 per mile. The expenditure, however, did not cease here; there was the hire of ships, salaries of staff, &c., &c. In this cable, therefore, only 4 per cent. at the outside was invested in the conductor upon which the transmission of the messages depended. If the views which I have brought forward are correct, a conductor of double the diameter would only produce half the amount of retarding force of one of half the size. Such a conductor, at the very outside, would not cost more than £16 per mile, and the increased expenditure, in serving such a conductor with gutta percha, and giving it an iron sheathing, would not, comparatively speaking, be very large; the expenses of the staff and the hire of ships would be about the same in both cases; the latter would be, perhaps, increased slightly, but not to any material amount.

THE TAXES ON KNOWLEDGE.

WE request the attention of our readers to the following address of "The Association for Promoting the Repeal of the Taxes on Knowledge, to the Electors of the United Kingdom."—"Fellow countrymen,—The annual 'ministerial crisis' has brought public business to a stand. You will, therefore, shortly be called upon to elect a new House of Commons. No administration proposes to reduce the public burthens, or to relieve the producing classes from indirect taxation, which presses upon them in a ratio far exceeding the proportion of their income. Among these taxes one stands pre-eminent as the only remaining excise duty on a manufacture. It has been abundantly proved that the paper duty is a tax upon literature, an obstruction to education, an impediment to commerce, and a hindrance to production; that it interferes with the process of manufacture, represses industry, and injures the revenue. Pledge, therefore, every candidate to vote for its repeal. Signed by order of the committee and on their behalf.—RICHARD MOORE, Chairman, 25 Hart-street, Bloomsbury, C. D. COLLET, Secretary, 10 Ampton-place, Gray's-inn-road, London, April 6th, 1859."

THE ENFIELD RIFLE CARTRIDGE.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The difficulty of loading the Enfield rifle arises from the surface of the leaden shot oxidysing, and thus increasing its diameter. If the shot is coated with thin tough paper pasted on its cylindrical body, and a little forward on its conoidal front, the lead cannot then oxydise, and the shot preserves its proper size in all climates. The oxyde of lead is a poison, and causes wounds to mortify. This fact ought to be made known generally, and without any delay.

April 4, 1859. J. NORTON.

CUNNINGHAM'S PATENT SELF-REEFING TOPSAILS.

THE judgment pronounced in the action brought by Mr. Cunningham against MM. Brouard and Son, in the Civil Court at Havre, for an infringement of the patent obtained by Mr. Cunningham on the 1st Sept., 1851, is so remarkable for its decision and completeness that English patentees should undoubtedly be put in possession of it. The following is a translation of it, as reported officially in the *Courrier du Havre*:—

1. "Whereas Cunningham obtained, September 1st, 1851, a patent of invention, which will expire November 30th, 1864, for a system of reefing sails, and asserts that Brouard and Son have introduced on board several ships, to wit the Guillaume le Conquérant, Captain Bigot, a system based on the same principle and producing the same effect; that there is consequently an infringement; and that he, therefore, claims that Brouard and Son should be bound, under a penalty of 5,000 francs, to give up to him the sails and rigging fitted on board the ship Guillaume le Conquérant; that they should be forbidden to fit similar sails, and condemned to substantial damages according to law;

"Whereas Brouard, jun. (son), pleaded in the first place that he was not a party to the suit, as having no share in the invention of Brouard, sen. (father), or in the patent taken out by him, and was not even the partner of Brouard, sen.:

"But whereas this last assertion is not correct, it being, in fact, proved by a copy of the extract deposited at the office of the Tribunal of Commerce of an act of the 22nd November, 1855, that a partnership had been entered into for five years between Brouard and Son for working the sail-making factory belonging to Brouard, father; that it matters little in whose name the patent of invention was taken out; that it is clearly Brouard and Son who work the patent, and who have made the infringement, if there has been one—Brouard, Jun., must consequently be a party to the suit:

"Whereas according to the 2nd article of the law of July 18th, 1844, the discovery of new means, or the new application of known means for obtaining a result, is to be considered as an invention; that this same law refers to the improvements which may be made in a patented system; that during the year, dating from the delivery of the patents of invention, none but the principal patentee can take out a patent for any improvement, alteration, or addition to the patented invention; that, at the expiration of the year, a second party may, on the other hand, take out a patent for any alteration, addition, or improvement, but cannot work it during the time of the first patent, and neither can the first inventor, on his side, use the improvement, so that if the first inventor wishes to add the improvement to his discovery he must apply to the second, and the second inventor must in like manner apply to the first for the system to which he wishes to adapt his new sort of improvement.

"Whereas, finally, the same law has declared the patent null, if the discovery, invention, or application be not new:—

2. "Whereas the Cunningham invention consists in a system by which the sails are reefed and unreefed by means of ropes or chains worked from the ship's deck, and the principle of which is, the rolling the sail on the yard, by means of the self-acting motion of the yard, which rolls on itself in consequence of the gravitation owing to its own weight, joined to that of the sail, and to the resistance given to the motion by a special apparatus:

"Whereas Brouard, father, maintains that the principle, the mother idea, of the Cunningham invention, has long been public property, in proof of which assertion he brings forward the blinds; but that this argument is faulty, as blinds do not work by gravitation, but by a mechanism which rolls the blind round a fixed rod; that Brouard, father, alleges, in addition, that in 1822 the Marquis Ducrest introduced at Havre a system for sails of which the Cunningham invention is only a copy; that he asks to be allowed to give proofs of this, but the facts produced do not appear pertinent; that it is not even alleged that in the Ducrest system the rotation of the yard producing the reefing of the sail was owing to a combination of gravitation with a certain resistance; that under every view, therefore, the Cunningham system is a new invention, or at least a new application of known means:

"Whereas the conduct of Brouard himself is contradictory to his first plea, as he did himself take out a patent of invention after Cunningham for a system which, as will be proved, is based upon the original idea of the Cunningham system:

"Whereas it is sufficient to examine the registered specification of the Brouard sail, the Cunningham patent, and the models placed before the Court to recognise that the principle of the Cunningham invention has been copied by Brouard; that the sail of the latter rolls round a yard in consequence of the gravitation due to its weight, which, combined with the resistance caused by the appliances for producing the motion, produces the rotation of the yard; that such is the original idea of the Cunningham invention; that it matters little that there is some difference in the execution, and that the Brouard sail is rolled on an auxiliary yard, and not on the yard itself, as in the Cunningham sail, and that the appliances for producing rotation are not fitted to some part of the yard; that these are matters of detail, not sufficient to prevent its being an infringement: neither can any weight be attached to the circumstance of the Cunningham sail being divided in the middle, for a part of its depth, while the Brouard sail is whole, the bosses for rolling being fitted to the ends of the yard; that this may possibly be an improvement, for which Brouard might perhaps have been able to take out a patent of improvement, but not to work it during the time of the Cunningham patent; that the infringement alleged by the said Cunningham is, therefore, established; that the patent of invention obtained by Brouard cannot be of any consideration in the suit; as far as giving damages, and the prohibition to use sails similar to those fitted on board the Guillaume le Conquérant, there can be no difficulty, but there is not sufficient evidence before the Court to determine the amount of damages:

"Whereas concerning the seizure of the sails of the Guillaume le Conquérant, where the infringement is proceeded against, correctionally, the confiscation of the pirated article is a punishment which can be inflicted on the person infringing the patent, but that in the civil court no punishment can be pronounced; that the Civil Court, satisfied as to the question of infringement, cannot properly order the confiscation of the article, it can only, by way of indemnity, order the pirated article to be given up to the inventor, under a penalty; that this must, therefore, be decreed in the Cunningham case, the tribunal not being able, however, for want of documents, to determine the amount of the penalty:

3. "For these reasons, the Court of Common Pleas in the first place refuses the plea of Brouard, jun., to be dismissed from the suit, and decrees that the sails fitted by Brouard and Son on board the Guillaume le Conquérant is an infringement of the system for which Cunningham took out a patent September 1st, 1851; declares Brouard and Son non-suited in their plea for the nullity of Cunningham's patent; prohibits them from fitting similar sails in future, during the time of the Cunningham patent; and condemns them to pay those damages to which the said Cunningham is entitled according to law; orders Brouard and Son to give up to Cunningham, under a penalty, which the Court will afterwards determine, the sails fitted on board the Guillaume le Conquérant, and condemns them besides in costs."

A NOVEL METHOD OF TELEGRAPHING.

Three gentlemen (S. Hoga, W. P. Piggott, and S. Beardmore) lately obtained provisional protection—which they subsequently abandoned—for a peculiar invention applicable to telegraphs communicating from land to land, through intervening water. They proposed to carry it out by wires, either insulated or uninsulated, and considered it capable of being applied to some of the present submarine telegraphs without interfering with existing arrangements. In such cases it was proposed if desirabe to transmit messages at the same time as others resulting from the current formed by existing batteries. The battery was to consist of one great cell, and they made "the sea or other water in combination with a negative and positive element at either end, one mighty battery." This they effected by placing in the sea, near each shore, one of the negative or positive elements. These two elements were connected by a wire or cable, either insulated or uninsulated. "When the wire," said they, "is in contact with one element only, there is no current of electricity between the negative and positive elements, but as soon as the wire is in contact with both, the curcuit is completed, viz., from the negative through the whole sea or water to the positive, and from this, through the wire, and back to the negative."

Mr. B. Jones, an ironfounder of York, has introduced a method of employing, as press wheel rollers or clod crushers, two or more external rollers, working in the same plane, and fitted with internal rollers to correspond, the external rollers being formed with blades or crushers of hammered iron. When the rollers are set in motion, the internal rollers fit into the space between the blades, and are carried round in a direction contrary to that of the external rollers, their operation in this respect being similar to that of ordinary spur wheels. The earth and other matter is thus prevented from adhering to the blades of the roller, which enables it to be used as well on wet as on dry soil. By employing hammered iron the efficiency of the implement is increased, and its weight is reduced, so that it only requires one horse to draw it. A similiar arrangement of rollers might be used for crushing or bruising roots or other substances.

NOTICES.

In consequence of a large quantity of naval matter claiming a space in this number we have been compelled to defer the publication of our next article on "Laying Off."

Several letters and papers are likewise of necessity allowed to stand over for a week.

The Mechanics' Magazine will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

Our Weekly Gossip.

The coinage of bronze one cent pieces for Canada, now nearly if not quite completed at H. M. Mint, has not, we think, obtained sufficient notice either in the scientific world or among the general public. It is in many respects remarkable, and might form a model upon which to base a new issue of money for home circulation. The artistic character of this coinage was described in our pages (and then transferred to the daily newspapers) a few weeks since, as was the composition of the metal used in it. But, as we have said, there are other points about it which call for remark. The new Canadian one cent is not only a representative of value, but of measure and weight. In value it is precisely the 100th part of the American dollar, or $\frac{1}{2}$th of the English shilling. Its weight is the 100th of a pound avoirdupois, and its diameter is exactly, mathematically, one inch, or $\frac{1}{12}$th of a foot. It is easy to see the value of these arrangements. On many occasions the coins might be used in lieu of avoirdupois weights, or as substitutes for the carpenters' rule and compasses, as well as for the circulating medium. It is perhaps the most scientifically contrived coinage, therefore, in existence. It is chaste in appearance, well engraved, and, being much harder than copper, will wear well. More praise than this could scarcely be given, but the one cent decimal piece for Canada deserves it all. Twenty tons of these unique coins have been, we believe, despatched to our flourishing colonies, Upper and Lower Canada, and it is to be wished that some arrangement might be come to for circulating in England as light, graceful, and convenient a metallic currency. Our inferior coinage of copper is heavy, ungraceful, and inconvenient; the reverse of that we have described. But we are slow in making improvements; and Lord Overstone by objecting with all the might of his authority to the introduction of the decimal system, as he has done very recently, may be said to have delayed improvement in this particular direction *sine die*. The Decimal Coinage Commission has done much to enlighten the public as to the practicability of the decimal system of weights, measures, and notation, but apparently much more remains to be done.

Mr. Henry Bradbury, of the well-known printing firm of Bradbury and Evans—a gentleman whose beautiful system of "nature printing" has charmed us all—has introduced a new method of producing printing surfaces from engraved plates. He describes it thus:—A composition is spread over an engraved plate in order to get a cast, and from such cast an electrotype plate is obtained. The composition consists of gutta percha and animal grease, or oil, or vegetable oil (by preference hard or olive oil is used). The gutta percha is combined with the grease or oil by means of heat. The composition is kneaded and washed in warm water, and then the water is completely pressed out. The composition is laid on a plate, and heat is applied to the under or back surface of the engraved plate, so that by melting the composition the whole of the engraved parts may be filled. The coating of composition thus applied is, when dry or set, to be removed, and from it an electrotype plate is to be produced, as is well understood, but in place of resorting to the ordinary means of preparing the surface of the cast taken from the engraved plate, it is prefered to wash the surface of the composition cast over with a solution of the nitrate of silver, and then to subject the same to the vapours or fumes produced from phosphorous and caustic potash.

A curious manufacture has been established in the Tyrol, namely, that of producing by mechanical means a powder of iron sufficiently fine to be used in medicine as a substitute for that obtained by the reduction of an oxide of iron by means of hydrogen. The mode of producing this powder is not published, but it is thought that it is made by very fine files. The value of this new iron powder in medicine is not yet ascertained; but it has this difference, as compared with the powder produced by means of hydrogen, that it will not burn spontaneously in air; but it will do so easily when suspended to the poles of a magnet. If the latter is plunged into the powder, and a lighted match be then applied to the powder adhering to the magnet, the iron will burn readily and brilliantly, and when the magnet is shaken the particles fall off in the form of beautiful sparks. This property is supposed to be peculiar to the Tyrol preparation.

At the last sitting of the Academy of Sciences, Paris, a letter was read from M. Christofle, the eminent silversmith, to M. Dumas, on the subject of a new alloy, which he calls aluminium-bronze. The composition of this alloy, discovered by M. St. Claire Deville, is not stated in the letter, but it is shown that its durability under continued friction is six times greater than that of common bronze; and that it may be most advantageously used for fire-arms of all descriptions. A pistol barrel was produced which had undergone numerous trials both at Paris and at the Exhibition of Dijon. M. Christofle concluded his letter by requesting the academy to give its support to an application addressed to the Minister of War for permission to cast at the applicant's own request, a piece of ordnance of any size best calculated to test the durability of this new bronze under the most trying circumstances. This alloy can be forged at a red head, and hammered like the best steel.

M. Dufour has sent in to the Academy of Science, Paris, a paper on the anatomy of a small hemipterous insect of the genus *Leptopus*, not more than four or five millimetres in length, which possesses an organisation as complete as any large vertebrated animal, comprising a nervous system, with a brain and ganglions, a vascular trachæan respiratory system, a digestive apparatus composed of a pair of salivary glands, a stomach with its pyloric valve, a chylific venticle, &c., &c. All the members of this insect are so minute and so fragile, that they defy the scalpel, pincers, or scissors; the dissection must, therefore, be effected with the point of a fine needle in a watch-glass filled with water, and it requires many specimens in order afterwards to be able to re-constitute the different fragments.

Sir Benjamin Brodie, as president of the Royal Society, received a very large party of eminent scientific and literary persons on Saturday evening, in Burlington-house. Various interesting objects were exhibited, and the fine collection of portraits belonging to the Society, which have been recently hung in the Society's meeting room, attracted much attention. Among those present were—His Royal Highness the Prince Consort, the Lord Chancellor, the Marquis of Lansdowne, Lord Campbell, Sir R. Murchison, the Chief Baron, Sir C. Lyell, Sir C. Fellows, Sir R. Vyvyan, President of the College of Physicians, Sir J. Rennie, General Sabine, Colonel Yorke, General Monteith, Professor Owen, the Master of the Mint, Dr. Webster, Professor Wheatstone, Sir E. Landseer, Sir G. Back, Mr. Babbage, Mr. Faraday, Mr. Rowland Hill, Dr. Tyndall, Mr. Yates, Mr. Brodie, Mr. Weld, Mr. Mylne, Mr. Parker, Mr. Spedding, Mr. Forster, Mr. James Dixon, Dr. Sharpey, Mr. Dilke, Mr. Brandt, Mr. Weigall, Mr. Tite, Mr. Claudet, Mr. Yorke, Mr. Pole, &c.

Captain Norton—to whose claims we have drawn attention in our leading columns—has brought out a new destructive missile, a kind of liquid-firebrand, as the *Times* military correspondent denominates it, for throwing into buildings and setting them on fire, blowing up powder magazines and ammunition waggons, and setting fire to the ships of an enemy. It is composed of a wooden tub charged with the liquid-fire. In ordinary shells the metals take no part in the conflagration, but in this new missile the shell as well as its charge becomes incendiary, and all is fire. There can be no doubt, after the success which attended the experiments made at Chatham this week with the new missile, that rifle shells charged with liquid-fire are far more efficient for blowing up ammunition waggons in the field than ordinary shells. Spherical wooden brands may be saturated with the liquid-fire, and then discharged from ordinary smooth bore cannon. On Wednesday, nearly the whole of the officers of the Royal Engineers now at head-quarters, Chatham, assembled on the practising-ground for the purpose of witnessing a trial of Captain Norton's missiles, in order that a report upon the inventions may be made to the Horse Guards by Colonel Sandham, Director of the Royal Engineer establishment. Captain Norton conducted the experiments, assisted by a sergeant of the Royal Engineers. All went off most successfully except the apparatus for submarine explosions, in which some derangement took place. At the close of the experiments Captain Norton expressed his willingness to repeat them before the officers of Engineers on another occasion.

Mr. William Chambers, of Glenormiston, one of the famed publishers of *Chambers' Journal*, &c., has just vested in the Magistrates and Town Council of Peebles, his native place, the property of an institution, to be called "The Chambers' Institution," in trust for the use of the inhabitants of the town and district. The building and fittings-up, including a public assembly hall, a museum and gallery of art, a reading room, and large library, will, it is said, cost about £30,000. The internal decoration of the building is superintended by Mr. James Ballantine, author of "Ilka blade of grass," "The wee raggit laddie," &c.

We cannot refrain from putting in a good word for the penny *London Journal* and its present managers. The last number (for April 16), now before us, merits the warmest applause. This is perfectly true of its literary features, but it is very remarkable in respect of its illustrations, every one of which is good, while some are truly beautiful specimens of the wood engraver's art. The fine views of Hampton Court deserve especial mention; but they fall short of the excellence of the opening picture of Prince John and the Jew, from Scott's Ivanhoe, drawn by Gilbert. It is no exaggeration to say that this is a magnificent picture, surpassing everything of the kind that we have seen of late. The whole number, when one remembers its price, is a marvel, containing, as it does, very nearly 180 square inches of wood engraving of a very superior kind; and all this, with a mass of good literature, for 1d.! Truly, the working classes are very well served by the press now-a-days. We may add the *London Journal* is now, we believe, what it was not a short time since, and that is—honest, for it acknowledges the sources of its information. This was not always the case. In times past we have very, very often had the pleasure—or the displeasure, which was it?—of observing our own remarks unacknowledged in its columns. We see we are credited with them now when they are quoted.

Nearly a column of the *Times* of Tuesday last was occupied by a most curious letter (paid for as an advertisement) from the rector of Barnet, the Rev. H. J. Newcome. He commences by saying the "good time" has come, for he has discovered a mode of saving three-fourths of all the fuel used in the world. For four months, with an apparatus costing £7, he has heated a church containing 200 people every Sunday to a summer temperature with less than 3d.-worth of wood. He has not submitted his apparatus to scientific men because God "does not confine his gifts" to them. He is going to make millions of money by the invention, and with them he intends first to suppress the Great Social Evil—buy it up, we presume—and, secondly, to furnish the Bishop of Newfoundland with a small steamer. After mentioning these proposals, he states that he is about to charge 10s. the first week, 5s. the second, and so on, to persons who inspect the apparatus (which is patented, he says, in all countries), and concludes by observing that he should be ashamed to sit in the House of Commons if he had first to promise how he would vote when he got there, and calls upon electors throughout the country to go individually to "the most religious—the most charitable man they know," and ask him to go to Parliament unshackled. We lately heard, if we mistake not, that the dissenting chapels of Barnet were flourishing, while the Church was in a sad state of decline. If this be so, we can readily guess the cause. We would suggest to the rev. gentleman whether he would not do well to go to a certain large edifice at Hanwell, and carry on his experiments there for the future.

It is stated that one of Boydell's traction engines, in a trial a few days since at Manchester, described a circle of 80 feet in diameter, steered clear of a crane, and was driven between gate-posts in a satisfactory manner. The engine had a train of four waggons attached. It was built by Mr. Burrell, of Thetford, Norfolk, and is to be sent to Venezuela, South America. The train has been worked between Manchester and the colliery of Messrs. Gibson, Little Halton.

M. Latry, of Greenoble, has invented, says the *Bulletin*, a singular method of making artificial wood hard, solid, heavy, susceptible of the highest polish, and of a dark colour like ebony. It is made by mixing sawdust with bullocks' blood, and then subjecting the composition to a very heavy pressure by means of the hydraulic press. With the material thus formed all kinds of furniture and ornamental work may be made—in short, it can be used for all the purposes to which hard woods are applied.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated March 1, 1859.

536. E. J. Hughes, of Chancery-lane. Improvements in preserving animal food, poultry, game, fish, fruit, and other similar substances. A communication from E. Gorges, of Paris.

Dated March 12, 1859.

634. J. Palmer, of Sutton Coldfield. Warwick, Edge Tool Maker. A new or improved trap for catching animals, birds and fishes.

Dated March 16, 1859.

650. I. Ash, of Great Bridport-st., Blandford-sq., Locksmith. Improvements in the construction of locks and latches.

664. W. Avery, of Birmingham, Engineer. Improvements in machinery for the manufacture of screws.

668. J. Clark, of Newton Heath, near Manchester. Improvements in the manufacture of fabrics in which compounds containing india rubber are used.

670. H. Bessemer, of Queen-st.-place, New Cannon-st. Improvements in the manufacture of crank axles.

Dated March 17, 1859.

672 C. Defries, of Hounsditch. Improvements in lamps.

674. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for folding and stitching sheets of paper. A communication.

678. A. G. Hutchinson, of West Derby, Lancaster, Builder. Improvements for counteracting damp in buildings.

Dated March 18, 1859.

684. W. B. Taylor, of Ballymena, Antrim, Gentleman. Certain improvements in or applicable to looms for weaving.

690. R. Mushet, of Coleford, Metallurgist. A new or improved metallic alloy.

692. A. L. Thirion, Pastor, of Asche en Refail, Belgium. Improvements in water, wind, steam, and hand mills.

694. J. W. Duncan, of St. John's-wood, and J. E. A. Gwynne, of Regent's-park, Gentleman. Improvements in, or connected with, apparatus for the generation, application, and condensation of steam, part of which apparatus or arrangements is applicable to other purposes.

Dated March 19, 1859.

696. W. B. Gingell, of Bristol, Architect. Improvements in the form of metal bars used for the stiles, rails, heads, and sills of window sashes, casements, and other lights.

698. S. Stein, of Chapel-place, Poultry. Manufacturing a resinous carton or pasteboard from vegetable matter, an improvement for roofing, ship sheathing, lining walls to prevent dampness, and other uses. A communication from A. M. Chevalier.

702. J. Howden and A. Morton, of Glasgow, Engineers. Improvements in apparatus for obtaining and regulating motive power.

704. W. and S. Pickstone, of Radcliff-bridge, near Manchester, Cotton Spinners. An improvement in stiffening, sizing, filling, or weighting textile fabrics.

706. W. C. Cambridge, of Bristol, Agricultural Implement maker. An improved construction of chain harrow.

Dated March 21, 1859.

708. A. Baucq, Sugar Manufacturer, of Marchiennes, France. Maintaining graters mechanically.

710. R. Whittaker, of Lennox Mill, Stirling, Millwright. Improvements in the manufacture or construction of metallic rollers or cylinders and mandrills for printing.

712. J. Roberts, of Staley Bridge, Engineer. Improvements in packings for pistons.

714. J. Bickerton, of Oldham, Machinist. Improvements in opening and securing window sashes.

716. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin, of Tottenham, India Rubber Manufacturers. An improved compound or preparation of materials for, and mode of covering and insulating wires or conductors used for telegraphic or electrical purposes.

Dated March 22, 1859.

718. G. P. A. Lutz, of Paris, Manufacturer. An improvement in veils.

720. P. Tagliacozzo, of Broad-st.-buildings. An improvement in metallic pens.

724. J. T. Pitman, of Gracechurch-st. Improvements in springs for railroad cars and for other purposes. A communication from J. J. Fields, of Brooklyn.

726. S. Newington, of Ridgway Ticehurst, Sussex, M.D. Improvements in apparatus for distributing seeds and manure.

728. W. P. Wilkins, of Ipswich, Engineer. Improvements in the arrangements of valves, and in their application to steam-engines.

732. J. Tyssen, of Rotterdam, Mariner. An improved apparatus for indicating the speed of ships and other vessels.

Dated March 23, 1859.

735. S. Oram, of Fleet-st. Improvements in pipes or tubes for generating and superheating steam.

736. W. Adamson, of Newcastle-on-Tyne. Improvements in apparatus for propelling vessels.

737. S. Clarke, of Albany-st., Regent's-park. Improvements in the manufacture of candles.

738. W. Middleship, of Mile-end, Officer of her Majesty's Customs. Improvements in propelling vessels.

739. J. Evans, of Nash Mills, Hertford, Paper Maker. Improvements in the manufacture of paper.

741. J. V. Hielakker, of Brussels, Civil Engineer. Improved apparatus for pressing or moulding artificial or patent fuel, fire-bricks, and similar articles.

742. G. Neal, Gas Chandelier Maker, of Birmingham. Certain improvements in apparatus or fittings connected with the burning of gas for regulating and economising its consumption.

743. W. Delany, of Norfolk-st., Strand, Gentleman. Improvements in ploughs for tilling land. A communication from L. D. Phillips, of Chicago.

744. J. H. Johnson, of Lincoln's-inn-fields. Improvements in machinery or apparatus for the manufacture of sheet tin. A communication from M. Masson, of Paris.

745. P. P. Bell, of Paris, Gentleman, and H. Reger, of Cologne, Gentleman. Improvements in steam boiler and other furnaces. A communication from A. Speich, of Strasbourg.

746. F. Tillett, of Banner-st., St. Luke's, Splint Cutter. Improvements in machinery for cutting splints for matches.

Dated March 24, 1859.

747. W. and J. Garforth, of Dukinfield, Engineers. A certain improvement in metallic pistons.

748. W. E. Wiley, of Birmingham, Pen Manufacturer. Improvements in the manufacture of boxes or cases used for holding needles, pens, matches, pencils, and for other like purposes.

749. W. E. Wiley, of Birmingham, Pen Manufacturer. New or improved instruments to be used in burning and supporting candles.

750. F. E. Sharp, of Blackheath. Improvements in machinery for corking bottles.

751. E. S. Tebbutt, of Leicester, Elastic Web Manufacturer. Improvements in the manufacture of elastic fabrics.

752. C. Sanderson, of Sheffield, Merchant. Improvements in preparing, tempering, and covering, or coating thin strips, or sheets of steel.

753. W. Clark, of Chancery-lane. A machine for separating oats from their husks or chaff. A communication from L. J. E. Dupont, of Paris.

Dated March 25, 1859.

754. H. Rigby, of Salford, Engineer. Improvements in machinery or apparatus for obtaining motive power, applicable to hoists, and all other purposes to which motive power can be applied.

755. C. Cowper, of Southampton-buildings. Improvements in telegraphic cables. A communication from R. J. Bingham, of Paris.

756. R. Baker, of Liverpool, Watch Maker. Improvements in chronometers, watches, and other time-keepers.

757. J. H. Johnson, of Lincoln's-inn-fields. Improvements in fire-arms. A communication from F. H. Bell, of Washington.

758. W. E. Newton, of Chancery-lane. Improvements in ovens for baking bread and other substances. A communication from T. Russell, of New York.

759. C. Hill, of the Chippenham Station, Great Western Railway. Improvements in the permanent way of railways.

760. H. Humphreys, sen., of Buckingham, Gentleman. An improvement in unhairing hides and skins, and in the manufacture of leather.

Dated March 26, 1859.

761. G. Haseltine, Gentleman, of Washington. Improvements in the manufacture of small metallic chains. A communication from E. H. Perry, of Rhode Island.

763. E. Steane, of Brixton, Widow. An improved means or apparatus for preventing candles dropping or guttering.

765. M. Firth, of Sheffield, Steel Manufacturer and Merchant. Improvements in machinery for grinding saws and flat plates of steel. A communication from E. T. Jones, of Montreal.

766. G. Naylor, of Stonehouse, Devon, Lieut. An apparatus for measuring and indicating the distance passed over or travelled by the same.

767. J. C. Evans and P. Soames, of East Greenwich, Engineers. Improvements in apparatus for superheating steam.

768. M. A. Muir and J. McIlwham, of Glasgow, Machinists. Improvements in moulding or shaping metals.

769. E. Dowling, of Little Queen-st., Holborn, Scale Maker. Improvements in weights.

770. B. and C. L. Smith, of Spitalfields, Manufacturing Chemists. Improvements in the preparation of certain colouring matter, applicable for dyeing and printing.

771. J. Buckley, of Horwich, Lancaster, Calico Printer, O. Greenhalgh, of the same place, Manager, and R. Hutchinson, of the same place, Mechanic. Improvements in machinery or apparatus for printing woven fabrics.

Dated March 28, 1859.

772. C. J. Richardson, of Kensington-sq. Improvements in apparatus to be applied to chimneys or flues of buildings, for preventing downdraught or return smoke, for their insuring upward ventilation, and for reducing the quantity of smoke or the blacks from the smoke passing into the atmosphere.

773. C. F. Vasserot, of Essex-st., Strand. An improved diving apparatus. A communication from P. Biggard, of Lyons.

774. J. Buckingham, of Walworth-common, Civil Engineer. Improvements in machinery or apparatus employed in drawing fibrous substances.

775. A. V. Newton, of Chancery-lane. An improved construction of furnace for reheating steel, preparatory to the hardening, tempering, or annealing process. A communication from P. G. Gardiner, of New York.

776. A. Turner, of Leicester, Elastic Web Manufacturer. Improvements in the manufacture of elastic fabrics.

777. A. V. Newton, of Chancery-lane. Improved apparatus for retaining the oil or other fluid used for annealing, tempering, and hardening steel at an equable low temperature. A communication from abroad by P. G. Gardiner, of New York.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

814. F. P. A. Auburtin, of Paris. An improved preparation of food for herbivorous animals. Dated April 1, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, April* 12, 1859.)

2707. G. Oates. Scissors. A communication.
2725. J. Luis. Rail-road. A communication.
2733. J. Colyer. Casks.
2744. H. Adcock. Annealing wire.
2745. F. Warner, J. Derbyshire, and A. Mann. Cocks.
2747. H. Bessemer. Wheels and tyres.
2748. S. Newington. Agricultural implements.
2749. A. E. Davis and R. Wright. Colouring matter.
2759. J. Baillie. Railway wheels.
2765. S. Peters. Pipes and tubes.
2771. J. Cameron. Sugar.
2772. R. Legg. Tobacco.
2794. R. A. Brooman. Gloves. A communication.
2796. E. W. Scale. Railway breaks.
2807. S. W. Pugh. Purifying oils and spirits.
2820. J. Barrow, jun. Coal gas tar.
2822. J. Eccles. Bricks, tiles, &c.
2827. T. Allen. Bedsteads.
2828. J. Wilson. Cultivating land.
2849. A. Rollason. Waterproof tissues.
2855. R. A. Brooman. Threads, &c. A communication.
2863. G. W. Baker. Manger fastening.
2864. R. A. Brooman. Transmitting telegraph signals. A communication.
2869. H. Bridges. Working breaks.
2872. A. V. Newton. Condensing. A communication.
2873. J. Bullough. Looms.
2880. R. Wilson and R. Wilson, jun. Leather.
2961. C. M. A. Marion. Case for photographic paper.
2972. W. Haworth and W. Barker. Spinning.
2977. T. Pickford. Manure.
55. G. K. Geyelin. Gas burners.
64. F. Versmann and A. Oppenheim. Rendering substances non-inflammable.
80. C. M. Kernot. Paraffine.
88. F. Versmann and A. Oppenheim. Rendering substances non-inflammable.
222. H. Owen. Stockings.
518. F. Weekes. Alcoholic products.
644. D. Joy. Hydraulic engines.
645. C. H. Hurst. Wrench or spanner.
694. J. W. Duncan and J. E. A. Gwynne. Generation of steam.
707. W. Haggett. Treating metals.
710. R. Whittaker. Printing.
716. W. Warne, J. A. Fanshawe, J. A. Jaques, and T. Galpin. Insulating wires.
737. S. Clarke. Candles.
747. W. and J. Garforth. Metallic pistons.
761. G. Haseltine. Metallic chains. A communication.
780. W. Mossman. Cutting presses.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 8, 1859.

2236. E. V. Rippingille.
2238. J. and H. Mitchell and T. England.
2240. A. Nicholls and T. Walker.
2247. F. W. Gerhard.
2256. J. Holroyd.
2257. C. F. Vasserot.
2259. J. Beattie.
2260. R. Cowen, jun.
2261. J. L. and F. L. Hancock.
2266. T. Riddell.
2270. L. Wray.
2287. L. Cowell.
2289. A. Gordon.
2294. H. Martin.
2312. J. P. Gillard.
2335. W. E. Newton.
2369. R. Bodmer.
2377. F. Fowke.
2404. C. Pooley.
2533. A. V. Newton.
2717. J. H. Johnson.
2978. H. Hutchinson.
2980. A. V. Newton.
250. H. Brecknell and J. Dyer.
355. J. Aspinall.
406. W. E. Newton.
422. J. T. Jones.

Sealed April 12, 1859.

2274. G. Beadon.
2275. J. A. Gasse.
2283. A. Benda.
2285. J. C. Ollerenshaw.
2288. C. Cowper.
2293. S. Perkes.
2295. G. Baxter.
2297. S. Diggle.
2300. R. R. Jackson.
2302. G. Davies.
2309. F. J. Coulon and S. G. Giraud.
2316. A. Dunn.
2378. J. Robb.
2385. A. V. Newton.
2750. F. Pincham.
95. J. Gibbons.
280. J. Grimond.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

814. R. Halliwell.
830. A. Morton.
842. A. Morton.
843. W. Terry.
852. W. J. Curtis.
860. G. F. Morrell.
874. J. Mash.
884. R. Richardson.
888. J. Barrans.
892. L. Kaberry and A. Horsefield.
948. J. Nasmyth and H. Minton.
973. W. P. Savage.

LIST OF SPECIFICATIONS, &c.

ceipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietor of this Magazine. Other papers are hereby warned not to produce them without acknowledgement :—

STEAM ENGINES, &c., 1928, 1937, 1969.

BOILERS AND THEIR FURNACES, 1950.

ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1948, 1971.

SHIPS AND BOATS, including their fittings, 1941, 1954, 1958.

CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1953.

FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1849, 1956.

FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1926, 1929, 1945, 1947, 1952, 1957, 1962, 1968, 1975, 1976.

BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*

LIGHTING, HEATING, AND VENTILATING, 1935, 1940, 1942, 1943, 1944

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1925, 1938, 1939, 1951, 1955, 1960, 1963, 1974.

METALS, including apparatus for their manufacture, 1927.

CHEMISTRY AND PHOTOGRAPHY. *None.*

ELECTRICAL APPARATUS, 1924, 1935, 1965, 2013.

WARFARE, 1966.

LETTER PRESS PRINTING &c. *None.*

MISCELLANEOUS, 1922, 1923, 1928, 1930, 1931, 1933, 1934, 1946, 1959, 1961, 1964, 1967, 1970. 1972, 1973.

1922. J. HINE and A. ABRAHAMS. *Improvements in book-slides or holders.* Dated Aug. 24, 1858.

This consists in the application of elastic webbing to the sliding part of the tray, whereby it has a constant tendency to contract and grip the books held in the tray or holder. *Patent abandoned.*

1923. H. WILSON. *Improvements in the mounting of band saws.* Dated August 24, 1858.

This invention was described and illustrated at page 173, No. 11, of the MECHANICS' MAGAZINE (NEW Series). *Patent completed.*

1924. J. MACINTOSH. *Improvements in insulating telegraphic wires or conductors, and in apparatus employed therein, part of which apparatus is applicable to the manufacture of tubes from india-rubber.* Dated August 24, 1858.

The present inventor patented certain grooved rollers on the 14th May, 1858, for coating telegraph conductors with india-rubber. He now places other rollers in contact with the grooved rollers, one at each of the points where the india-rubber is fed into the grooves, and on these secondary rollers are formed beads adjusted so as to fall exactly in the middle of the grooves of the principal rollers, so that they form indentations in the india-rubber suitable to receive the wire or conductor. With soft india-rubber, he mixes an equal weight of shellac ground fine, and without any solvent, by means of crushing rollers. In some cases, after having coated the wires with insulating material, he again covers them with gutta percha, or other material, with which unspun fibre is intimately mixed. Sometimes it is desired to cover conductors with insulating material, and at the same time to combine yarns with, or imbed them in, the covering. For this purpose he employs a cylinder closed at the ends, with a screw just fitting within it, mounted on a hollow axis passing through the ends of the cylinder. Through this axis the yarns and the wire or conductor to be covered pass, and the bobbins from which the yarns are drawn are mounted on a frame fixed on the end of the same axis. The cylinder has an opening in its side near the end at which the yarns enter for feeding in the gutta percha. When the axis is caused to rotate, the gutta percha is pressed out at the end of the cylinder, and passes into a small box furnished with a die, and so that the yarns become imbedded in the covering. When employing more than one coating to a conductor he causes a current of cold air to impinge on the covered wire after the first coating, so as to bring it rapidly to such a consistency that the second coating may be applied without injuring the first. *Patent completed.*

1925. J. BIGGS. *Improvements in the manufacture of caps, resembling in form the Turkish fez.* Dated August 24, 1858.

Here a cap is knitted by machinery, or by hand, to the requisite shape. The cap is then milled so as to give it a felted texture and appearance. By this means a seamless cap is formed resembling the Turkish fez. *Patent completed.*

1926. H. B. BARLOW. *Certain improvements in machinery for preparing flax, wool, and other fibrous materials.* Dated Aug. 25, 1858.

Here a heckle drum covered with card-teeth is employed, and the fibrous material is supplied to this drum through a trumpet spout or between rollers. A pair of drawing rollers is applied to draw the fibrous material over the heckle drum and through the teeth, and the upper roller is fluted, while the lower one is covered with leather. This heckle drum may be applied to the drawing head of a carding engine. *Patent abandoned.*

1927. T. HILL. *Improvements in machinery or apparatus for punching and shearing metals.* Dated Aug. 25, 1858.

These consist in a framework of two sides, so that the plates may pass between them, and also on the outside, when desired. Motion is given to a shaft carrying eccentrics or cams, which rise and fall by connecting-rods. There is a cross-bar or slide in the inside, and also slides on the out-side, to which slides the punches and shears are attached. The plates rest upon dies and cutters connected with the framework, and also upon a travelling table or dividing apparatus. *Patent completed.*

1928. J. DREDGE. *Improvements in condensers for steam engines, and in pumps for working such condensers, or for lifting water from deep mines, and for any other use to which pumps are applicable.* Dated Aug. 25, 1858.

The patentee employs cold water cisterns which are not exposed to atmospheric pressure, and he constructs them respectively in the condenser around or in connection with a chamber in which the steam is condensed in the passage from the steam cylinder of the engine. He injects cold water into condensers by certain double and fourfold acting force pumps ; and he fixes the condensers with either of the pumps in connection with the cylinder of a steam engine. *Patent completed.*

1929. R. A. BROOMAN. *Improvements in the treatment of vegetable substances in order to convert the fibrous portions thereof into pulp.* (A communication.) Dated August 25, 1858.

This consists in submitting the vegetable substances to the action of steam, which steam, before entering the vessel containing the vegetable substances, passes through a vessel containing salts of soda or carbonate of soda. During the steaming the gummy matter is allowed to escape, and, the steaming over, bleaching liquid (*eau de javelle*) is applied. Water, slightly acidulated, is then poured upon the fibres, and the fibres are finally washed in clean water. *Patent completed.*

1930. W. EVANS. *Improvements in machinery or apparatus for manufacturing saw backs.* Dated August 26, 1858.

The inventor makes use of a draw bench, and in conjunction with it a die of a peculiar formation, through which the material of which the saw back is formed, is forced to pass by being attached to the draw bench. This die is so shaped that at the side where the metal enters it is sufficiently large to admit it in the unbent state, whilst at the opposite end it is gradually contracted to the dimensions of the saw back in its complete form. *Patent abandoned.*

1931. J. H. JOHNSON. *Improvements in bellows.* (A communication.) Dated Aug. 26, 1858.

Here two levers are used, one moveable and the other stationary. At the extremity of the lower or stationary lever is attached a nozzle containing a valve which is free to open outwards. The upper lever is connected to the lower one near to this nozzle by a hinged joint, allowing of free motion in a vertical direction. The blowing apparatus consists of two discs of wood fastened to the upper and lower levers respectively. The peripheries of these discs are united by leather. The passages for the air blast are formed in the lower lever and thence lead to the nozzle. It is proposed to use flexible skins in combination with the leather. *Patent completed.*

1932. C. C. CAVALLI. *Improvements in the manufacture of starch.* Dated August 26, 1858.

This invention refers to a previous patent of the inventor, and consists in using ascetic acid or chlorhydric acid, either separately or combined with rennet, pepsine, gasterase (a substance recently discovered or prepared by the French chemist Payen), or with an infusion of the bladders of animals mixed with the required quantity of water. *Patent abandoned.*

1933. J. BLACK. *An improved mode or means of obtaining, applying, and transmitting motive power.* Dated August 26, 1858.

The patentee claims a revolving face plate or disc, with curved pathways, in which acts a roller or pulley connected to a lever, forming a mechanical motion which is applicable to various instruments or machinery, so as to effect the obtaining, applying, and transmission of motive power. The application, adaptation, and combination of the aforesaid mechanical motion or revolving face plate with curved paths, in which acts a roller or pulley connected to a lever, to and with mincing machinery, pumps, and other apparatus in which reciprocating motion is required ; and to and with printing and other machinery in which rotatory motion is required, and for moving carriages, and propelling and otherwise for transmitting and applying motive power. The application and combination of the aforesaid mechanical motion with a water-wheel and pumps as set forth, for obtaining and applying motive power. *Patent completed.*

1934. J. COATES. *Improvements in apparatus or machinery for obtaining and applying motive power.* Dated August 26, 1858.

This invention, as developed in one mode of constructing engines, consists of a framework having one solid and one hollow central pillar, carrying a working beam made hollow half its length. The hollow portion is connected to the hollow pillar by joints with glands to make the same water-tight, as is also the tubular end of the beam, being attached thereby to a tubular connecting rod affixed vertically to a horizontal cylinder, which cylinder has well-fitting and packed covers at each end, through which pass the ends of the piston, which is bored to admit a shaft carrying a fly-wheel, and on which shaft the cylinder oscillates. The central external portion of the cylinder for half its upper diameter has a water channel formed upon it, equal to and communicating with the upper tubular connecting rod, which operates alternately on the valves while the piston is performing each stroke. The piston at one or both ends may be provided with one or more waste water cocks, to discharge any water that might pass the piston. There are other arrangements which we cannot give in detail. *Patent completed.*

1935. S. N. RODIER. *Improvements in apparatus for regulating gas.* Dated August 26, 1858.

When this apparatus is to be applied to each burner, there is introduced a small chamber below or near the burner. The gas is supplied to this chamber by a pipe, the exterior of which should be largest at its upper end, and tapering downwards. At the upper part of this supply pipe there are openings for the gas to pass through. The supply pipe is a light hollow cap, the interior of which corresponds in form with the exterior of the supply pipe, but so much larger in diameter as to admit of the gas flowing freely down between the interior of the cap and the exterior of the supply pipe when the cap is resting on the top of the supply pipe. The lower part of the cap is so formed that when lifted by the pressure of the gas the lower edge of the cap comes nearer and nearer as the cap is more and more lifted to the supply pipe, and thus reduces the size of the passage or space which is between the interior of the cap and the exterior of the supply pipe. *Patent completed.*

1936. G. M. SAUTTER. *Improvements in telegraphs.* (A communication.) Dated August 26, 1858.

Here a wire is employed which passes over pulleys from one place to another, and to each end of the wire a weight is attached which slides in a slot in a vertical fixed plate. On one side of the slot in each plate are marked the letters of the alphabet and figures, and on the other side of the slot a number of phrases most likely to be required. To each weight two pointers are attached, one of which points to the letters and figures, and the other to the phrases. The letters and phrases on one plate are marked in the inverse order to those on the other plate, and the length of the wire is adjusted so that when one pointer points to a letter or phrase on one plate the other pointer points to the same letter or phrase on the other plate. *Patent abandoned.*

1937. D. GRAHAM-HOPE. *Improvement of locomotive and other steam engines.* Dated August 27, 1858.

The bearing springs of a locomotive are composed of a series of steel plates piled upon each other, and are held together by a pin passing through the centre of each plate. Now, the present invention consists in raising on the under side of each plate a cup-shaped projection, which is punched or forced out of the body of the plate. The invention also relates to pistons, and consists in a solid wrought or cast iron body, which may or may not be formed solid with the piston rod. In a groove turned into this body he places a single packing ring, split into two separate parts, which he keeps open as the ring wears, by two V-pieces, which alone are acted upon by the steam pressure within the cylinder. *Patent abandoned.*

1938. T. TROTMAN. *Improvements in hair pins.* Dated August 27, 1858.

This consists in corrugating or undulating the limbs of those articles so that the corrugations are in a direction at right angles or nearly so to the plane of the two limbs of the pins. *Patent completed.*

1939. J. ELLISDON. *Improvements applicable to reading chairs and other articles used to sit or recline upon.* Dated August 27, 1858.

This consists in applying a reading desk, or a writing desk, or both, to easy chairs, sofas, couches, the arms of railway carriages, &c., in such a way that when not in use they can be folded up and stowed away out of sight. *Patent completed.*

1940. F. MATLEY. *Certain improvements in apparatus for regulating the flow of gas, and for improving its illuminating power.* Dated August 27, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

1941. W. S. CLARK. *Improvements in reefing or furling sails from the deck of vessels.* (A communication.) Dated August 27, 1858.

Here no extra weight or additional spar is requisite, as the sail is rolled around the usual spar employed in the common rig, while the studding sail booms are made to subserve the additional purpose of a chafing bar in protecting the reefed sail from chafe on the shrouds. The invention is not described in detail from the drawings. *Patent abandoned.*

1942. W. ESSON. *Improvements in wet gas meters.* Dated August 27, 1858.

Here the upper part of the meter has an air-tight water-supply tank, which communicates with the measuring chamber by a feed or supply pipe so disposed as to be always sealed. The supply tank has an air pipe, the lower mouth or orifice of which coincides with the proper water level, and a float is contained therein connected with the ordinary gas valve for shutting off the gas when the tank is empty, or the water therein too low. The water is supplied to the tank by a supply pipe which is kept sealed. When the water in the meter descends below its proper level, by reason of evaporation or other loss, it leaves exposed the lower orifice of the air pipe, and allows the gas to ascend therethrough, and the water in the upper tank to descend through a pipe until the air pipe is sealed again by the water in the meter regaining its proper level. *atent completed.*

1943. H. W. HART. *Improvements in the application of gas to chandeliers.* Dated August 27, 1858.

This relates to an arrangement of parts by which the hydraulic joint of the ordinary hydraulic double or treble tube telescop chandeliers may be dispensed with, as also the stuffing-box joint of the ordinary double tube dry telescopic gas pendants or chandeliers, by substituting parts arranged according to this invention, which is simple, and whereby all liability to leakage is prevented. It consists in connecting the upper tube or service by a flexible pipe with the body of the chandelier. *Patent completed.*

1944. F. J. EVANS. *An improvement applicable to gas purifying.* Dated August 27, 1858.

The patentee takes turnings, borings, and filings of iron, or scrap, or small pieces of iron, in the form of shot, for example, and exposes the same to gases or liquids, either at ordinary or elevated temperatures that will ensure their

Digitized by Google

rapid oxidation. When the surfaces of the pieces of metal are completely coated with oxide or rust, the metal thus oxidised is ready for use in the dry gas purifiers, where it is to be employed in the manner usually practised when purifying gas with the oxides. *Patent completed.*

1945. A. V. NEWTON. *Improved machinery for sorting silk or other thread, according to its size or thickness.* (A communication.) Dated August 27, 1858.

This relates to means whereby threads of silk, &c., are so directed on to a bobbin that it will be distributed upon different parts of the said bobbin according to its size or thickness. It also relates to means of controlling the winding of the threads on a series of bobbins or spools from the main bobbin or winding apparatus, on the several parts of which it has been distributed according to its size or thickness, so that all of one thickness will be wound upon one bobbin or spool. *Patent completed.*

1946. W. E. NEWTON. *Improvements applicable to vessels employed in the manufacture of glass, or the melting of citreous.* Dated August 27, 1858.

This consists in running off the fused materials through an orifice at the lower part of the oven, pot, or vessel. The inventor closes these orifices by stoppers made of earthy materials, or by metallic stoppers. *Patent completed.*

1947. W. KEMPE. *Improvements in apparatus used for winding woollen and other fabrics on rollers, in order to such fabrics being boiled or faced when on the rollers.* Dated August 27, 1858.

This consists partly in applying apparatus for holding and for giving motion to a roller at each of its ends. By these means the ends of a roller, when having a fabric wound thereon, will be held at each of its ends by suitable friction, or holding surfaces or instruments, which instruments will have power applied in order simultaneously to give rotary motion to them and to the roller held by them. And part of the invention consists in driving at one end only of a roller by applying friction surfaces at both ends, and applying the driving power at one end only. *Patent completed.*

1948. J. FOWLER, jun., and R. BURTON. *Improvements in the construction and arrangement of locomotive and other carriages, to facilitate their movement on common roads, and other surfaces.* Dated August 27, 1858.

Here the axle or axles of the carriage is or are supported at the ends by frames, and these frames are supported on wheels which run upon rails laid by the carriage in its progress. *Patent completed.*

1949. R. KNIGHT. *Improvements in apparatus for aerating liquids.* Dated August 27, 1858.

The lower vessel of the two which the patentee employs in an apparatus previously patented by him is made in two parts of tin, and soldered together, there being an inclined shelf formed on the interior which (excepting near the front) forms a partition which divides the vessel into two compartments, there being an opening near the front between the two compartments. In the lower vessel there are two openings, which are, when in use, closed by screw plugs, and it is by these two openings when the apparatus is placed in a horizontal position that the materials for producing the gas are introduced. Both the vessels should have spherical ends. *Patent completed.*

1950. J. IRELAND. *Improvements in cupola furnaces.* Dated August 28, 1858.

The patentee applies to blast furnaces one or more air-pipes or tuyeres, placed above the ordinary tuyeres, for bringing the metal into a fused state in a higher part of the furnace than it is by the use of the ordinary tuyeres alone, thereby melting the metal with less fuel, and also purifying it as it falls to the lower ordinary tuyeres. *Patent completed.*

1951. G. WHITE. *Ambulatory furniture for apartments.* (A communication.) Dated Aug. 28, 1858.

This consists of certain arrangements of furniture, allowing of being taken to pieces, and flapped or slid together, so as to be considerably reduced in bulk, for permitting them to be easily removed from one place to another, thereby dispensing with any particular package, and so as to form what is called an ambulatory furnished apartment. The arrangements are not described apart from the drawings. *Patent completed.*

1952. W. FOSTER. *Improvements in the manufacture or production of fabrics known as fancy moreens.* Dated Aug. 28, 1858.

This consists in combining cotton or alpaca with the worsted whilst spinning. The fabric may be then woven in the usual way, and dyed in the piece, after which it will be found that the cotton or alpaca, not taking the same colour as the worsted, the fabric will present a peculiar mottled or spotted appearance. *Patent abandoned.*

1953. G. CODDE. *Improvements in the adjustment of hose in machines for distributing liquid manure and other liquids over land, also for an improved method of, and apparatus for, manufacturing the hose to be used with such machines or otherwise, and for gathering and puckering canvas, linen, leather, and other textile and membranous substances.* Dated Aug. 28, 1858.

This relates to a method of uniting the coiled hose (described in a previous patent granted to the patentee), and consists mainly in uniting the hose by means of a bayonet joint, whereby two or more boxes and reels can be used alternately, and in succession, with the same distributor. *Patent abandoned.*

1954. J. D. BRABAZON. *Improvements in giving motion by sails to screw and other propellers of ships and vessels.* Dated Aug. 28, 1858.

Here a shaft or axis is used, running fore and aft the ship; this shaft is supported in bearings above the deck. To a boss on the shaft are applied a series of radial arms, according to the largest number of sails used. To each of these arms a sail may be applied. Each sail is kept extended when in use by a spar, and by cords and tackle such sails are kept more or less inclined, to suit the direction of the wind. The shaft gives motion to the propeller by a chain and chain wheels, or by an upright shaft. *Patent completed.*

1955. G. WEBDON and D. W. RICH. *An improved knife and fork cleaning machine, part of which is applicable to other purposes.* Dated Aug. 28, 1858.

This consists in keeping the knives flat on the cleaning board by a lever, the front end of which projects. This lever is T shaped, and has a tongue at each end of the cross piece, one tongue advancing as the other recedes. By putting the lever from the left or right, the cross piece comes down upon the knife handles and keeps the blades flat on the board. *Patent completed.*

1956. F. BRIGNOLES. *Improvements in apparatus for the disinfection and rectification of bad-tasted alcohols, by the separation of the essential oils from the alcoholic exhalations.* (A communication.) Dated Aug. 30, 1858.

This operation is accomplished by condensing the alcoholic exhalations at different degrees of temperature and in separate tubes surrounded by water, the temperature of each being marked by degrees. *Patent abandoned.*

1957. J. PLATT and E. HARTLEY. *Improvements in certain parts of machinery for preparing and spinning cotton and other fibrous materials.* Dated Aug. 30, 1858.

This relates to the top rollers of drawing rollers, and consists in making use of loose bushes fitted on a parallel spindle, which spindle has a collar at one end, and a loose nut or bush at the other. The bushes, collar, and nut support the bosses, which are covered with flannel and leather, and prevent them moving laterally. *Patent abandoned.*

1958. E. MASSEY. *Improvements in ships' logs.* Dated Aug. 30, 1858.

This consists, 1, in prolonging the body or case containing the train of wheels, so as to enclose within it the universal joint by which the rotator is connected; 2. In the method of fixing the cord of the rotator to the tail-piece of the universal joint; and, 3, In the use of a thumb screw to securing the guard plate which retains the ring of the rope by which the log is dragged. *Patent completed.*

1959. J. BRAZIL and J. MCKINNELL. *An improved method of indigo blue dyeing.* (A communication.) Dated August 30, 1858.

This consists in dipping two pieces of fabric (placed back to back) into the dyeing liquid, so that the two back surfaces of the cloth may be in close contact, and unexposed to the atmosphere, allowing only the two outside or face surfaces to be exposed to the oxygen of the atmosphere, which causes the outer or face surfaces to absorb a greater quantity of indigo or dye than the back or inner surfaces by which the face sides of the cloth will present a dark blue, and the back sides a light blue colour. *Patent completed.*

1960. G. DAVIES. *Improvements in billiard tables and cues.* Dated August 30, 1858.

Here the frame of the table is of an annular form and has three or more legs. The inner part of the frame has three or more vertical grooves, in each of which slides on mountings a small pulley or wheel, capable of being raised or lowered by an adjusting screw. Upon these pulleys or wheels rests the top of the table. To the centre of the table underneath is fixed a rod or pin which slides in a hole formed in a transverse piece attached to the annular frame. This rod or pin serves to centre the table, and to maintain it in its position on the pulleys or wheels. To adjust this table it is merely necessary to raise or lower the several wheels by three screws, according to the indications of a spirit level which is let into the frame. The cues are made of a rod sliding in a tube, and projected forwards by a spring. The rod is forced inwards, compressing the spring and is held by a catch. The cue being placed and held firm opposite the ball, the catch is released by the finger, and the rod being projected forwards by the spring strikes the ball. *Patent completed.*

1961. J. BRAZIL and J. MCKINNELL. *An improved method of indigo blue dyeing.* Dated August 30, 1858.

This consists in printing or covering the face side of the fabric with certain chemical substances to draw the indigo in the dye not more to the face side than to the back of the fabric, so that when finished the face side shall present a dark blue and the back a light blue colour. The patentees employ a salt of manganese, preferring the sulphate or muriate of manganese. *Patent completed.*

1962. B. HANSON, *Improvements in means and apparatus for sizing and drying woollen yarns or warps* Dated August 30, 1858.

This consists in the use of a series of tiers of heated pipes so arranged that woollen yarns can be traversed at a suitable distance from them betwixt pairs of rollers which keep them steady and detached or separate from each other. Also in the use of fans for producing a current of air which is heated in passing the hot pipes or hot surfaces. *Patent abandoned.*

1963. J. OXLEY. *Improvements in baths.* Dated August 30, 1858.

This consists in constructing a bath somewhat in the form of the ordinary hip bath, and fitting the same with a moveable seat containing a recess for receiving a moveable tray, pool or bidet, or the pool or bidet may be formed in such moveable seat, and of any convenient form, with a plug for permitting the escape of the water. *Patent completed.*

1964. G. JONES. *Securing joints in slate ridge roll.* Dated August 30, 1858.

Here the patentee fastens under the flange at the joint of ridge a piece of metal in a separate piece under one flange, or in a piece of sufficient length to cross the breadth of the two flanges, and connects them together. Upon the upper angle of ridge is laid a roll, the ends of which he connects together by inserting in a slot a tongue of metal laid in oil cement. The ends of the said roll break joint with or overlap the joint in the ridge. *Patent completed.*

1965. J. L. CLARK, F. BRAITHWAITE, and G. E. PREECE. *Improvements in telegraph cables.* Dated August 30, 1858.

This refers to a patent granted to Josiah Latimer Clark, 20th Dec., 1853, for the use of asphalte &c., around electric telegraph wires, and consists, in more effectually applying and supporting the said non-inductive coating. The wire or wires already insulated with gutta percha, &c., are covered with a coating of hemp which has been highly dessiccated and deprived of all moisture, and then saturated with a hot mixture of turpentine, rosin, pitch, tar, asphalte, oil, &c., such saturation being completed by passing the said materials through air-tight vessels, from which the air is exhausted before the admission of the non-conducting mixture, and into which the air or the mixture can afterwards be injected under pressure. The insulated wires are surrounded with this mixture of fibrous material, which may either be laid on in a mass or strands coiled around the wires. The cable thus formed is again saturated with the mixture. It consists, 2, in preserving cables from decay, by surrounding the wires with a compound of pitch, tar, asphalte, &c., retained upon the cable by strands or flat bands of hemp saturated with the above mentioned mixture and plaited or braided round the cable. It consists, 3, in preserving iron cables from decay by intermingling among them wires of zinc. It consists, 4, of methods of joining the iron wires and the conducting wires of submarine and other telegraphs. The patentees form a right-handed thread or screw on the end of one of the wires, and a left-handed thread on the end of the other wire to be united to it; the two ends are then inserted in a screw ferrule or collar, cut with corresponding right and left threads, and by screwing it up the two ends are drawn into contact and form a secure joint. It consists, 5, in forming the conducting wires of submarine cables by building up a solid conducting wire in segments so that any defect or breakage in a single segment will not endanger the continuity of the whole cable. *Patent completed.*

1966. E. LINDNER. *Improvements in breech-loading fire-arms and ordnance, and in cartridges.* Dated Aug. 30, 1858.

This consists in constructing breech-loading arms so that the breech is closed in one case by turning the barrel, and in the other by turning a nut or screwed collar upon the barrel. *Patent completed.*

1967. L. WIART. *An improved mode of generating steam, or heating water or liquids.* Dated August 30, 1858.

This consists in the introduction into boilers, steam generators, or evaporating vessels of strips, bands, or frames, made of thin copper, and which strips, bands, or frames, when suitably adapted and arranged, will conduct and transmit the heat to the water or other liquid, and will thereby greatly facilitate the generation of the steam or heating of the water or liquids. *Patent completed.*

1968. T. R. HARDING. *Improvements in the method of making straight or circular combs for flax, wool, or silk machinery.* Dated August 30, 1858.

This consists, 1, in using a description of morticing head, or the drilling spindle and the head itself, connected with the dividing head or other dividing apparatus, so that the morticing tool shall exactly coincide with the holes previously made by the drill and the dividing head, so that by pressure the holes may be formed of the shape of the pins, which may be flat or otherwise. 2, In driving such pins into circular or other combs so that the combs shall retain their primitive shape. *Patent abandoned.*

1969. J. H. JOHNSON. *Improvements in the construction of governors or regulators for steam engines.* (A communication.) Dated August 30, 1858.

This relates to rendering the action of the governor more sudden, sensitive, and powerful than that of the ordinary description, whilst the governor itself will work equally well in a horizontal, vertical, or oblique position. *Patent completed.*

1970. E. SPARY. *Improvements in fumigators.* Dated August 31, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1971. M. A. F. MENNONS. *Improvements in the supports of rails for railways.* (A communication.) Dated Aug., 31, 1858.

A complete specification of this invention was filed with the application, and an abridgment of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE (Old Series). *Patent completed.*

1972. M. A. F. MENNONS. *Improvements in apparatus for the elevation of liquids.* (A communication.) Dated August 31, 1858.

A continuous flow of liquid to any desired elevation is here obtained by the superposition of any required number of syphons. *Patent abandoned.*

1973. M. A. F. MENNONS. *An improved apparatus for mounting the driving bands of machinery in movement.* Dated August 31, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1974. F. AYCKBOURN. *Improvements in the construction of beds and other articles for sitting or reclining upon.* Dated August 31, 1858.

The inventor divides the case into numerous independent cells, each closed at one end and open at the other, having one long flap, which covers all the orifices, and is to be secured underneath. He places in each cell a long bag made of india-rubber, &c., for holding water or air, furnished with a mouth-piece, the dimensions of which bag exceed that of the cell by about one-fifth, which prevents the bag bursting. *Patent abandoned.*

1975. J. STONEHAM. *Improvements in cleaning and treating cotton and woollen waste or other fibrous materials, and in extracting oils or grease therefrom.* Dated August 31, 1858.

Here the waste is sorted, and placed in vessels containing water. The waste is then drained and put into any spirituous liquid, such as naptha, benzole, benzine, oil of turpentine, &c. After this the spirit and grease are pressed out of the waste, and the latter placed in a wash-wheel and afterwards wrung and dried in stoves. *Patent abandoned.*

1976. D. and J. HEYWORTH. *Certain improvements in looms for weaving.* Dated August 31, 1858.

This consists, 1, of certain means of preventing the shuttle from "flying out." 2. In breaking the force of the blow of the picker when it has discharged the shuttle. 3. In preventing the rebound of the shuttle. 4. In preventing the bottom shafts of the healds from coming in contact with each other. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, APRIL 22, 1859.

THE GOVERNMENT CONE TELEGRAPH SYSTEM.

The Government have lately secured to themselves the use of an improved system of telegraph signalling patented by Mr. Redl, and have introduced it both in the Royal Navy and in the War Departments. It is known as "Redl's Cone Telegraph" system, and is so well and simply devised that it will doubtless prove of very great benefit to the services. We will not mention the sum which the Admiralty paid for it; we will only say they got it for very little. On another page of this Number we have given a very full illustrated description of it, and with the view of attracting to it the attention of persons interested in our mercantile navy, we propose to say a few words in reference to it here.

Instead of the various and numerous flags hitherto used on board ship for telegraphic signalling, Mr. Redl employs simply a set of collapsible cones, which may be expanded separately or together as may be desired. They are formed in pairs, base to base; they are closed by india-rubber springs, and expanded by the pulling of a line or cord. The *notation* of the old flag system only is done away with; the *code* remains unaltered.

The new system has many advantages. For example, a flag cannot be seen except it is "spread" by the wind, and in wet, still weather it is often most difficult to spread them; but the cones are expanded with certainty in an instant. Again, when a flag is spread its colour has to be detected; but the colour of the cones has nothing to do with their signalling. Again, atmospheric conditions often interfere seriously with the "reading" of flags; but from these the cone signals suffer but little, if at all. In evidence before a committee of officers, Captain Jermingham, R.N., said:—"A signal was flying three hours from the Victory in Portsmouth Harbour to the Bellisle at St. Helen's, in consequence of easterly mirage, during which time a constant communication was being kept up with the 'cones' from the Blenheim in Portsmouth Harbour to a cutter at Calshott Castle; three conspicuous flags were hoisted in the cutter, which were not seen on board the Blenheim, nor the circumstance known till the next day." Again, the Redl system admits of greater rapidity in working than the flag system—a point of immense importance under some circumstances. And, yet again, while the new system admits of more numerous combinations than the old, it is also learnt with greater ease. On this last point, Captain Egerton, R.N., stated:—"A boy belonging to H.M.S. Neptune, aged sixteen, learnt the cone system under my instruction in a week; he had been for six months under the signalman of the Neptune learning the naval signals; but by the signalman's account he did not know them one-half as well as he did the cones after his week's instruction under me." In respect of cost, *twenty-five* sets of cones may be purchased at the price of *one* set of flags! If we compare the cone telegraph with the semaphore telegraph used for naval and military purposes on shore, we shall find the new system has the advantage in that comparison likewise. Thus both on land and by sea the new system proves itself best. It may, therefore, be used in both cases with benefit, and with the further advantage of rendering the one telegraph system common to the army and navy, and of thus facilitating the co-operation of the two services.

We have but hastily and imperfectly sketched the merits of Mr. Redl's invention; but we have said sufficient, we hope, to urge the reader to acquaint himself with it more closely. The Admiralty, as we have said, have, after some years' of hesitation, adopted it. We hope the merchant service will not delay the use of it. On this head we will content ourselves with repeating what the *Daily News* said a short time since, viz.:—"Every mercantile sailor should be as able to read the cones or interpret the dual system, as he is able to box his compass. Then, either with or without a code, either with or without a set of cones, two ships when in sight or hearing could communicate any message whatever to one another. It is impossible to exaggerate the value of such a system to the mercantile marine. The Trinity-house should see to this; our shipowners should bestir themselves. No ship should put to sea without a set of cones, nor any captain be allowed to navigate her who cannot use them."

THE WAGES OF MECHANICS IN H.M. DOCKYARDS.

Considerable dissatisfaction having lately been expressed by the mechanics employed in H.M. Dockyards, in consequence of what they deem the injustice of the present system of regulating their wages, a few explanatory statements upon the subject will be of value just now.

The value of the work performed by the mechanics of the Government Dockyards is now estimated according to a scale of prices upon the compilation of which great care has been bestowed, and the week's work of every gang of men is required to reach a fixed amount. But while the men are mulcted if their labour falls short of the standard, they receive no extra pay, however much the standard may be exceeded. This is the ground of their dissatisfaction: and, viewed superficially, it certainly seems a very unfair arrangement. But if examined more closely it appears less objectionable. For, the standard amount of labour demanded is not, of course, an absolute quantity; nor was the scale of prices by which the wages are adjusted framed according to the intrinsic worth of particular pieces of work. Mechanical operations have, of course, no fixed absolute value. A scale of prices has been fixed, giving to each "job" such a value that when the men are allowed to earn unlimited wages their earning shall fall somewhat short of those of men working similarly in private dockyards. The Admiralty, therefore, virtually say to the men (shipwrights, for instance), "When you exert yourselves to the utmost, you are able to earn six or seven shillings per day in the usual working hours under a given scale; and in order that you may at all times exert yourselves moderately we require you to earn at least 4s. 6d. per day under the same scale. You cannot earn less without idling, and we shall mulct you if you do."

Now, the Admiralty are unquestionably at perfect liberty to hire labour on these terms if they please, and that without any show of injustice. But labour can only be estimated by averages; and it is manifestly essential to the fair operation of such a system that the period over which the average extends shall be sufficiently long to allow the necessary imperfections of the price-list to balance each other. The period now selected is a week, which is much too short. We believe a month should, in fairness to the men, be fixed upon. Until this is done, a sense of injustice will exist.

The remedy which a correspondent of the *Times* lately suggested for the supposed evil is a very curious one—"a second superintendent in each of our dockyards." Another superintendent naval officer to keep mechanics and mechanical officers moving on! This gentleman knows but very little of the internal working of our dockyards. A superintendent naval officer in "his office" may be, and often is, a very useful functionary; but a superintendent naval officer "constantly on the alert, visiting the different works, building slips," &c., has often proved one of the greatest evils that ever operated against the public interest in our dockyards.

THE CORT CASE.

A few weeks since we drew attention to the condition and claims of the Cort family. Since that time a memorial has been addressed to the Prime Minister on their behalf, bearing the signatures of a very large number of the most influential engineers, manufacturers, and commercial men in the kingdom. This is gratifying; but we fear the political activity and anxiety of the members of the Government will be so absorbing for the next few weeks that they will make no opportunity for doing the justice that is due to the surviving son and daughters of Henry Cort. Something should, therefore, be done without delay to meet the immediate necessities of the case; and we have hope that something will be done. The son, Mr. Richard Cort, has been invited, we understand, to the ensuing meeting of the South Wales Institute of Engineers, at a former meeting of which he was received with much generosity and kindness. Of this Institution Mr. Ebenezer Rogers is the highly-respected president, and as he is supported by a band of gentlemen who have, we believe, both the knowledge necessary to a just appreciation of the case, and the liberality to act upon that knowledge, we doubt not they will inaugurate some moderate but useful plan of present relief. Once begun by them, the system would be imitated by other societies, and much good would be effected. The men of South Wales are the fittest to lead in this matter. None understand the iron manufacture better than they, and therefore none are better acquainted than they with the merit of Cort's inventions. We will only add two suggestions. We think there are two classes who might do good service in this movement. We allude, first, to the few chief iron-masters—three or four firms which we need not particularize—who, in the nature of things, must have benefited most largely by the labours and losses of Cort; they might each contribute some handsome sum to the fund. We allude, secondly, to the working iron-makers—puddlers and others. What could possibly be more fitting or more honourable in them than a general "penny subscription" on behalf of the Cort family? If the working men will take up this suggestion, they will experience no difficulty in giving it effect.

THE ARMSTONG GUN.

We this week propose to bring together a mass of information respecting the Armstrong gun, according to the announcement made in our last number. We will commence with the following highly-important paper which was communicated by Captain Younghusband, R.A., F.R.S., to the Royal Artillery Institution in 1856. There can be no doubt as to the perfect authenticity and accuracy of the following description of the Armstrong gun as then made:—

* Mr. Armstrong was authorised by the Duke of Newcastle to construct one or more guns not exceeding six in number, on the plan he had suggested in an interview with his Grace, and to make the necessary experiments in connection with the subject, at the Government expense. Mr. Armstrong, acting upon this authority, has confined himself, up to the

Digitized by Google

present time, in the production of a single gun; to make that one gun a test, not only of the principle he had recommended, but also of the feasibility of loading a field-piece at the breech; and likewise of applying certain mechanical arrangements to counteract recoil, and facilitate the laying and pointing. Careful consideration was first given to the tensile strength of the various materials suitable for the construction of a gun, and some experiments were made on the strength of cylinders of wrought iron, forged in the requisite form, and afterwards bored; the result of these experiments showed great uncertainty in the strength of the material, rendering it impossible to define the thickness necessary to resist a given charge of powder. Mr. Armstrong then decided upon, and ultimately completed a gun of which the following is a description:—A core, or internal lining for the gun, was formed of cast steel, to which the requisite strength was given by encircling it with twisted cylinders of wrought-iron, made in a similar manner to gun barrels, and tightly contracted upon the steel core by the usual process of cooling after previous expansion by heat; the parts are then in that state of initial tension which is necessary to bring their entire strength into operation. Considerable difficulties were encountered in carrying this plan into practice. The arrangement for loading at the breech consists of a powerful screw having a hole through the centre in the prolonged line of the bore, through which hole the bullet and charge are delivered into the gun. A 'breech piece,' with a mitred face fitting a similar face at the end of the bore is dropped into a recess, and by the action of the screw pressed tightly into its seat, so as effectually to close the bore. The fitting surfaces which close the bore were at first made of unhardened steel—this failed; hardened steel was next used, but this yielded to the action of the powder more rapidly than before; copper was then tried, and no further difficulty was experienced. The breech piece contains the vent. The bore of the gun which was made, is 1¾ inches in diameter, and contains 8 spiral grooves, having an inclination of one turn in 12 feet; these grooves terminate at a distance of 14 inches from the breech, and the bore then gradually expands in a length of 3 inches, from 1¾ inches to 1⅞ths in diameter. The bullet, in the process of loading, passes freely through the widened space; but its diameter being a little in excess of the bore, it lodges in the tapered contraction of the commencement of the grooves. The weight of the gun by itself is about 5 cwt., including the carriage the weight is about 15 cwt., which is nearly identical with that of the light six-pounder brass gun and carriage of the service. The weight of the projectile (composed of lead, hardened with antimony and tin), is three pounds. A long course of experiments was made to determine upon the best form of bullet; numerous forms were tried, and Mr. Armstrong was of opinion that experiments required to be still prolonged, in order to arrive at the greatest attainable perfection. The form last used was a cylinder pointed in front, with a conical end behind. The charge was 14 ounces of fine blasting powder. There is an ingenious arrangement by which the recoil is absorbed, and another by which the pointing and elevating is expeditiously and correctly performed. Mr. Armstrong considers that rifled guns of this construction will be especially valuable as guns of position, where a long range is required, and proposes them as *adjuncts to*, and not *substitutes for*, the present description of field ordnance. The objects he believes to have attained are strength, durability, long range, and accuracy. Respecting the construction of heavy ordnance by the process of twisting wrought iron bars into cylinders, and combining them in the manner described, he believes no difficulty would be experienced if proper apparatus were provided for the purpose; but he does not recommend the breech-loading principle to be applied in such cases, because, in heavy ordnance, the moveable parts would be too cumbrous to be conveniently handled. The gun described above was brought to Woolwich to be inspected, and was then sent to Shoeburyness for experiment. Mr. Armstrong stated that 800 rounds had already been fired from it. At Shoeburyness 100 rounds were fired at elevations varying from ¼° to 7°. A very long range was obtained; though it was not always uniform, the direction was extremely accurate. The shot did not proceed point foremost after the first graze. All the shots that were recovered showed marks of their having completely taken the rifle grooves. A considerable escape of gas took place at the breech; the gun was loaded with great facility, and pointed quickly and accurately; the recoil was checked, but not entirely absorbed by the action of the slide on which the gun is mounted. After the completion of these experiments, Mr. Armstrong, believing the gun to be stronger than necessary, suggested its being returned to him to have it re-bored for a heavier projectile, and also to make some alteration in the rifling, by which he expected to obtain increased accuracy of fire. The gun was accordingly sent back to Newcastle."

The next authentic paper which we have to publish, or more properly to re-publish, is the following letter which was addressed by Sir William Armstrong himself to the *Times*, before he emerged into the sunshine from that "cold shade" in which so many excellent men and able inventors still lie. There cannot, of course, be any doubt about the correctness of so much of the description of Sir William's improvements as is here given:—

"Sir,—In the latter part of 1854 I submitted to the Duke of Newcastle, then Minister at War, a proposal for a gun which I anticipated would possess great superiority over the common forms of light artillery, and I undertook, with his Grace's authority, to construct a field-piece in conformity with the plan I had suggested. The gun was accordingly soon afterwards made, and has since, during a period of nearly two years, been the subject of numerous experiments, partly upon the Ordnance firing ground at Shoeburyness, but principally under my own direction in this neighbourhood. I have hitherto avoided publicity in reference to these experiments; but, as matured results of much interest and importance have now been arrived at, and as other names are already before the public in connection with gun experiments made during the same period, I feel that I may now, without impropriety, give some information on the subject. With a view to strength and durability the gun is composed internally of steel and externally of wrought iron, applied in a twisted or spiral form, as in a musket or fowling-piece. The bore is nearly two inches in diameter, and is rifled. The projectile is a pointed cylinder 6½ inches long, and its weight is five pounds. It is made of cast-iron coated with lead, and is fired from the gun with a charge of 10 ounces of powder; it contains a small cavity in the centre, and may be used either as a shot or a shell. When applied as a shell the cavity is filled with powder, and a detonating fuze is inserted in front, so as to fire the powder in the centre on striking an object. When used as a shot the powder is omitted, and an iron point, which favours penetration, is substituted for the fuze. The gun is constructed to load at the breech, the object being not only to obviate the disadvantages of sponging and loading from the front, but also to allow the projectile to be larger in diameter than would enter at the muzzle, and thus to ensure its taking the impress of the grooves and completely filling the bore. The piece weighs five cwt., and is mounted upon a carriage which bears a general resemblance to that of an ordinary 6-pounder field gun, but which embraces a pivot-frame and recoil slide. A screw is also applied, not only for elevating and depressing the gun, but also for moving it horizontally, by which means great delicacy of aim is effected. The recoil slide has an upward inclination, which enables the gun, after running back, to recover its position by gravity; and its use is to relieve the pivot-frame and adjusting screws from injurious concussion. I shall now give some particulars of the experiments recently made with this gun on the coast of Northumberland, near the village of Whitley, under the official inspection of Colonel Wilmot. Fourteen shots were, in the first instance, fired from a distance of 1,500 yards at a timber butt 5 feet wide and 7½ feet high. Six of these were expended in finding the elevation proper for the distance, but after that was determined every succeeding shot hit the object without previous graze. The final elevation of the gun was 4° 26′, and the mean lateral distance of the shot marks, from a vertical line through the centre of the butt, was only 11½ inches. Persons who are conversant with artillery practice will be able to appreciate the accuracy of this firing; but for the information of those who are unacquainted with the subject, I may state that the ordinary 6-pounder field-piece, which, in point of weight, forms the nearest approach to the present gun, is perfectly useless at a distance of 1,500 yards, and is very uncertain even at 1,000 yards. It is only, therefore, with heavy artillery that a comparison can be drawn, and it will be sufficient to state that in tabulating the practice made with such ordnance, the deflections are invariably recorded in yards, whereas with this rifled gun they can only be properly given in inches. With respect to penetration, the following particulars will be regarded as equally remarkable, considering the small weight of the shot and the length of the range. The butt was three feet thick, and composed of six layers of rock elm bolted together, so as to form a solid block. One shot passed entirely through; another struck near the edge and glanced; and the remaining six penetrated within a few inches of the opposite side. Shell firing was next tried, at a distance of 1,500 yards, the gun being fired at the same elevation and with the same charge as in previous practice at the butt. In this case, two targets were erected, one behind the other, so as to appear as one object when viewed from the gun, and a space of 30 feet was left between them. The front target was intended to exhibit the perforations of the shells before bursting, and the back one to show the effects of the fragments resulting from explosion. After some preliminary experiments, 22 shells were fired at the front target, and of these only one missed the object of aim. The following are the particulars: seventeen hit the first target direct, and burst behind it; the fragments penetrating the second one; three grazed and burst immediately in front of the first target, and perforated both with the pieces; one hit the bottom of the first target and exploded in the ground, and the remaining one missed entirely and burst on some rocks nearly in line beyond. A strong side wind was blowing at the time, and accounted for the deviation of this single shell. Four shells and three shot were then fired at an elevation of six degrees, from a distance of 2,000, or, more accurately, 1,964 yards. All these struck within the breadth of the target; but, the elevation being scarcely sufficient, they all fell a little short except one shell, which, ranging somewhat further than the others, hit the target and burst as usual. The results of this shell-firing were as follow: the front target contained 51 holes and the back one 164, while the ground between and adjacent to the targets exhibited about 70 perforations by fragments of shells, the greater portion of which were afterwards recovered by digging. With respect to ranges exceeding 2,000 yards, I may state that on previous occasions the gun had been tried up to 3,000 yards—a distance that was reached with an elevation of 11 degrees, and the usual charge of 10 ounces of powder, or ⅓th the weight of the projectile. By augmenting the charge the range is increased, but the accuracy is impaired, and I therefore adhere to the 10-ounce charge, which gives ample penetration, as the experiments at the butt will testify. I may also observe that the ranges obtained with this charge bear a favourable comparison with those of the heaviest round-shot guns fired with a much larger proportion of powder. It is a curious fact, and one which greatly increases the efficiency of the shells, that owing to the bursting charge requiring a minute space of time to mature its ignition after the firing of the fuse by impact, the shell is enabled to travel four or five feet after striking an object before disruption takes place. Hence, therefore, it acts as a shot before it bursts as a shell. When it perforates a target, the explosion may be seen to take place a few feet beyond, and when it grazes it has time to rise, and may be observed to burst after clearing the ground. If, therefore, it were fired against a ship, it would first penetrate the side in its entirety, and then, bursting, traverse the decks in fragments; or, if directed against troops, it would pierce the front line as a bullet, and operate like grape shot beyond. The shells explode with equal certainty whether the first substance struck be hard or soft, and, in fact, they even burst on the surface of water, providing the elevation of the gun be not too great. The bursting-charge is very small, but it suffices to break the shell into about 30 pieces, which pursue their forward course without too much dispersion. It is impossible to contemplate the results obtained with this gun without being impressed with the important part it is calculated to perform in warfare. Opposed to any ordinary field piece, it would be like the Minié rifle against the old musket, and no gun could be worked at an embrazure if a fire of shells were directed against it by one of these rifled pieces placed within the distance of a mile. In naval operations, also, guns of this description, but of larger size, might apparently be applied with great effect, more especially as a system of breech-loading, combined with a self-recovering recoil action, would be peculiarly advantageous in firing from port-holes. Even light 5-pounders, sending their shells from great distances through the sides of a ship and sweeping the decks with fragments of lead and iron, would produce very destructive effects, and a small swift steamer carrying a few such guns might prove a very troublesome opponent to a large ship of war. But if the dimensions of the gun were increased so as to adapt it for shells of 20 lbs. or 30 lbs., still more terrible injury could be inflicted at greater distances, and the powerful artillery now used at sea would be of little service when opposed to the accurate and long-ran

Digitized by Google

firing of such rifled shell guns. It now only remains to be stated, that in the course of the long series of experiments made with this gun it has been fired nearly 1,300 times without sustaining any permanent injury either in the breech-loading arrangement or otherwise. The only parts exposed to wear (and none are seriously so) are separable from the gun, and can with great facility be renewed.

"I am, Sir, your obedient servant,
"W. G. ARMSTRONG.

"Elswick Engine Works, Newcastle-upon-Tyne."

There is one feature of the Armstrong gun upon which a few words must be said before we proceed further. In Capt. Younghusband's paper we read :—"The arrangement for loading "at the breech consists of a powerful screw, "having a hole through the centre in the pro- "longed line of the bore, *through which hole the "bullet and charge are delivered* into the gun." Now, in the elaborate description of the new weapon which we gave in a recent number, no mention was made of the hole through the screw, but in the succeeding number we repaired the omission, and gave an explanation exactly corresponding with the words of Captain Younghusband just quoted. We have now, however, to state that the practice of Sir William Armstrong in regard to this feature of his gun is not uniform. The gun with which his best results were lately attained at Shoeburyness was loaded, not through the screw, but through the aperture in the breech, precisely as was described in our article; the only additional fact which needs to be mentioned in this connection being this—that the screw in the breech has a passage through it for admitting a bolt or ramrod by which the charge is forced forward into its place before the moveable breech piece is returned to its position in the gun. The cause of the slight variations of statement which we have fallen into upon this point is to be found solely in the fact that some of Sir William Armstrong's guns have been charged through the screw (like that tried at Shoeburyness in 1856, and described by Captain Younghusband) and others through the chamber in the upper side of the gun (like that tried at Shoeburyness recently, and described in our former article).

If the Armstrong gun be examined like any other invention, and the novelty of its principal features be tested by the same process as the novelty of other patented contrivances, viz., by a reference to the records of what has before been accomplished by others, we shall find very little originality in it to admire—in so far, that is, as its parts taken separately are concerned. In order to illustrate this we will not go to the Halls of the United Service Institution, or to the Tower of London, or to the British Museum, to drag to light the half-forgotten devices of other nations and ages, although we know perfectly well that some, at least, of the characteristic features of the new weapon are to be found there without difficulty. We will content ourselves with simply glancing back over the fire-arms which have been patented in England during the last century or so, and observing in which of them the improvements of Sir William Armstrong have been anticipated. Let us take, first, the prolongation of the bore through the breech, which he in some cases resorts to, and what do we find? One hundred and eighteen years ago (June 4, 1741) a Mr. Gilbert Hadley obtained a patent for a piece of ordnance or cannon of which we read (in the official abridgement of the specifications of patents for fire-arms), "the piece is breech "loading and is made of brass, or ordinary gun "metal, *and the bore goes quite through from "muzzle to breech*." Again, thirty years ago (Sept. 9, 1829), John Tucker patented an improved cannon in which not only did the bore pass out through the breech, but through a conical plug in breech, the plug corresponding of course to the screw of the Armstrong gun; the words are, "the bore is made through the "cannon, and in the breech end is inserted a "conical plug which is pierced with a hole "corresponding with the bore." Again, nine years ago (October 6, 1850) Alexander Melville and Edward Callow patented a cannon with the self-same feature, for a "plug" is used "per- "forated with a hole corresponding with the "bore." And yet again, seven years ago (April 24, 1852), Messrs. Church, Goddard, and Middleton patented, not the passage through the cannon only, but that in combination with another feature of Sir William's gun—the "slot" for the breech piece—for they claimed "the use of a clear passage extending from end "to end of the cannon, in common with a "vertical, horizontal, or other slot made across "the bore or passage, and in which slot are "fitted filling pieces with inclined surfaces, "whereby the passage through the cannon may "be opened or closed when required." If we pass to another most important feature of the new arm, viz., the use of an expanding facet of copper for closing the breech, we meet with facts of the same kind. Forty-three years since (May 14, 1816), Samuel Jean Pauly obtained a patent, from the specification of which we extract the following words :—"The "difficulty of producing an air-tight or perfect "closure between the moveable breech and the "body or remainder of the gun in breech- "loading fire-arms is obviated by using a plug "which is so placed in the gun as to come "between the charge of gunpowder and the "moveable breeching in all cases, and is "formed of lead, *copper*, or such other ductile "materials as will give way to the explosive "force of the charge, and will so cover and "close up the joint." Again, nine years since (Jan. 11, 1850) Matthew Urlwin Sears patented a cannon "on the front of the breech" of which was "a ring or washer of soft brass or "*copper*, to improve the shutting and make a "fast joint;" if we come to later times we could multiply such instances. But we turn to a third, and still more important feature. "With "a view to strength and durability," said Sir William, in his letter to the *Times*, "the gun "[his own gun] is composed internally of steel, "and externally of wrought iron, applied in a "twisted or spiral form," the twists or spirals being laid, as we know, in opposite directions. Now, whatever the object of Sir William in adopting this mode of construction may have been, the mode itself was by no means novel, for in 1854—to go no further—Mr. John Simon Holland patented it; he made "barrels of small guns" by "twisting wire round a central core in right and left-handed spirals," and cannon "by similarly twisting larger rods." But there is more in this feature than appears on the surface. Captain Younghusband, in his paper on the Armstrong gun, tells us that twisted cylinders of wrought iron," made in a similar manner to gun-barrels, were "tightly contracted upon the steel core by the usual process of cooling after previous expansion by heat," and "that *the parts are then in that state of initial tension which is necessary to bring their entire strength into operation*." Now, here we have a system of construction of very great importance—a system which appears to be slowly becoming indispensable in all modern ordnance. But to whom is its invention due? Not to Sir William Armstrong, but to Captain Blakely. For some years past that officer has been urging its adoption upon the War Department, and bringing to bear upon its advocacy not only the costly examples of guns constructed at his own expense, but mathematical investigations of a high and refined nature likewise. We are the more anxious to express ourselves strongly upon this point because, in our former article on the Armstrong gun, we neglected to do Captain Blakely justice in reference to it. And beside Captain Blakely there is another gentleman who, at about the same time as he, devised this system of construction, and went to great expense in bringing it before the public. We allude to Mr. Robert Mallet, the inventor of the monster mortars in which Lord Palmerston has taken so warm an interest. Mr. Mallet, with the aid of Dr. Hart of Dublin, published a most valuable treatise on this and some other important and kindred subjects, two or three years ago. It is but doing simple justice to these gentlemen to give them the credit of having independently invented this promising improvement. If we turn to the projectiles used by Sir William Armstrong we find as great a want of novelty as we have already found in his gun. The coating of a cast-iron shot with lead or other soft metal was patented as long ago as 1808, by a Mr. George Richards, who tells us that, according to his invention, for rifled cannon cast-iron shot are used "coated with pure tin and iron, with a proper quantity of lead to suit the chambers and to give way to the pressure of the rifles." Later, in 1852, Mr James Lawrence patented an invention in which "projectiles were cast of two or more metals combined, one being hard for striking an object the other soft so that it may be made to expand and fit the bore of the barrel." The same plan has often been resorted to since that period. If, finally, we consider the percussion fuse of Sir William Armstrong, we shall see in it even a more manifest resemblance to other inventions, if that be possible, than any yet adduced. In order to put the case simply and intelligibly we will place the official descriptions of the two preceding inventions by the side of Sir William's in parallel columns, and in the order of their dates :—

John Tucker's Patent, 1829.	C. Lancaster's Patent, 1851.	Sir W. Armstrong's Patent, 1858.
"The shell contains a hollow tube in which slides a loose bar or striker. At one end of the tube is the fulminating powder communicating with the bursting charge. When the shell is fired the striker is at the end of the tube not primed; when it strikes against an object the momentum causes the striker to impinge against the fulminating powder, and causes it to explode." (*Abrig. Spec.*)	"Shells may be exploded on striking against an object by fitting in the centre of the breech end a screwed tube; in this tube is a loose cylindrical weight of lead carrying on its head or fore-part a percussion cap. The tube is thus enclosed in the powder in the axis of the shell; it is taper at the breech end, and has a nipple at fore end. When the shell is fired the weight is thrown to the breech end of the tube, but when the shell strikes an object it is thrown forward to the other end, and the fore part strikes its percussion cap against the nipple, and explodes the shell. (*Abrig. Spec.*)	"In a cylindrical case within the shell Mr. Armstrong fixes a weight or striker, by means of a pin passing through it and the sides of the case. This pin is cut or broken by the shock which the projectile receives in the gun at the instant of firing, and the striker, being thus liberated, recedes to the near end of the case, and there remains, until the velocity of the shell is checked by coming into contact with some object. When this takes place, the striker, not participating in the retardation of the shell, advances in the case, and causes a patch of detonating composition to be carried suddenly against a fixed point, which fires the composition and ignites the bursting charge in the shell. (Mechanics' Magazine Feb., 25, 1859, p. 141.

We have now, we presume, shown with sufficient clearness and fulness that the principal features of the Armstrong gun and projectile are by no means new. There remains, however, much to be said in their favour, notwithstanding all this.

Viewed as a combination of various well-known parts, and as an instrument for projecting shot and shell over great ranges with pre-

Digitized by Google

cision, under favourable circumstances, the Armstrong gun is both a beautiful and a wonderful production. Nothing like the firing made with this gun at Shoeburyness has ever before been seen. To the artillerist it is a most pleasant sight to witness Sir William peering through his class at a target 1000 yards distant, and as the shot strikes exclaiming with perfect coolness, "Too low by three inches," or words equally indicative of nicety. But this, be it remembered, is on the practising ground, with carefully constructed sights, and other delicate appliances—not on board a ship in a seaway, nor in the field of battle. How will it work there? is the question. Now, we must say, although not without regret, that we have but little ground for expecting much of this gun as an instrument of actual warfare, either on board ship or in the field, notwithstanding all that we have heard respecting it. Nor, in saying this, are we in the least unmindful of what has been done, and is still doing, by the Government to introduce its manufacture. The Government have done something, and mean to do much more in this respect, but we doubt if the laws of nature will permit them to carry out their designs. It is easy for the Government—and especially for the Government acting under a "certain influence"—to knight an engineer, to build new factories, to construct breech-loading guns of the kind they are pleased to prefer, and to promise great results to the nation. But can Government prevent moisture rusting metal, or rust choking up screw-threads, or lead clinging to rifle grooves, or any other of the evils to which guns of this kind are liable? It is only by a bountiful supply of water during the firing that the new gun is kept in good condition; but has field artillery never to be used where water is scarce? It is only by the most careful attention, as every engineer knows, that screw-threads and other close fitting surfaces can be kept in good order when exposed to the weather; but are ships at sea never so beset by gales and storms for days together as to render it impracticable for men to unscrew and grease all the guns on board of them? It has been the habit of men in office to consider these matters important; it is fashionable now, for the moment, to ignore them; but warm lead will cling to grooved iron, whatever our whim may be, and oxygen will not lose its appetite for any fashion of ours. We mention these things as checks and warnings only, and not with a desire to detract from the real merits of Sir William Armstrong's invention. Under some circumstances the light long-range cannon will doubtless prove very useful to us, and it is possible that the principles of its construction may prove applicable to guns of far greater power than the small experimental cannons which alone have hitherto been tested. But let us not indulge in extravagant expectations, or suppose for a single moment that Mr. Whitworth and other improvers of our artillery have any cause whatever to halt in their patriotic labours.

Mr. F. Trevithick, of Penzance, has patented a curious pair of improvements in the "sails and keels of vessels." He constructs the sails of strips or narrow bands of thin sheet metal, which he combines together by means of chains or wire ropes stretched between yards or booms, and for fore and aft sails the strips or narrow bands may be arranged in an upright position, and connected by means of chains or wire ropes, so as to wind round a revolving mast. In applying keels, fixed tubes are used at intervals, parallel with the centre of flat bottomed boats or vessels. Through these tubes chains are passed to which the keels are attached, and other chains pass over the sides of the vessels, which are also attached to the keels, and by which the kneels may either be lifted into the vessel or be brought to act as lee boards.

THE ESTIMATES OF THE ENGLISH AND FRENCH NAVIES.

(Continued from p. 249.)

The third branch of the inquiry is at once the most confidential and the most difficult, namely, the state of preparation of France, in respect of powerful screw-steamers, and the expenditure which has taken place, and is still going on, in her dockyards, as compared with our own. There are many difficulties in instituting the comparison with certainty and accuracy. Whilst the reporters have been fully informed, through the officers of the Admiralty, with regard to the number, armament, condition, capabilities, and even defects of every ship in Her Majesty's service, their knowledge of the condition and effectiveness of French ships-of-war is imperfect; the returns which they have received from the confidential communications made to the Admiralty, may be relied upon as accurate with regard to the tonnage, guns, and horse-power of the French navy; but with regard to fitness for sea, durability, and general efficiency as ships of war, they are deficient in the information and critical knowledge respecting each ship of the French navy, which the responsible officers of France can alone be supposed to possess.

At the outbreak of the French revolutionary war, England possessed 115 sail of the line, France 77. These comparative numbers were reduced in 1850 to 86 England, and 45 France. At this latter period, the effective strength of the two navies in line-of-battle ships exclusively, and almost exclusively in frigates, consisted of sailing-vessels; but the French, having subsequently decided on, and nearly carried out, the conversion of all their sailing-ships that were fit for it into steam-ships, as sailing-ships could not be opposed to steam-ships with any chance of success, the latter must now be considered as the only ships really effective for purposes of war, and the following is at present the relative strength of the two navies in steam line-of-battle ships and frigates, including ships building and converting:

	Line-of-Battle Ships.		Frigates.	
	English.	French.	English.	French.
December, 1858: Complete, Hull and Machinery	29	29	Scr. 17 / Pad. 9 = 26	Scr. 15 / Pad. 19 = 34
Receiving Engns.	4	2	2	3
Converting	7	4	0	1
Building	10	5	6	8
TOTAL.....	50	40	34	46
Iron-plated Ships Building		4		

It will be seen from the foregoing statement, that England and France have at present precisely the same number of steam line-of-battle ships complete, that France has eight more steam-frigates complete, that, on the completion of the ships now in progress, England will have 10 steam line-of-battle ships more than France, and France 12 steam-frigates more than England; and it is to be observed with reference to the line-of-battle ships "building," that the five French are in a much more forward state, and represent more work actually executed than the 10 English; the quantity of work executed on the former being $\frac{3}{4}$ths; whereas, on the 10 building in England, it is only a fraction more than $\frac{1}{2}$ths. It is, however, to be observed, that of the 10 English ships building, three are three-deckers, of which class the French are not building any. France will also have four iron-sided ships, with engines of 800 or 900 horse-power. It is stated, that these iron-sided ships, of which two are more than half completed, will be substituted for line-of-battle ships; their timbers are of the scantling of a three-decker; they are to have 36 heavy guns, most of them rifled 50-pounders, which will throw an 80 lb. hollow percussion shot; they will be cased with iron; and so convinced do naval men seem to be in France of the irresistible qualities of these ships, that they are of opinion that no more ships of the line will be laid down, and that in 10 years that class of vessels will have become obsolete. In addition to the 50 steam line-of-battle ships (English) above enumerated as "built," "building," and "converting," there are six sailing line-of-battle ships proposed to be converted into steam-ships. These six would raise the number of English screw-ships of the line to 56; and if the estimates for artificers, and the purchase of ship-building materials, as proposed by the Surveyor of the Navy, be assented to, the whole could be completed by the year 1861. At the present rate and mode of expenditure in the dockyards, it is estimated that 43 only would be ready by 1861; and according to the present scheme of work, the French would then possess 40 screw line-of-battle ships, and four iron-sided ships. With the existing establishment of shipwrights and scheme of work, the number of our screw line-of-battle ships could not be raised to 56 before the year 1863, and it may be inferred that, in the interval between 1861 and 1863, still further additions will have been made to the French steam navy. In addition to the 40 steam line-of-battle ships, and four iron-sided ships (French) built, building, and converting, the Hercule and Jemmappes are supposed to be in a fit state for conversion, but it is doubtful whether they are to be converted as line-of-battle ships, or to be cut down and plated with iron. Two more iron-sided ships are to be built as the reporters are informed. These, with the two line-of-battle ships, if converted, would raise the number to 48 in 1861, as compared with the 56 English before referred to.

It was calculated last year, by the commission of naval officers appointed by the Emperor to revise the organisation of the navy, that the French would have, by the year 1860, a steam-fleet which, with a proportion of large transports, would enable them to carry an army of 60,000 men, with all its horses, provisions, and materials for one month; and that they may have ready by 1860, 40 steam line-of-battle ships, six iron-plated frigates, 30 screw frigates, 19 paddle-wheel frigates, and 26 steam-transports.

The following is a comparison between the force of English and French steam line-of-battle ships and frigates at present built, building, and converting, in respect of guns and horse-power:—

	No.	Total.	Guns.	Total.	Horse-power.	Total.
ENGLISH.

Building, &c.	9		442		3,300	
Total Line-of-battle Ships and Frigates	...	86	...	5294	.....	46,890

In addition,—

France has four iron-sided ships building, to carry 26 guns each, with 800 or 900 horse-power.

England has nine block-ships afloat, each carrying 60 guns, with from 200 to 450 horse-power.

It is necessary to observe that nine of the English line-of-battle ships, carrying collectively 720 guns, and engines of 3,600 horse-power, are 80-gun converted ships, and reported to be inferior

Digitized by Google

to the French ships of the same class. On the other hand, England has 15 ships of 100 guns and upwards, carrying collectively 1,694 guns, and engines of 10,800 horse-power; while France has only six ships of 100 guns and upwards, with 700 guns, and 3,590 horse-power.

In 1852, the horse-power of the engines belonging to the English navy was 44,482; to the French navy, 27,240. Since that year, England and France have advanced *pari passu* in the increase of the horse-power of their steam navies, and, consequently, England has not at present the same relative superiority over France which she then possessed. Since 1852, 55,030 horse-power has been added to the English navy; 54,804 to the French, including, in both cases, the engines in course of construction, and which may be ready by the end of this year; showing a difference of only 226 horse-power increase within this period in favour of England; 18,700 horse-power of the increase to the English navy has been on account of line-of-battle ships; to the French navy 24,640 and 3,600 for the iron-sided frigates, equal to 28,240, or nearly 10,000 horse-power more than the increase to the English Navy as respects this description of vessels: 7,793 has been added to the horse-power of engines for frigates and block-ships (English), 13,100 for frigates (French), total addition to the horse-power of engines for line-of-battle ships and frigates since 1852:—

England	26,493
France	41,340
Difference in favour of France in the period	14,847

It will thus be seen that since 1852, France has added considerably more than England to the horse-power of engines of the more powerful classes of vessels. On the other hand England has added 15,073 in excess of France to the horse-power of engines for vessels below the rank of frigates, viz:—

England (including 8,690 for gunboats) ...	28,537
France (including 2,240 for gunboats)	13,464
Difference in favour of England in the period	15,073

The aggregate horse-power of the English Navy, at the end of this year, will be 99,512; of the French, 82,044.

We shall now proceed to state the result of our inquiries as regards ships of all classes, dockyards, stores, and expenditure in the French Navy, comparing the state of that navy in 1852 and 1858, and with our own at the same periods. In the year 1852, the comparative numbers of British and French ships of war will be seen from the following Tables:—

STEAM-VESSELS (1852).

Classes.	England. Afloat.	England. Buildg.	England. Total.	France. Afloat.	France. Buildg.	France. Total.

Note on the foregoing Table.—The number of English vessels is founded upon returns furnished by the Surveyor of the Navy, and the comparison has been made in the presence of that officer, and a list is appended of the sailing ships which he considers as effective. The number of French vessels is based upon the latest information received at the Admiralty. Of the 35 British sailing line-of-battle ships, the Surveyor of the Navy proposes to convert 6 of them into screw line-of-battle ships as soon as possible; and he is now considering whether others may not be converted into screw-frigates. Of the 10 French sailing line-of-battle ships, it is stated that all but two are too old to be converted. No line-of-battle ship has been laid down since 1855, in France, and there has not been a single three-decker on the stocks since that year. Of the line-of-battle ships now building in the English dockyards, one was laid down in 1855, two in 1856, one in 1857, and four in 1858.

(To be concluded in our next.)

THE LANCASTER AND ENFIELD RIFLES.

WE desire to strengthen the article which appeared in this Magazine on Friday last on the Lancaster and Enfield rifles by reproducing the following remarks which appeared in the *Times* of the next day:—

"The important disclosures which have recently been made public relative to the alleged defects in the Enfield rifle used by the British troops in India have been the means of directing the attention of the authorities to the vast superiority, as a weapon in the hands of troops, of the Lancaster rifled carbines, with which the corps of Royal Engineers is now armed. From the reports which have recently been received by the authorities at the Horse Guards from the officers now serving with the Royal Engineers in India, there can be no doubt that the Lancaster rifle is in every respect superior to any small arm in the service, repeated proofs of which were given during the conflicts with the mutineers in India. Four companies of the Royal Engineers have been employed in India during the rebellion, all armed with the Lancaster carbine, and the same tests which applied to the Enfield rifle proved it to be defective have resulted in the Lancaster rifle maintaining its efficiency. The officers report that there has not been a single complaint of fouling, difficulty of loading, or want of accuracy and power, brought against it; but, on the contrary, it has proved, in every respect, superior to the Enfield rifle. During the frequent conflicts with the mutineers in which the men of the Royal Engineers and the troops of the line have been engaged together, with the same amount of ammunition issued to all the troops engaged, the men of the line regiments have been compelled to cease firing for the purpose of wiping out the barrels of their Enfield rifles after firing from 10 to 20 rounds, whereas the Royal Engineers, with the Lancaster rifle, have continued their fire, loading their carbines with perfect ease. On the 21st February, in last year, the 4th company of Royal Engineers, consisting of about 100 non-commissioned officers and men, was stationed at Fort Jellalabad, before Lucknow. The enemy attacked the fort in great numbers, and went close to the walls. They were, however, repulsed by the Royal Engineers with great loss, no less than 90 men being left dead on the ground, the whole being killed by the Lancaster rifles. No idea could be formed of the number of killed and wounded carried off, but no doubt it was considerable. The Royal Engineers sustained no loss; not a man was even wounded. This fact is most important, not so much as showing the accuracy of the arm, but from the circumstance that during the six hours the Royal Engineers were engaged with the rebels until relieved by Sir J. Outram's force, each man fired on an average at least 60 rounds, and yet not the least difficulty was experienced during the whole of that time in loading the carbines. The only thing observable was, that with some the bullet became a little tighter than usual as it approached the breech when rammed down the barrel, and with others that there was an increased recoil. If the defects pointed out in the Enfield rifle and the difficulty with which it is loaded after several rounds have been fired from it, resulted from the expansive action of the barrel against the bands, or against the bayonet socket and its ring, causing an indentation of its outer surface, and consequent contraction of the bore at those places, the defect would be permanent, and nothing but a mandril or cutting tool forced into the barrel could remove it. It is, however, well known that after an Enfield rifle has been wiped out with a wet or greasy rag it loads as easily and fires as well as when first used, thus proving that the defect alluded to is not a permanent one produced in the metal of the barrel by expansion, but a temporary one resulting from the peculiarity of bore retaining the maximum amount of deposit from the powder charge. On the other hand, the peculiarity of the Lancaster bore, judging from its performance under the same circumstances, and with the same ammunition, appears to be such that it retains only the minimum amount of deposit, while at the same time its range and accuracy are greater. In the last-mentioned qualities it has been frequently proved to excel the Enfield rifle in England as well as India. Both rifles may now be considered to have had a fair trial in the very best school for testing their respective merits—namely, actual warfare, and from the unanimous testimony of officers and men, both in India and elsewhere, there can be no doubt that as a weapon in the hands of troops engaged in war the Lancaster is in every respect superior to the Enfield rifle."

We may add that during Monday and Tuesday last, large parties of non-commissioned officers and men of the Royal Engineers, belonging to the survey companies stationed in various parts of the country, arrived at head-quarters, Brompton-barracks, Chatham, for the purpose of being put through a course of instruction with the Lancaster rifle.

A SIMPLE MEANS OF DEMONSTRATING THE WORKING OF LIQUID-FIRE SHELLS.—The bisulphide of carbon is first poured into the shell, and then small bits of phosphorous are dropped in; the mouth of the shell is then closed with a cork, partly projecting, like the cork in a wine-bottle. The shell may then be laid on canvas, or other combustible matter; and in about ten minutes, the fermentation of the mixture will force its way through the pores of the cork, and, meeting the oxygen of the atmosphere, will become ignited; the cork acting like the wick of a candle, and the liquor underneath feeding it. A leaden shell thus charged, and adapted to the Lancaster military rifle, will continue to burn for ten minutes with an intense flame, which cannot be extinguished by water.—J. NORTON. [Mr. Macintosh has a patent for such shells?—Ed. *M. M.*]

Some Fijian paper has just been received by the Manchester Cotton Supply Association. It is made from the inner bark of the mulberry tree, and is an article of barter among the natives of Fiji. It is thought that the fibrous materials of the mulberry-tree might be rendered available for writing, printing, and other papers.

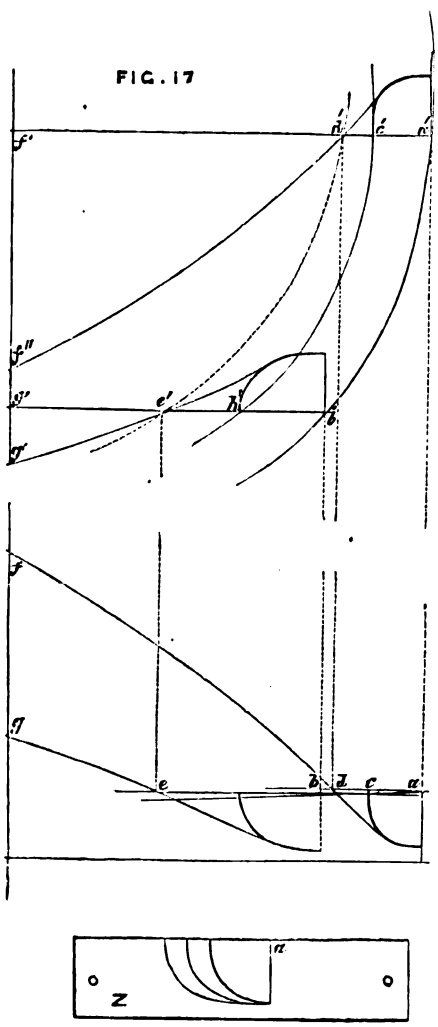
LAYING-OFF;
OR,
THE GEOMETRY OF SHIP-BUILDING.
No. V. *

THERE is one way in which the foremost extremities of the sections of a ship might be correctly ended, which will probably strike some of our readers, and that is, to draw planes perpendicular to the fore edge of rabbet of stem, and to *rabat* them on the sheer plan. The sections of the ship made by these planes will end on the backs of circles, swept with a radius equal to the thickness of the planking—the points in which the curved lines touch the circles being points in the middle of the rabbet. We shall not make the construction for this mode of solution, but shall leave our readers to do it for themselves. It will be seen that it differs from Stalkartt's method only in this—that the section made according to him is square to the vertical longitudinal plane and inclined to the horizontal plane, while that which we propose is inclined to both these planes, and may be called a double-cant section. There is, however, another mode of ending the half-breadth lines and getting the bearding, which, though but little known, commends itself to our judgment. It will be seen that if the fore edge of rabbet of stem, Fig. 15, page 186, represented the axis of a curved cylinder—if we may be allowed to use the term—the radius of which was equal to the thickness of the plank, the side of such a cylinder, or rather, series of cylinders, would be in contact with the surface of the timbers all down the stem, whatever might be the obliquity of the fore-edge of the rabbet or the taper of the stem. Now, any level plane would cut this cylinder obliquely, and the section in which it would cut it would be an ellipse, from which we see that the line in which the level plane cuts the surface of the timbers should be ended in the half-breadth plan on the back of an ellipse such as we have described. Diagonal lines and water-lines would be ended in a similar manner.

FIG. 17.



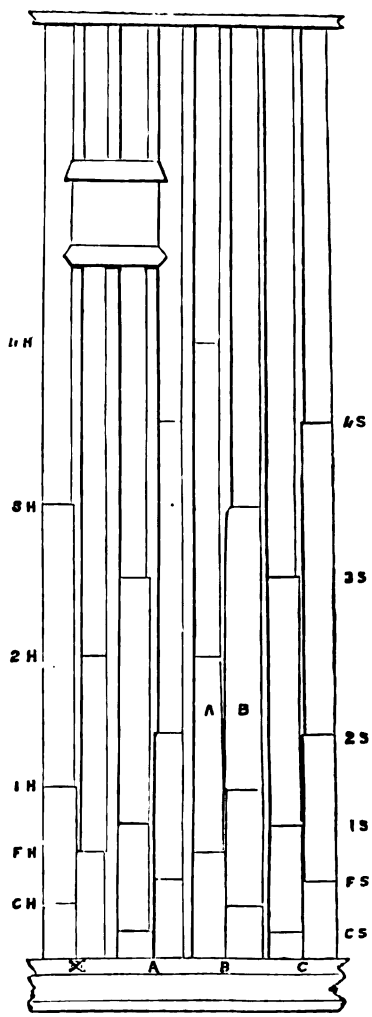
From these considerations we may obtain the bearding line more easily than by the use of Stalkartt's bow-sections, and with the same amount of precision, the only error in both cases being that the stem is assumed to be sided parallel.

To end the level lines, and obtain points in the bearding line, observe that if $a'\,b'$, Fig. 17, is the fore-edge of rabbet, and the axis of the cylinder of which we have spoken, then $c'\,h'$, drawn parallel to $a'\,b'$, and at a distance from it equal to the thickness of the planking, is the side of the cylinder. The longer semi-diameter of the elliptical section of this cylinder, made by the level plane $a'\,c'\,f'$, is $a'\,c'$, and the shorter the radius of the cylinder. And the longer semi-diameter, or the semi-major axis of the section made by the level plane $b'\,h'\,g'$ is $b'\,h'$, while the shorter is as before the radius of the cylinder or the thickness of the plank. To end the line $f\,d'$ or $f'd$ we have then to construct a segment $a\,c\,o$ of the ellipse, and end the line as shown; then d', obtained by squaring up the point d where the line cuts the side of the stem, is a point in the bearding line. The line $g\,e$, being ended in a similar way, another point e' is found in the bearding line, and so on for any number of points which may be required. We have shown the same construction in the sheer plan for the sake of illustration, by rabatting both the section of the ship and the section of the cylinder about a straight line through the point in the fore edge of rabbet and parallel to both the planes of projection, the level line $d'\,f'$ becoming $d'\,f''$, and $e'\,g'$ becoming $e'\,g''$. It must not be supposed that we should propose to construct the required ellipse at each of the endings in the half-breadth; we are quite sure no draftsman would receive such a proposition with favour; the matter might be managed very simply by drawing on a *brass plate* or piece of thin board Z, Fig. 17; a number of elliptic quadrants for the same thickness of plank, increasing the semi-major axes gradually by perhaps half-an-inch at a time from the thickness of the plank up to the greatest distance which would be practically required. Having a set of these curves for each thickness of plank, take the one which will suit the particular ship in hand, and at each level line, $b'\,g'$, for example, mark on the board or plate Z from a the distance $b'\,h'$, the point h' being found by setting off the thickness of the plank from the fore edge of rabbet in the sheer square to the curve. Then nail the plate Z upon the floor with its edge fore and aft, and the point a at the point in the fore edge of rabbet in the half-breadth plan, and let the penning batten pass over the plate, and touch the curve next within the point we have marked upon it from h'. In this way the endings of all the lines may be easily obtained, and the bearding line got in. It would require a complicated construction to determine the exact points in which the lines touched the ellipses in order to discover the middle of rabbet, but if we can get in the bearding line correctly nothing more is needed. We may observe, in passing, that the foci of the ellipse are found from the axes, by sweeping from the extremity of the shorter axis with a radius equal to half the longer, an arc of a circle, cutting the longer axis in two points. These two points are the foci from which the ellipse may be swept in. The ellipses for ending level lines when the taper of the stem is considered, and for ending the diagonal lines, cannot be determined with sufficient simplicity for practice, because the major axis does not lie in a fore and aft plane, and, therefore, cannot be measured at once on the sheer.

Having thus shown how the various sections of the surface of a ship may be got in, and ended we must now show, in detail, how some of the principal parts of the ship are laid-off.

Throughout the greater portion of the ship the sides of the ribs or frames lie in vertical transverse planes, and the shapes of their outer edges are shown by the sections of the surface of the ship inside the planking made by such planes and projected on the body plan. Each frame consists of short pieces of timber, called cross-pieces, floors, half-floors, and futtocks, according to their positions—which pieces are arranged in two series, one piece rising above another, as shown in Fig. 18:—

FIG. 18.



C S, cross-sirmark; *C H*, cross-head; *F S*, floor-sirmark; *F H*, floor-head; *1 S*, first-sirmark; *1 H*, first-head, &c.

The adjacent sides of the lower pieces in each frame touch each other, but between those of the upper pieces there is an interval of a few inches. There is, however, an imaginary surface of contact from the bottom to the top of the frame in continuation of that formed by the lower pieces—this imaginary surface is called the *joint* of the frame. The distance between two joints, which is a few inches greater than twice the size of the lower pieces in the frame, is called the *room and space*, or timber and space. At every joint a vertical transverse section of the ship is taken, and it is these sections which are delineated on the floor, as shown in Fig. 19.

To each section moulds of thin wood are made, which extend from the keel to the gunwale, and indicate to the workmen the form of the *joint-edge* of each of the pieces in the frame—the distance between the joint and the edge of the timber being so small as to cause no appreciable difference in the form. But the side farther from the joint in each of these pieces, called the *bevelling-edge*, being a foot or more before or

* N.B.—Page 186, first column, line 25 from the bottom—for *level* read *expanded*.

Digitized by Google

abaft the joint, will have a somewhat different form, and will require a separate determination.

FIG. 19.

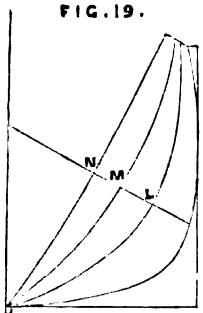


FIG. 20.

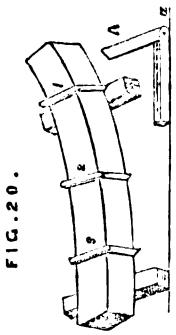

For this purpose it is not necessary to find on the floor the shape of a complete section of the ship at this new position; we are content to discover a few points in the curve, its general character being determined by that of the joint. Let us suppose that the workman has trimmed to shape the joint-edges of the timbers marked *A B*, in (Fig. 18), and that he wishes to know the form of the bevelling edges. Now, if we can give him, by means of the *bevel A* (Fig. 20), consisting of two pieces of wood pivoted at *a*—if we can give him, by means of this instrument, the angle between the two arms of the bevel when it is applied at several fixed points along the timber, one arm being held square to the side of the piece and the other to the joint edge, he will then be able to tell how much he must cut from the face of the timber at these positions, and will thus find points in the curve of the opposite edge, if he joins these by the mould for the joint edge, he will have the entire bevelling-edge. It remains, then, to find these angles or bevellings for the timbers *A* and *B* at the several diagonals.

Let *M* (Fig. 19) be the joint-edge of *A* and *B*, or of two timbers similarly situated to *A* and *B* in any frame, and let *N* and *L* be the adjacent joints. Then, if it be required to find the bevelling at *M*, draw through this point a line, *N L*, square to the curve at *M*. Now, the real distance from *M* to *N* is the hypothenuse of a right-angled triangle, the base of which is the length *M N*, and the perpendicular the distance between the transverse planes containing *M* and *N*—*i.e.*, the *room and space*. If, then, we set off from the edge of a table (Fig. 21) a line square to its side equal to the

FIG. 21.

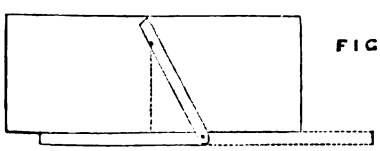

FIG. 22.

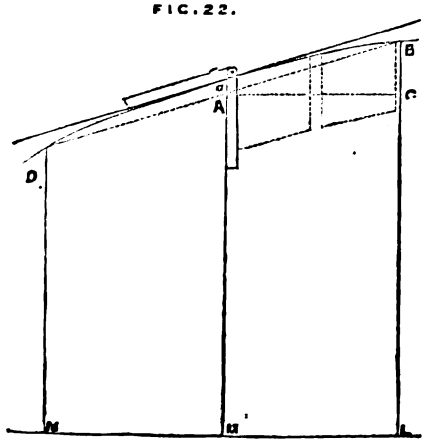

room and space, and from it measure along the edge of the table a distance equal to *M N*—then the bevel set as shown will give the angle between the side and the face of the timber at *M* in a plane at right angles to the joint-edge. See Fig. 22.

If *M L* be set off in the same manner, instead of *M N*, we should get the bevelling at the point *M* of the timber on the other side the joint. But it is not usual to get both these bevellings, it being assumed that the side of the ship is straight for a little distance before and abaft the joint, and that the two bevellings will therefore be equal to two right angles. To obtain the second bevelling, the stock of the bevel is turned round, as shown by the dotted lines in (Fig. 21). But as the distances *M N* and *M L* are generally unequal, it is evident that neither of them can give the correct bevelling for both; it has therefore been proposed to take half the distance between *L* and *N* for the base of the triangle, instead of taking either *M N* or *M L*; by this means we obtain the angle *A B C*, Fig. 22, because *A C* is the room and space, and *B C* is half the distance between *L* and *N*; the curve *B D* being the expanded diagonal, at the height at which we are bevelling. This angle will generally be the same as that made by a line *touching* the curve at the point *a*, because *a* being generally the highest point in the curve, a tangent at it will be parallel to *D B*, and it is the direction of this tangent which is really required.

CANT TIMBERS.

If the sides of the frames at the extremities of the ship where her sides make a considerable angle with the transverse plane still lay in transverse planes, the sections of the timbers would be acute-angled parallelograms, requiring very large timber for their conversion, and would be besides ill-adapted to receive bolts driven in square to the surface. On this account a change is made in the direction of the sides of the timber when the sides of the ship begin to turn inwards considerably. The planes in which they lie are still vertical planes, or perpendicular to the horizontal plane, but they are no longer parallel to the plane of the body. Their inclination to this plane increases gradually as we advance towards the extremity of the ship, and the plane of the foremost one is nearly fore-and-aft. By this means the sides of these timbers are made nearly square to the curvature of the bottom, and the inconveniences mentioned above are avoided. All the timbers in these oblique sections are called *cants*, or cant timbers, and the frames which they compose, *cant frames*.

HARPINS.

Harpins are wooden bands running round the outer surface of the timbers at the heads of the different futtocks, or portions of the ribs. They are cut out of elm plank about six inches thick, and are made up in several lengths scarphed together. They are intended to indicate the form of the body of the ship, and to determine the position of the timbers; they are therefore made strong enough to prevent them from bending when they are fastened to the stem or sternpost at one end, and to a frame or rib at a considerable distance from it on the other, receiving support from shores in intermediate positions. As the different timbers, or frames, are brought into place, they are supported by these harpins, and are secured to them by screws. They are distinguished by the names of the heads of the futtocks at which they are placed, as floor harpin, first-head harpin, second-head harpin, portsill harpin, topbreadth harpin, &c. The upper surface of each of the harpins at the heads of the timbers, lies in the diagonal plane which, as we have already pointed out, determines the position of the heads. It will be seen by Fig. 18, that there are rows of timber heads called sirmarks between those marked heads. No harpins are made to these, although the diagonal curves are got in upon the floor. The original use of these intermediate diagonals was to assign the positions of the bevelling stations on the timbers, not to mark the heads of futtocks; but by the introduction of "filling frames," made up with pieces of a different length from those employed in the regular frames, the sirmarks have become heads. They still, however, answer the end for which they were originally designed.

RIBBANDS.

Throughout all the midship portion of the ship these bands consist only of fir quartering from four to six inches square, *bent* round the timbers, and secured to them by screws as a means of regulating them, rather than of fixing their proper positions, as that is done with sufficient precision by the cross-spalls, &c. This quartering is called *ribband*; its *upper* side makes a continuous line with the *under* side of the harpins, and is therefore about six inches below the plane of the diagonal. Moulds are made to the harpins only, not to the ribbands.

Proceedings of Societies.

INSTITUTION OF ENGINEERS IN SCOTLAND.

On Wednesday evening, 13th April, a meeting of this Society was held in the Philosophical Society's Hall, Dr. W. J. Macquorn Rankine, President, in the Chair. The meeting, being the concluding one of the session, was principally for the purpose of electing officer-bearers for the ensuing year. The treasurer's report showed the financial condition of the Society to be very prosperous. An interesting communication was read by Mr. Neilson, relative to the structure and arrangements of American river steamers, as compared with those of the Clyde, which in proportion to their size, are much heavier and clumsier than the "wooden palaces" which float on the rivers of the "Far West." Some of the members expressed a fear that steamers constructed on the American plan would not be strong enough to bear the rough weather to which the Clyde vessels are often exposed in the estuaries; but Mr. Neilson said that many of the American pleasure steamers had to encounter the force of the Atlantic's waves during a portion of their voyages; and he had no doubt that if shipbuilders took into consideration the proposal of building vessels for river navigation on a similar plan to that adopted in America, it would be found to be an improvement, both in point of speed and passenger accommodation. Several gentlemen expressed their belief that the subject ought to be taken up by shipbuilders. A model, showing an improved construction of rudder, the invention of Mr. Chaplin, specially adapted for vessels intended to navigate shallow rivers, was exhibited, and was very generally approved of by the meeting. Mr. Chaplin said that Government had ordered the plan to be applied to six vessels intended for the navigation of the Ganges. Messrs. R. Napier and Sons presented to the Institution the tabulated results of 300 experiments on the strength of numerous varieties of plates and bars of wrought iron and of steel. Dr. Rankine communicated and explained a useful formula for estimating the evaporative efficiency of different kinds of boilers with different kinds of coal. The anniversary dinner of the Society will take place in about a fortnight.

SOCIETY OF ARTS.

April 13.—The nineteenth ordinary meeting of the one hundred and fifth session was held on Wednesday, Wm. Fothergill Cooke, Esq., in the Chair.

The following candidates were ballotted for and duly elected members of the Society:—John Norton, William Henry Weeks, Cromwell Fleetwood Varley.

The following Institution has been taken into Union since the last announcement:—The British Horological Institute.

The paper read was:—"On Professor Hughes' System of Type-Printing Telegraphs and Methods of Insulation, with Special Reference to Submarine Cables. By Mr. H. Hyde.

GEOLOGICAL SOCIETY OF LONDON.

April 6.—Prof. J. Phillips, President, in the Chair J. Phillips, Esq., Claremont Lodge, Brixton-road: C. Gould, Esq., Geol. Survey Great Britain; J. E. Lee, Esq., Priory, Caerleon, Monmouthshire; and J. Leckenby, Esq., Scarborough, were elected Fellows.

The following communication was read:—"On the Subdivisions of the Inferior Oolite in the South of England, compared with the Equivalent Beds of the same Formation on the Yorkshire Coast." By Thomas Wright, M.D., F.R.S.E. (Communicated by T. H. Huxley, Esq., Secretary G.S.) With a note on Dundry Hill, by E. Etheridge, Esq., F.G.S.

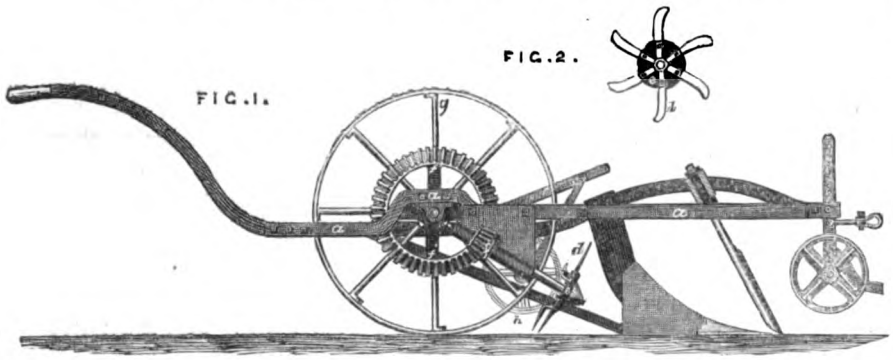
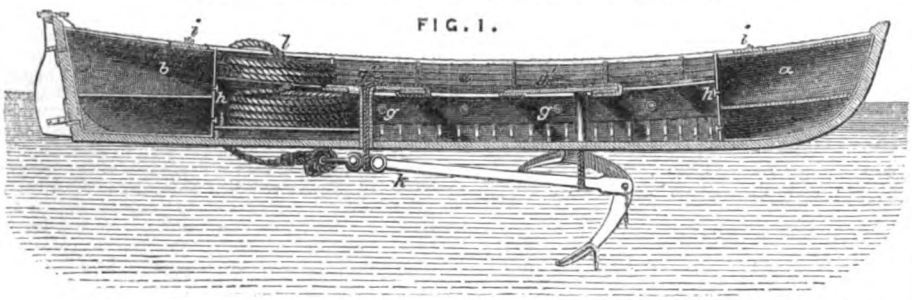
HARKE'S PLOUGH AND PULVERIZER.

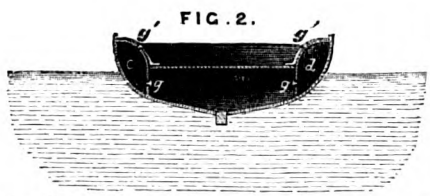


MR. WILLIAM HARKES, agricultural implement maker of Lostock Gralam, Chester, has patented an improved plough, or pulverizer, which he describes as follows:—

"The improvement consists in arranging or placing a series of cutters supported in a circular frame directly behind the ploughshare, and at right angles to it, so that as the soil leaves the ploughshare, it is delivered on to the knives, cutters, or pulverizers, which are caused to revolve rapidly by means of suitable gearing in connection with the supporting wheels of the plough, so that as the plough progresses, the knives rotate, and cut or pulverize the earth as required. The apparatus may also be employed for digging up potatoes, &c., for which purpose a series of forks may be substituted for the knives." . . . "Fig. 1 is a side view of the improved plough, showing the position of the pulverizer immediately behind the ploughshare; and Fig. 2 is a detached front view of the series of knives in a circular frame forming the pulverizer. In Fig. 1, *a a* is the frame of the plough; *b* the ploughshare, and *c* the colter; *d d* are the knives contained in the framing *e*, every alternate knife being double or fork-like, and all supplied with cutting edges, for cutting, breaking up, or pulverizing the soil as it is turned up, and leaves the ploughshare; the framing carrying the knives is mounted upon a shaft, upon which is a bevel wheel *f*, gearing into the bevel wheel *f'*, by which means motion is communicated to the knives from the bearing or driving wheels *g*, *g*, which support the central portion of the plough; *h* is an extra wheel placed on the left-hand side of the plough to assist in turning it. The ploughshare *f* is furnished with hinges, so that when required a "mould board" may be attached, and the plough may be used without the pulverizer, and as a plough only."

LAMB AND WHITE'S LIFE-BOATS.





WE alluded in our gossip columns a few weeks since to certain improvements in life-boats which had recently been introduced by Mr. Andrew Lamb, of Southampton, and Mr. John White, of Cowes. We now furnish illustrations of their invention. In the accompanying engravings, Fig. 1 is a longitudinal section of a life-boat constructed according to this invention, Fig. 2 being a cross section, Fig. 1, showing the position of the two delivery tubes, through which the anchor, which is shown as hung beneath the boat, is slung by means of rope lashings passed through the tubes (these tubes being placed a short distance from the middle line, on opposite sides of it), the lashings being so secured as to be within reach and under the command of the crew; *a* and *b* are water-tight compartments at the head and stern of the boat; *c* and *d* are water compartments or air-cases running longitudinally along the sides of the boat, and carried up to the gunwale; *e* and *f* are delivery tubes, as before described, for the purpose of freeing the boat from water, should it rise above the external level, which tubes are intended to be fitted with valves which are removeable when the boat has to be used for carrying out an anchor, and they can be replaced in a few moments when the lashings are removed; *g*, *g* are the water-plugs fitted at the lower part of the air-cases or longitudinal water-tight compartments, which in practice may be placed lower than where shown in Fig. 1; and *g'*, *g'* are the screw plugs at the top of the longitudinal air-cases or water-tight compartments, which plugs are unscrewed or removed when the boat is out of use, for the purpose of producing a circulation of air within the longitudinal air-tight cases, so as to perfectly dry and preserve the interior thereof; *h*, *h* are screw plugs fitted to the water-tight head and stern compartments, and *i*, *i* are hand-hole covers fitted on the decking or top side of each of the compartments *a* and *b*, and by the removal of which food, stores, or other articles may be deposited in safety, and kept dry; *k*, the anchor, which is slung below the boat, but at an angle with the line of the keel; *l*, *l*, the cable attached to the anchor, and coiled as shown in Fig. 1.

"Life boats, thus constructed," say the inventors, "combine lightness with great strength, which enables them to be hauled up and suspended to the ship's davits, without risk of straining or injuring the boat; the disposition of the longitudinal air-cases and head and stern compartments, gives greatly increased safety over every other construction of life-boat heretofore in use, and renders it impossible for the boat to be sunk when filled with persons, or when carrying out the heaviest anchors, suspended or slung in manner described. By the introduction of the delivery tubes the boat may be made available for carrying out safely the largest anchor from the ship in the event of her going on a lee shore, or under other circumstances, whilst, by the addition of valves, fitted to the delivery tubes, and construted to open downward for the discharge of water from within, after shipping a sea; or, when from any other cause, the water may rise above the external level, the boat is freed therefrom by permitting its escape through the delivery tubes; and by the introduction of screw plugs in the top side of the longitudinal air-cases, in addition to the water plugs at the lower part of the air cases; they may be preserved in a perfectly sound condition; thus we have combined within the same boat advantages not heretofore possessed by any other construction of life-boats."

GUN-MAKING AT WOOLWICH ARSENAL.

Of the innumerable experiments tried during the last two years at Woolwich Arsenal for the purpose of ascertaining the best way to make large guns, *one* good thing has come, at all events—the authorities and ourselves know the proper kinds of iron to use for the purpose. Failures there may have been in the subsequent stages of manipulation, but many guns were certainly cast of the best possible admixture of metal for the purpose. So long back as 1858 iron-masters and others were invited by public advertisement to send to that establishment samples of the iron they could confidently recommend for this particular branch of manufacture. Fifty samples came on this invitation. These were subjected to tests chemical and mechanical in the first instance, and selections were made from them. The result of these primary experiments demonstrated what has subsequently been completely confirmed—that English cold blast pig iron is quite equal in purity and strength to the bulk of foreign iron. Northerton and Parkhead were found in these early trials indeed to be far superior to East Indian or Nova Scotian. Swedish grey occasionally proved of very superior character, but generally it seemed extremely hard, and it could not be used therefore safely in the composition of guns. The impurities sought for in the chemical testing of the iron were silicon, sulphur, and phosphorous, and if these existed in quantities larger than 1·5 per cent. of the first; ·05 of the second; or ·5 of the third, the iron was uniformly registered. The mechanical tests were applied to ascertain the tensile and transverse strength of the material when cast into bars. Its specific gravity was also taken into account. Without going further into detail, however, upon this interesting subject at present, it may be stated—and there is some satisfaction, in a patriotic sense, in doing so—that the irons peculiarly adapted by nature for the manufacture of large guns are English, and these stand in the following order:—Northerton and Parkhead, Staffordshire; Bowling, Yorkshire; and Blaenavon, Shropshire. The cost of these averages from £6 to £6 10s. per ton, against £8 15s. to £10 per ton for foreign. The charge of metal necessary for the casting of a 68-pound gun, with the "dead heads"—the latter is used, however, in the charge for the next gun to be cast—is 8 tons or thereabouts, and the conveniency of using English irons with the certainty that they are the best becomes thus apparent. Whether the Arsenal will yet be able to *finish* these weapons in a style equal to that of certain contractors is, we believe, a problem yet to be solved.

Railway enterprises in the Eastern Counties have proved singularly unsuccessful this year. The preamble of the Bedford, Potten, and Cambridge scheme has just been declared not proved; and the London and Bury St. Edmund's and Colne Valley extension schemes have been withdrawn. Tuesday, however, witnessed the opening of the Grantham and Sleaford extension to Boston.

Messrs. Reiss and Co., the lithographers, of Dusseldorf, have lately discovered a mode of transferring pen drawings immediately from the paper to the stone in such perfection that the finest lines are rendered as successfully in the impression as the deepest shadows. In a few minutes after the delivery of the drawing, the stone is ready for the press.—*Bulletin.*

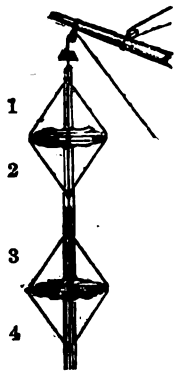
REDL'S CONE TELEGRAPH FOR THE NAVY AND WAR DEPARTMENTS.

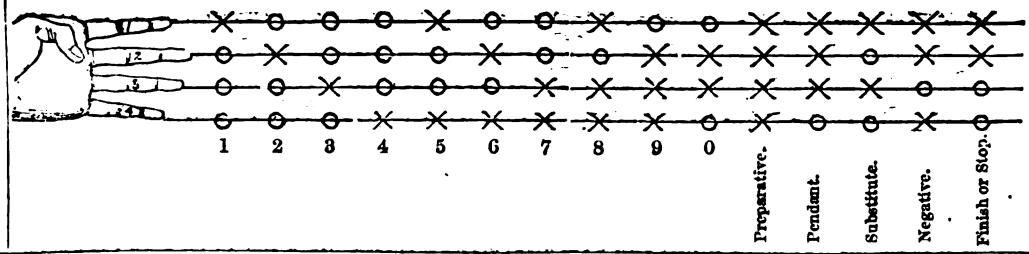


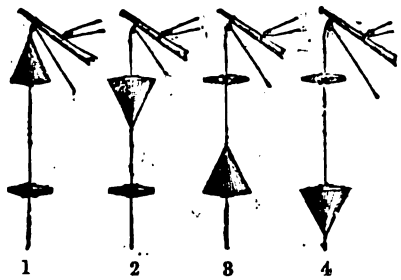
The Cone Telegraph is made by means of four collapsing cones joined in pairs at their bases, and suspended vertically under each other. These being opened or closed at will, present in every direction fifteen changes of figure. These fifteen different changes are used to represent the ten numerals, and five other auxiliary signs.

These changes may be rendered easily intelligible by considering the four fingers of one hand as the four cones, of which—

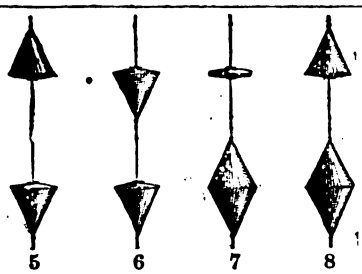
The fore finger will represent the first or upper cone.
" second ..... second cone.
" third ..... third cone.
" little ..... fourth cone.

Then if we mark a finger or cone being open by a X, and a finger or cone being closed by an O, we have

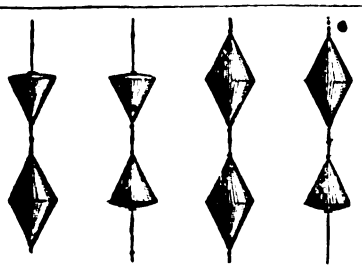




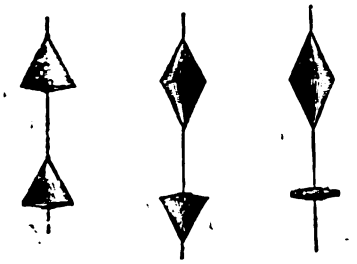
The 1st or upper cone only being *open* represents figure 1
" 2nd or next 2
" 3rd 3
" 4th or lower cone 4



The 1st and 4th cones being *open* together 5
" 2nd and 4th 6
" 3rd and 4th 7
" 1st, 3rd, and 4th 8



The 2nd, 3rd, and 4th 9
" 2nd and 3rd 0
" 1st, 2nd, 3rd, and 4th ..... Preparative.
" 1st, 2nd, and 3rd ..... Pendant.

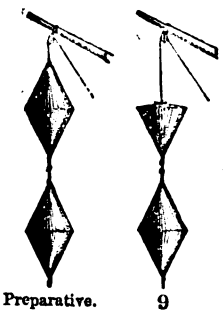


The 1st and 3rd ..... Substitute.
" 1st, 2nd, and 4th ..... Negative.
" 1st and 2nd ..... Finish or Stop.

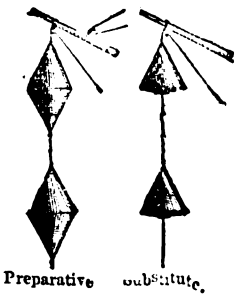
EXAMPLES.

The "*Preparative*" or all the cones open, may be used to attract attention before commencing a signal, but this use of it is not necessary under ordinary circumstances.

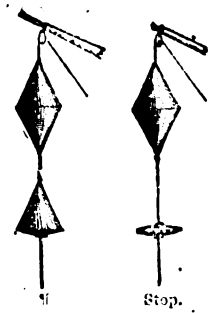
If whilst Telegraphing, either party make a mistake in the message, the "*Preparative*" should be immediately shown, and the signal is then to be repeated from the last "stop."



If after any message is received one of the signals* should on deciphering appear to have been erroneous, then the "*Prepasative*" and the number of that signal as it stands in numerical order is to be made, when that signal is to be repeated.



The "*Preparative*" followed by the "substitute" signifies that the whole message is misunderstood.

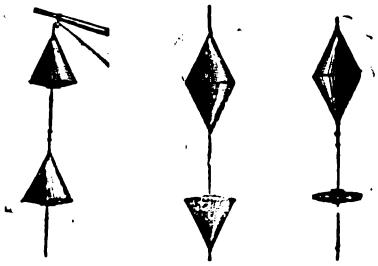


(*List of the Navy.*)

"*Pendant*" with a "stop" or figure after it, specifies the Table or Code to which the signal following refers, thus—

¶ Pendants.
(¶stop) { Union Jack or List of the Navy.
(¶ 0) Numeral.
(¶ 1) General Signal.
(¶ 2) Telegraph.
(¶ 3) Alphabetical.
(¶ 4) Geographical.
(¶ 5) Latitude and Longitude.
(¶ 6) Military.
(¶ 7) Horary.
(¶ 8) Interrogative.
(¶ 9) Compass.

* By a *signal* is meant all the figures or letters between two successive "stops."



Substitute. "*Substitute*" is made use of as the duplicate of the preceding hoist, and an affirmative answer to a question asked.

Negative. "*Negative*" is made use of as an "annul" to the preceding message, and a negative answer to a question asked.

Stop. "*Finish*" or "*Stop*" is used to separate the different numbers, words, or parts of a message, and when shown *twice* it signifies the completion of the message.

N.B. When accuracy is of importance, each hoist may be repeated.

For Alphabetical purposes, the following numbers when shown after the proper "Pendant," are used to designate the different letters of the alphabet.

		A 5		
B 6	C 7	D 8	E 9	F 10
G 11	H 12	I 13	J 14	K 15
L 16	M 17	N 18	O 19	P 20
Q 21	R 22	S 23	T 24	U 25
V 26	W 27	X 28	Y 29	Z 30

EXAMPLE OF AN ALPHABETICAL MESSAGE.

UNACCOUNTABLE EXPLOSIONS.

The following letter has been received from a gentleman whose authority to speak on this subject is known to our readers:—

Gentlemen,—In the article upon Gunpowder Manufactories in a late number several illustrations are given of a curious and important fact, viz., the variation in the stability of explosive compounds. The paragraph I allude to is the following:

"We have had enough of these accidents to convince us that gunpowder is a chemical combination of an extremely treacherous nature. Although not so uncertain as gun-cotton and fulminating silver, it is, from the difficulty of defining to what length it may be trusted, of the same coquetish family. Gun-cotton, it has been proved in the making of rockets, may be rammed by a succession of gentle taps, or by the whole force of hydraulic pressure, some nine thousand nine hundred and ninety-nine times with perfect impunity, and then a child shall drop a mere rod upon it and cause the loss of many lives. Fulminating silver may be stirred with impunity two or three times a day in a wooden bowl with a wooden stick for a period of some ten or fifteen years, and yet this simple act shall at some other time scatter into space a large factory, spread dismay throughout Bond-street and Piccadilly, and strike the ingenious inventor of wire-cartridges a corpse."

So far as regards gun-cotton and the fulminates of silver and of mercury, the fact of extraordinary instability, under certain circumstances at present unknown, cannot be denied, and it may, therefore, be sought to account for it. And if the terrible, and, apparently, unaccountable accidents which have sometimes occurred with gunpowder are sufficient to warrant our placing it in the same category, the question assumes an importance which cannot easily be overrated. But another compound exists of a far more capricious character even than the fulminates, and on which, therefore, the causes of instability may be more readily studied. This body is formed when iodine is placed in a solution of ammonia; and, if we assume that the ammonia is decomposed to form hydriodic acid, its designation would be the *iodide of amidogen*, and its formula $NH_2\,HI$. When dry, it sometimes explodes spontaneously, sometimes by the smallest concussion of the air, or the slightest touch, while occasionally it may be moved or gently handled with impunity. Once or twice, when wishing to exhibit the extraordinary explosive nature of this compound, I have been unable to cause its decomposition by anything short of a slight tap with a tolerably hard substance—a circumstance but ill-accounted for by the usual unsatisfactory explanation that it *ought* to have exploded with much greater facility. A more logical reason may probably be found in the condition of the atmosphere, as we will attempt to prove.

Let us briefly consider the action which occurs in the explosion of this compound, and the chemical affinities by which it may be occasioned. We find that the result of the explosion of $NH_2\,HI$, *i. e.*, its combination with the oxygen of the air, are:—

Iodine
Water
Nitrogen

Thus the hydrogen of our compound combines to form water. But it is by no means certain that the affinity of the hydrogen for the oxygen of the air is the primary cause of explosion; though the fact of *water* being the only compound produced might at first lead to this conclusion. There exists a body, the mere presence of which is sufficient to effect a combination with iodine, which combination is attended with some degree of heat. This is ozone, *i.e.*, oxygen in an allotropic state, having its chemical affinities exalted in a very high degree.

The following facts, therefore, enable us to come to a rational conjecture respecting the first cause of a decomposition which is attended with so great a degree of uncertainty. They are extracted from Dr. Thomson's "Cyclopædia of Chemistry":—

1. The presence of *ozone* with moisture, converts iodine into *iodic acid*.

2. Oxygen is evolved *when iodic acid is heated*, and the iodine is set free.

The *origin* of the decomposition would, therefore, be the oxidation of the iodine rather than that of hydrogen.

It remains to verify by experiment whether the affinity between iodine and oxygen in this peculiar condition facilitates the explosion of iodide of amidogen in ozonised air.

The imperfect experiments I have hitherto been able to make in connection with this investigation, appear to strengthen the view that ozone exerts a decomposing influence upon this compound, an influence which may be counteracted by a body, such as oxygenated water, containing *antozone*.

But my object in thus somewhat prematurely introducing the subject to your notice is to enable those of your scientific readers who may have greater facilities and more leisure for the prosecution of the inquiry than I myself possess, to enter upon a subject the elucidation of which might be of great practical benefit. It would be for them to trace whether there exists any connection between the condition of the atmosphere with regard to ozone, and the amount of apparent stability in such compounds as the fulminates and gunpowder.

This investigation might possibly furnish us with the means of guarding against the fearful consequences of chemical action in explosive or highly combustible bodies. The recurrence of fearful casualties in connection with gunpowder is a subject of common observation. Bearing in mind that the combustion of gunpowder is simply a series of chemical combinations, any one of which is sufficient to occasion the others, and the extraordinary energy with which ozone acts upon oxidisable bodies, it becomes more than probable that the existence in the atmosphere of any considerable amount of ozone would greatly facilitate chemical action in the powder, thus occasioning its explosion under circumstances in which it would generally be harmless.

Desmond G. Fitzgerald.

27 Upper Berkeley Street, Portman Square.

INCENDIARY SHELLS FOR WARFARE.

(From the *Sun* of April 16.)

Some efforts having been recently made to deprive Captain Norton of the credit of being the author of the improvements which have been lately made in gunnery projectiles, we think it due to the gallant gentleman to publish the enclosed letter addressed to him by the son of General Sir William Napier, the celebrated historian of the Peninsular War, in his father's name:—

"Scinde House, Clapham, April 3, 1859.

"Dear Sir,—My father has been for more than a year now unable to walk, entirely confined to two rooms. He is only able to be lifted from one bed to the other, and continually suffering. In November and December he was seized with very dangerous illness, from which he only recovered so far as the immediate danger was concerned. For the last three weeks he has again been very ill indeed, and he is unable to move even a limb without assistance, and quite unable to write or attend to any business. But for this, he desires me to tell you, he should have written to you long ago to congratulate you, as he now does through me, on your merits being at last acknowledged, and on your being now generally allowed to be the real originator and inventor of the great improvements in gunnery projectiles. My father says, had this been acknowledged, and your inventions acted on years ago, much of the misfortunes in the Crimean war would have been avoided. It is with serious uneasiness he now considers that there are no men to use these improvements. Often has my father spoken of you and your invention to men, and they have answered slightingly until now that the tide has turned in your favour; yet five years ago, he says, they were as valuable as they are now.

"I remain, dear Sir, yours truly,

"Captain Norton. C. J. Napier."

(From the *Sun* of April 19.)

Sir,—In justice to Mr. Macintosh, I beg to correct an error which I perceive you made in your number of yesterday; and having given so prominent a notice to a letter sent to you relative to Captain Norton being congratulated by the son of General Sir William Napier (sent to Captain Norton at Sir William's request), "as being now generally allowed to be *the real originator and inventor* of the great improvements in gunnery projectiles," &c., I beg to state, in explanation, that although Captain Norton has amused himself (for some time past) by experimenting at Chatham with shells filled with liquid and other incendiary materials, he has done so *well knowing* that the inflammable materials he was using were not compositions of his own invention, but were those of Mr. John Macintosh, of Northbank, Regent's-park. Although Captain Norton was "*fully aware*" that he was experimenting with materials patented and invented by another inventor, he has not had the courtesy of explaining this fact, nor has he yet requested any of the periodicals or newspapers to correct the error they have all invariably committed, in ascribing the invention of the compositions he experiments on, when using incendiary shells, to him, whereas Mr. John Macintosh is the true and real inventor. I beg to add that both the "War and Admiralty Departments" have been fully cognisant, since 1853, prior to the last Russian war, and have made several official experiments with Mr. Macintosh's incendiary compositions for filling shells, which, although satisfactory, have not yet been adopted into the service, for reasons which the late Secretary of State for War, Lord Panmure, can best explain; he having, as you are already aware, "officially sealed-up" Mr. Macintosh's patent, No. 1774, during the continuance of the last Russian war, and then allowed Mr. Macintosh to obtain his patent "*after*" the war was concluded, and then refused to either purchase it or adequately remunerate him for this illegal seizure. The application for the "New Patent Law" sufficiently explains this fact, and further, that this "New Patent Law" has entirely originated from the result of Mr. Macintosh's ingenious and laborious inventions.

Trusting you will kindly give equal publicity to this statement,—I am, Sir, &c.,

April 17. Justice.

N.B.—Mr. Macintosh's specification, No. 1774, can be inspected at the Great Patent Seal Office, 25 Southampton-buildings, Chancery-lane.

SERGEANT WARRY'S IMPROVED GUN AND PROJECTILES.

The improved breech-loading cannon, invented by Mr. Warry, the armourer of the 3rd battalion at Chatham garrison, having been submitted, from time to time, to a series of trials, with the view of testing its efficacy, all with the most satisfactory results, the authorities have been communicated with in order to enable the inventor to ascertain whether it is the intention of the Government to take up the invention, and appoint a commission to superintend a succession of trials with the gun, in order that its superiority over all other breech-loading cannons now in use may be determined. Since the former accounts of the performances of this new weapon appeared in *The Times*, the inventor has effected another important improvement in it, which has the result of making the discharges even more rapid than before, the gun being now capable of discharging, with ease, 20 rounds per minute. This improvement is effected by a beautifully-contrived lever, placed on the side of the breech, which by one simple movement raises the cock of the gun, and opens the breech: the reverse movement entirely closing the breech, cutting the cartridge used, priming the nipple, and firing the gun all instantaneously—the effect of which is, that the cannon may now be discharged as rapidly as the charges can be inserted in the breech, as two simple movements are now all that is necessary to prepare the gun for being fired, and actually discharging it. The inventor has also effected an improvement in the balls used for breech-loading guns, for which he has applied for a patent. This improvement consists in the manner of coating the balls, the present lead and tin coating with which balls have hitherto been covered leaving a deposit in the gun which necessitates that the bore should be cleaned out after every few rounds have been fired, the Armstrong gun, for instance, requiring sponging after about every dozen rounds, and occasionally more frequently. To obviate this Mr. Warry has invented a chemical composition which he applies to the spherical balls used by him, and which answers its purpose so satisfactorily that after 50 rounds were fired the other day with these balls so coated, not the slightest fouling the gun could be detected, the breech, in consequence of the current of air admitted each time it was loaded, remaining as cool as at the commencement, while no expansion could be perceived. The inventor also states that by using his method a dozen balls can be coated for the expense now incurred in coating one on the old principle. Should the Government consent to take up the invention, Mr. Warry is prepared to apply his breech-loading principle to any of the metal guns now in use, which, at a comparatively small outlay, can be so adapted. It is a remarkable circumstance in connection with this invention that shortly after the account of this new weapon first appeared in *The Times*, the inventor was waited on by the agent of a foreign Government, and offered the most handsome terms to transfer his invention to that Government, or part with the model of his gun, both of which offers Mr. Warry, for obvious reasons, declined, not even allowing an inspection of his model.—*Times*.

Mr. J. Robertson has been reading a paper to the Manchester Statistical Society on the insalubrity of the deep Cornish mines and the physical degeneracy of the mining population. The Rev. E. Trollope has also delivered an interesting lecture at Stamford on the fens and submarine forests of Lincolnshire.

Belgian papers announce that a means of uniting steel and iron has been discovered, and that some rails have been made at the ironworks of Montigny-sur-Saumbre, of which the flange is in steel, and the body in iron.

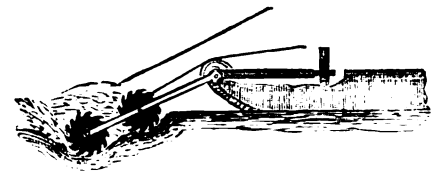
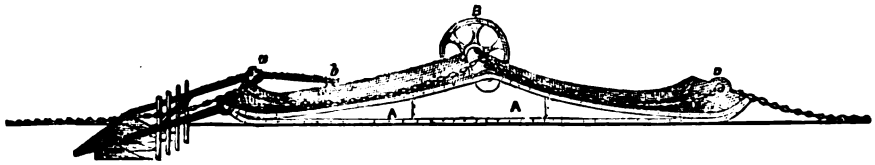
STEAM PLOUGHING.

By Captain J. H. Selwyn, R.N.

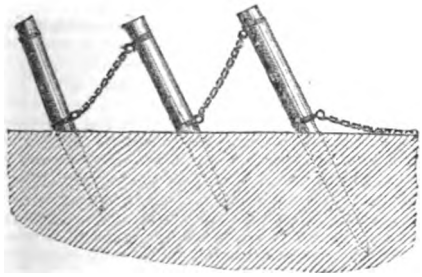
[We think it desirable, in view of certain movements now in progress, to publish the following letter, written two or three years since by Captain Selwyn.]

The novelty which it is believed is possessed by this invention chiefly consists in the placing of the motive power on a large flat surface of iron, which slides over the ground, drawn by a rope or chain, which, being fixed at either end or any part of the ground to be ploughed, passes over or round a windlass or roller, which roller being itself fastened to the bed or platform of iron, is set in motion by the steam-engine upon the platform.



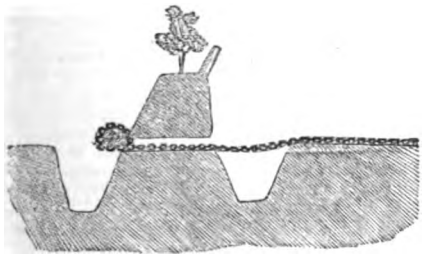


The ploughs or other means employed for disturbing the ground are fastened in a frame *a*, which projects over the hind part of the platform or boat, pressed into the ground by springs or other means at *b b*. The chain is fixed at both ends of the ground, but slack, so that a turn may be taken round the windlass (if it be not found preferrable to use a bedded wheel, as in the steam bridges) before replacing it, after the engine is "embarked." The mode of fastening the chain, and which is, I believe, new as regards its application, is by stakes or posts driven in as under. By this means any



resisting power required is easily obtained, at a far less expense and trouble than with anchors, *i.e.*, where trees or other natural fixed points do not present themselves.

Another mode by which this may be effected, where the contiguous fields are in the same occupation, is by making holes at given distances through the bank. A piece of timber used as a "toggle" may then be easily applied.



As soon as the chain becomes slack *behind* the engine the posts or other means of attachment at that end may be shifted to the next "land," and on the engine arriving at the end of the field it will be turned, by unshackling the chain and passing it in again through the hole in front Some guide or pivot forced into the ground must also here be used to cause the machine to turn short on to the next "land."

It is also proposed, as part of this invention, to use, in light soils or wherever practicable, a totally different means of disturbing the soil.

This is done by the use of two or more cylinders set with teeth or claws, which are set in the frame instead of the ploughshares, and which will then, on being set in rapid motion, scratch out the soil and throw it behind. The lower cylinder (neither of which should have a *diam* of more than six or eight inches) being driven at the highest velocity, and consequently throwing the subsoil to the top. Probably in this a means (as revolving brushes) of clearing the teeth from stubble, &c., would be necessary.

J. H. Selwyn.

Note.—No objectionable pressure on the land need be anticipated. The sledge would be about 12 ft. by 8, or 96 square feet; and, taking the weight at 3 tons, there would be only about 70 lb. on each square foot. A man walking over the ground, say weighing 160 lb., would give considerably more.

MR. VARLEY'S PAPER ON THE TELEGRAPH.

Gentlemen,—In the published report of my paper read before the Society of Arts, "On the Practical Bearing of the Theory of Electricity in Submarine Telegraphy," a few errors have occurred—most of them, however, are of minor importance. Perhaps you would be kind enough to correct the following; as, if uncorrected, it may lead some of your readers into error. The weight of the conducting core of the Atlantic cable is stated in the report to have been 63 lb. to the mile—it should have been 93 lb.; and the rough estimate of the value of a conductor of twice the diameter should be £19, not £16.—I am, Sir, your obedient servant,

S. Alfred Varley.

7 York Place, Kentish Town, April 18, 1859.

THE REPEAL OF THE PAPER DUTY.

Those of our readers who enjoy and benefit by the press of this country will, we trust, give proper heed to the following earnest appeal:—"To the Electors of the United Kingdom."—

"Gentlemen,—Your suffrages are being solicited by candidates for the honour of representing you in Parliament. Let us urge you to press upon them at the hustings, the question of the Repeal of the Paper Duty. The tax on paper shuts out light from the minds of working men, and bears, therefore, on the question of Reform; it weighs on all classes of manufactures; as a source of revenue it is a delusion; it aggravates pauperism, and tends, by narrowing the area of productive labour, to cripple legitimate consumption, and to retard social progress; it hinders the spread of a wholesome literature among the people, and absorbs a considerable portion of the money contributed to the great publishing societies established to secure the diffusion of religious and useful knowledge.

"The House of Commons condemned it, last June, as an *impolitic tax*, and it would be the duty of Parliament to make up for any *temporary* deficit that might result from its immediate abolition.

"The Committee of the Newspaper and Periodical Press Association for obtaining the Repeal of the Paper Duty, urge you to secure pledges from candidates, that, in the event of their being elected, they will give their votes for the repeal of this most injurious impost. Signed, on behalf of the Committee.—John Cassell, Chairman, Henry Vizetelly, Hon. Sec. Peele's Coffee House, Fleet Street, London, April 14, 1859."

NOTICES.

The Mechanics' Magazine will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

The demand for Mr. E. J. Reed's paper—

On the Modifications which the Ships of the Royal Navy have Undergone during the Present Century, in respect of Dimensions, Form, Means of Propulsion, and Power of Attack and Defence,"

has been so great that the Journal of the Society of Arts, the Mechanics' Magazine, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Law Cases.

Equity Court, April 16.—(*Before Vice-Chancellor Sir W. P. Wood.*)

HART v. DACOSTA.

This case came on upon a motion to restrain the defendant from vending a gas regulator alleged to be an infringement of a patented article invented by the plaintiff. The plaintiff's regulator consists of a small conical chamber about an inch and a half in length and half an inch wide at its widest part. This chamber is attached to the gas pipe, and into it is secured the ordinary steel pipe or burner from which the gas issues. In the interior of the chamber there is a small apparatus, consisting of two round pieces of perforated metal, held parallel to each other, but not fixed by a small bolt of wire, and enclosing between them two or three layers of felted wool. At the top of this piece of apparatus a piece of loose wool is inserted in the chamber. The action of the invention is this—when the gas enters the chamber in order to pass out at the burner it must force its way through the bottom perforated plate, then through the felted wool, next through the top plate, and finally through the loose wool. The greater the pressure of gas at the main the greater will be the force with which the lower perforated plate presses the felted wool against the upper plate, and so the more difficulty will there be in the gas escaping at the burner. It will be seen, therefore, that if the regulator is properly adjusted, whatever may be the pressure at the main, the force with which the gas escapes from the burner will always be the same. The loose valve is to act as a purifier only. The defendant's invention consists of a conical chamber like the plaintiff's, but in the interior of the chamber there are no perforated plates or wool, but shreds of steel or iron only. In its action it operated somewhat in the same way as the plaintiff's. The plaintiff was willing now to take the usual order for the motion to stand over, with liberty to bring his action.

Mr. Rolt and Mr. H. Palmer were for the plantiff; Mr. Hallett was for the defendant.

The Vice-Chancellor thought that there was certainly a case to go to trial, and directed the motion to stand over accordingly.

Court of Queen's Bench, Westminster, April 16.—(*Sittings in Banco, before Lord Campbell and Justices Erle, Crompton, and Hill.*)

BETTS v. MENZIES.

This was an action brought to recover damages for the infringement of the plaintiff's patent for the manufacture of what is termed "Betts's Metal." The trial took place before Mr. Justice Erle, at Westminster, at the sittings after last term, and after occupying several days resulted in a verdict for the plaintiff.

Mr. Mellor, Q.C., now moved for a rule for a new trial, upon the ground that the verdict was against the weight of the evidence. There were also several points of law reserved for the opinion of the Court.

Lord Campbell said the learned counsel might take a rule to show cause.

Digitized by Google

NALDER *v.* CLAYTON AND ANOTHER.

Mr. Knowles, Q.C., moved for a rule calling upon the plaintiff to show cause why the verdict found for the plaintiff should not be set aside, and entered for the defendant, pursuant to leave reserved. The action was brought to recover damages for the infringement of the plaintiff's patent, for improvements in machinery for winnowing and dressing corn; and the question to be determined turned entirely on the models, with the specification and description. The learned counsel, therefore, asked the Court to hear the description of the models in their lordships' private room.

Lord Campbell said he should heartily concur in that suggestion, if no objection was made on the other side.—Rule *nisi* granted.

Our Weekly Gossip.

We took the trouble to go to 55 Piccadilly on Monday last to inspect the wonderful heating apparatus of the Rev. H. J. Newcome, mentioned in our "Gossip" of last week. The whole mystery consists in the employment of a number of thin metal flues or casings, through which the products of combustion have to pass before they escape by the chimneys. That is all!

Mr. Clifford's boat-lowering apparatus did good service last week. A serious collision took place off Lizard, by Her Majesty's steamship Perseverance coming in contact with the British barque Ava, Captain Graham, from Cardiff, for Gibraltar, which almost immediately foundered. The crew of fifteen were saved by the boats of the Perseverance, which were fitted with Mr. Clifford's apparatus, but for which every soul would, in all probability, have perished.

The country papers are, we see, doing justice to the true founder of the London Mechanics' Institute. The *Leeds Intelligencer* says:—"It has been popularly believed that Dr. Birkbeck was the founder of this institution, and we think we have more than once seen it asserted by leaders of mechanics' institutions in Yorkshire that he was. The MECHANICS' MAGAZINE has done honour to whom honour is due."

A French astronomer, the Padre Secche, asserts positively, and without the least suspicion of mistake or illusion, that the third satellite of Jupiter is not of a spherical, but an elliptic figure; that it has marks upon it, and that its rotation is not in the plane of its orbit. We met with this statement first in the *Leeds Intelligencer*.

Dr. J. Forbes Watson, A.M., M.D., Reporter on the Products of India, desires to make known that an attempt made last year to grow "gram"—the great horse food of northern and western India—in this country succeeded in a few cases. He is now anxious to have the experiment repeated this season on a more extended scale. A piece of ground well sheltered from north and east winds will be required, and should any of our country readers feel disposed to give this important pulse a trial he will be happy to send them some. He may be addressed at the India Office, London, E.C.

On Friday evening the Lord Mayor and the Lady Mayoress entertained a distinguished company of learned and scientific guests at the Mansion-house, to meet the President (Mr. Glaisher) and Council of the Blackheath Photographic Society. There were a large number of eminent men present, and a brilliant assemblage of ladies on this interesting occasion. The guests, to the number of 500, commenced assembling shortly after 8 o'clock.

One of the boats of the Royal National Life-boat Institution did good and gallant service at the Goodwin Sands as our article in favour of the Society was passing through the press on Friday last.

M. Niklès has communicated to the Academy of Sciences, Paris, his researches on a new mineral recently found at Plombières, and which he calls *saponite*. Its appearance is a soapy-feeling stone, of a whitish colour sometimes veined with blue, it can be cut and scraped with a knife, and will crumble between the fingers; its cohesion is destroyed in cold water, when it becomes a paste, but does not dissolve. M. Niklès pronounces it to be a hydro-silicate of alumina.

His Royal Highness the General Commanding-in-Chief, attended by Colonel Tyrwhitt, Aide-de-Camp, went down to Woolwich, on Tuesday morning, and witnessed the trial of a new method of lubricating the barrels of the army rifles, proposed by Mr. Whitworth. Mr. Whitworth personally directed the trials with one of his own rifles and one of the Enfield large bore. The target stood at a distance of 500 yards from the firing station, and after firing a number of rounds, the distance was increased to 800 yards. The method was perfectly successful.

Mr. F. A. Abel, the chemist to the War Department, has been engaged at Chatham in making some further experiments for the purpose of demonstrating the manner in which charges of gunpowder may be fired by means of a magnetic agency, discovered by Mr. Abel, which is likely to supersede the voltaic battery at present used for submarine and other explosions.

A couple of sample gun carriages and slides are in course of construction in the Royal Carriage department, Woolwich, on a perfectly new principle, from designs submitted to Colonel Tulloh, the superintendent, by Sir William Armstrong. One of the carriages is intended for a 40-pounder Armstrong siege gun, for land service, and the other to work a 32-pounder ship's gun. The slope of the carriage for the reception of the gun is on an acclivity of 22 degs., which will considerably counteract the heavy recoil usually experienced with so much inconvenience, especially on board ship, where it has sometimes been found expedient to erect an exterior scaffolding for the purpose of loading and cleaning out the gun, so as to afford space for the recoil under the confined dimensions of a ship's decks.

It seems that the great organ placed in the new Leeds Town-hall is the third, as to size, in England, the number of pipes being 6,150, while it is larger, with one exception, than any on the continent. The organ is supplied with wind by hydraulic engines, patented by Mr. D. Joy and Mr. W. Holt, of Leeds. Five of these machines attached to a similar number of bellows, and conveying, by means of twenty-seven reservoirs, wind to the various parts of the instrument, are placed in the basement of the building.

Mr. M. Fryer has been lecturing on colliery machinery at the Bristol School of Mines. Mr. Fryer argued that the progress and success of almost every description of work depended in the present times upon the skilful use of machinery. Machinery advantageously employed at the surface of some of the best conducted and most profitable collieries, is at others entirely neglected. Proper tipping machines, screens, spouts, and self-acting apparatus for re-raising the small coal to a level from which it can be run down spouts into carts and waggons may at any rate partially obviate waste of time and labour. Self-recording weighing machines would be an invaluable addition to the surface machinery; and self-acting inclines and steam-engines for the underground transport of coal are true economy underground. Mr. Fryer does not doubt that in course of time we shall have practical and economical coal-cutting machines; and he considers that the methods which have in most cases been adopted for raising water from the deep workings of mines to the bottoms of the shafts are admissible of very considerable improvements; indeed, in machinery generally there is, he thinks, no standing still. Pounds, shillings, and pence considerations should never, however, be overlooked.

At Liverpool, by order of the Dock Board, certain alterations are to be made in the locks leading to the Leeds and Liverpool canal through the Salisbury and Collingwood docks. Two electric time balls are to be placed in an elevated position along the line of docks, one on the summit of the Victoria tower, and one on the south-west corner of the Albert warehouse; the cost is stated at £250. At the last meeting of the board a letter was read from the manager of the Woodside Ferry stating that in order to facilitate the carriage of loaded carts and carriages across the river at all times of the tide, the commissioners have under consideration the construction of steam-vessels on the American principle. The board resolved—with reference to another observation from the Birkenhead commissioners, that they could not effectually carry out their principle unless the landing stage at Woodside was constructed with this object and one of the landing stages on the Liverpool side altered—that every possible facility should be given. Mr. Hartley has been directed to prepare plans and report upon the best station for a coal dock and graving dock at Birkenhead.

Several journals have announced that a new gun-boat is being constructed at Bordeaux, 225 feet long, and capable of carrying 10 guns. The fact is not so. It is not a gun-boat that is being constructed at Bordeaux, but a model of a boat for landing troops, of which the idea originated with the Emperor, and which is intended to replace the old barges, which were so inconvenient. This new boat is sufficiently capacious to land 2,000 men, and will be armed with 14 swivel guns for the purpose of defending the landing. The Minister of Marine has appointed M. Duperrré, his orderly officer, to the command of the gun-boat lately constructed at Bordeaux, and which is at this moment on the Seine at Paris. We make these statements on the authority of the *Times'* Paris correspondent, who also informs us that the Emperor inspected a new kind of gun-boat at Grenelle on Friday last. He was accompanied by Major Treuil, of the artillery, attached to the Museum of Artillery in Paris. Experiments are to be made with the gun in this boat on the river between Paris and St. Cloud, for which purpose a provisional polygon is to be prepared, and great precautions adopted against accidents.

It has fallen to the lot of almost every person to have had in his possession, at one time or another, a silver or gold coin which was hollow, or cracked on the edge, and it is astonishing to think of the fallacy existing in the public mind as to the cause of this defect. The prevailing belief is, that at the Mint all coins are manufactured in halves, and that through defective workmanship, or wear and tear, some of them in time show symptoms of weakness, and become "cracked." Another supposition is, that gamblers have been unsuccessfully endeavouring to separate heads and tails for the purpose of uniting two heads and two tails, and thus forming cheating coins. This latter operation has indeed been performed, such pieces having fallen, we believe, into the hands of the authorities of the Mint. But neither of these theories as to cracked coins is the correct one. The evil arises in a way which we will briefly attempt to describe. All legitimate coins in this kingdom are made from cast bars of metal. At the Tower Hill establishment there are orthodox sizes for these bars, proportioned to the character of the coins to be produced from them. At a future time these sizes may be given exactly. That for sovereigns is about 26 inches long by about 1½ inches square. The bars are cast in vertical moulds of iron, fitted together in halves for the purpose of releasing the bars of gold. On filling the moulds from the crucibles, it will be comprehended at once by our readers, that in cooling there will be a natural subsidence in the centre of the upper end of the new made bar. Contact with the iron chills the outside of the bar first, and like the mercury in a barometer which is sinking, the gold is depressed in the centre. Such is the case, more or less, with all bars of gold or silver cast for coinage purposes. The lower end will be perfectly square as the bottom of the mould is, but the upper must be as we describe it. In this form the bar—for one will serve us in this explanation—is taken to the rolling mills. Here it is laminated between chilled rollers until reduced to nearly the required thickness for having punched out of it blank sovereigns. It will be observed that the hollow or upper end has been compressed to the riband-like thinness, as well as the square or lower ends, and it now exhibits, if closely examined, a crack on its edge. This, then, is considered a waste end, and a portion of it is cut off by means of a pair of shears, and returned to the melting pot. Sometimes, however, enough is not cut from the cracked riband to remove the entire defect, and it passes thus to the cutting-press room. Here the ribands are perforated from end to end by punches of the size of the sovereign, and if the hollowness has not been entirely removed by the shears, we shall have some few cracked sovereign blanks mingled with those that are perfect. Ringing boys are now employed to test the whole by dashing them—with as much rapidity as an expert drummer boy at the Tower beats "tattoo"—upon discs of polished iron. The sound pieces are musical—the unsound have "no music in their souls," and it is for the boys, by the aid of quick ears and eyes, to detect and put aside the defaulters. Boys are fallible, however, and they allow "dumb" pieces to escape occasionally. These pass on to be stamped on both sides and milled on the edge at a single blow, and the probability is, that the hollowness of their characters will only be discovered after some contact with the world, as in other cases, and then by the *counter* test of some suspicious shopkeeper, who pronounces them genuine though "cracked," and passes them into his till with pleasure.

The *Hampshire Telegraph* gives the following account of an experiment at the Gunboat Slipway at Haslar:—"On Thursday morning last a launch took place from this slipway, for the purpose of ascertaining in what space of time a boat could be taken into the harbour. The boat selected for this trial was the Cheerful, 2 (on board which the plan of fitting the boilers on cast-iron sleepers has recently been carried into effect), which had previously been placed on the incline for the experiment, with her steam up. The Commander-in-Chief, Admiral Bowles, Admiral Sir George Hope Grey, Flag-Captain Farquhar, Captain Gordon, and Commander Gardener arrived on the spot at twenty minutes past ten, and, everything having been previously placed in a state of readiness, the dogshoars were knocked away, and in a minute and a half the boat was fairly clear of the cradle. Her screw was set in motion at 10·30, and in five minutes she had steamed down as far as Haslar-bridge, where, in consequence of the abrupt turnings

Digitized by Google

of the channel, the different 'sets' of the tide, the height of water underneath the bridge, and the circumscribed space through which the Cheerful had to pass, the screw-propelling power was abandoned, and warping assistance had to be relied on. The clearing of the bridge amid an almost momentary change of orders, such as 'Hold on, aft,' 'Together by the bow, handsomely,' 'Helm a-port,' 'Steady by the bow,' 'Starboard helm—so,' &c., &c., entailed a waste of exactly twenty-five minutes, the boat finally clearing the bridge at 11 o'clock. Her screw was then again set in motion, and in eight minutes more she had run clear through the intricate channel of the creek. The result was regarded as highly satisfactory, for, deducting the time expended in getting her underneath the bridge, she would have perfected the trial required in about a quarter of an hour. The delay alluded to is one that must always occur whenever a boat either goes up to, or comes down from, the slipway; and until a swing bridge is substituted for that now in use, with the appliances for damming up the water, so as to render the launching operations easy at any time, the principal provision for ensuring the assistance of the boats on Haslar slipway will have been neglected. We consider the difficult task of warping the boat underneath the arch of the bridge to have been most skilfully performed, there being not a foot of space in depth to spare, with a similar contraction at the sides, the tide at nearly a quarter ebb, and a strong breeze from the south. Since our last visit to the sheds several alterations have been made, which are designed to ensure greater privacy in the working of the machinery; a second cradle is also in course of construction, which, when completed, will materially facilitate the launching of boats whenever the services of more than one shall be called into requisition at the same time."

The *Photographic News* says,—"The question whether paper coloured green with arseniate of copper (Scheele's green) used in papering the walls of rooms gives off poisonous emanations is one which recent experiments have decided in the affirmative; and this, too, in quantities which render its use positively dangerous. At the same time the beauty of the colour, and the relief it affords to the eyes, makes the continued use of this coloured paper desirable. A very simple means of preventing these arsenical emanations may be found in the use of varnish; this, and the coating of size which precedes it, effectually isolating it from contact with the atmosphere.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated March 12, 1859.

636. J. Thornton, of Liverpool. Improvements in machinery for the manufacture of bricks, tiles, and other similar articles.

Dated March 16, 1859.

658. C. Parker, of Dundee, Engineer. Improvements in looms for weaving.

666. E. Anscombe, of Pimlico, Joiner. An apparatus for taking an accurate delineation of any view or object in open air or otherwise.

Dated March 17, 1859.

676. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Treating barley so as to obtain new alimentary substances therefrom. A communication from P. Marmay, of Riom, France.

682. J. Donat, of Paris. Improvements in apparatus used with matches for obtaining instantaneous light.

Dated March 19, 1859.

700. J. W. Hart, of St. Mary-Axe, Gentleman. An apparatus for the destruction of flies and other insects. A communication from F. Barnett, of Paris.

Dated March 22, 1859.

722. W. Weild, of Manchester, Machinist. Improvements in machinery and arrangements for coating slips, sheets, rods, and bars of metal, and laths, rods, and boards of wood, and similar articles formed of other substances, with paints, varnishes, and other like preparations, and drying the same.

727. D. L. Banks, of Kennington, Engineer. Improvements in suspension rail or road ways, and in machinery or apparatus connected therewith.

734. J. Macintosh, of North Bank, Regent's Park, Gentleman, and G. Rhodes, of Regent-st., Major. Improvements in tents and such like coverings for shelter against the weather.

Dated March 29, 1859.

778. T. Carr, of Bebington, Chester, Artificial Manure Maker. Improvements in machinery for disintegrating artificial manures, and various other substances.

779. C. L. Roberts, of Clerkenwell. Improvements in cigars.

781. J. W. Kelly, Civil Engineer, of Ennis, Ireland. Improvements in gas burners.

782. E. de Caranza, of Paris, Engineer. A new system of gas lighting through new apparatuses and matters richer in gas than pitcoal.

783. E. N. Norminton, of Camden Town. The cleansing and re-manufacturing of old used dirty railwaygrease for the manufacturing of new railway grease, for the cleansing and re-manufacturing of old used cotton waste, tow, or any textile fabrics, and for the purifying of oils or any fatty matter.

785. R. Scarle, of Woodford Wells, Gentleman. Improvements in apparatus used for transmitting signals by electricity for telegraphic purposes and in the construction of telegraphic cables.

786. I. Spight, of Glandford Briggs, Lincoln, Iron Founder. Improvements in horse hoes.

787. T. Taylor, of Vere-st., Chemist. Improved means of giving increased strength to paper.

788. H. P. Burt, of Charlotte-row, Mansion House. Improvements in apparatus for preparing and preserving timber.

789. H. Moss, of Somers Town, Boot Maker, and T. West, of Jewin-st., Machinist. A machine for the cutting of leather for every purpose, and cutting cloths, linen, and other fabrics and materials.

Dated March 30, 1859.

791. J. H. Linsey, of Cheapside. Certain improvements in binding or covering books.

793. W. V. Edwards, of Swindon, Wilts, Iron-founder. Improvements in the construction of ways and apparatus to facilitate the conveyance of mails, goods, and passengers.

794. G. T. Bousfield, of Brixton. Improvements in preventing explosions in steam boilers. A communication from F. Marchal.

795. T. D. Shipman, of Toronto, Canada. Improvements in apparatus for stamping and printing. Partly a communication.

796. H. Jefferies, of Birmingham, Button Maker. Improvements in castors for furniture.

797. J. Cartwright, of Shrewsbury, Agricultural Implement Maker. An improved implement for crushing clods and pulverizing the surface soil, also convertible into a press wheel roller.

798. C. P. Coles, of Southsea, Hants, Captain R.N. An apparatus for defending guns and gunners in ships of war, gun boats, and land batteries.

799. W. Gossage, of Widnes, Chemist. Improvements in the manufacture of certain alkaline silicates, and in the production therefrom of liquor silicis or liquid flint.

800. A. V. Newton, of Chancery-lane. An improved governor for marine and other steam engines. A communication.

801. W. Smith, of King-st., Smithfield, and E. Smith, of Hamburgh, Gas Meter Maker. Improvements in means or apparatus for the purpose of regulating the flow or passage of fluids.

Dated March 31, 1859.

802. J. Lacy, Cotton Spinner, and S. Simpson and H. Smith, Managers, all of Walsden, near Todmorden. Certain improvements in machinery for preparing and spinning cotton, and other fibrous materials.

803. C. Pickering, of Tonbridge. Improved apparatus for brewing.

804. R. C. Ross, of Glasgow, Engineer. Improved apparatus for cultivating land.

805. T. Ivory, of Edinburgh, Advocate. Improvements in rotary engines.

807. A. Morton, of Kilmarnock. Improvements in sextants or quadrants for nautical purposes, and which are also adapted to the measuring of altitudes or angular distances.

809. J. S. Bateson, of Mayfair, Barrister-at-Law. Improvements in generating steam and in the apparatus employed therein.

810. F. Morton, of Liverpool, engineer. Improvements in the construction of fences and the posts or pillars for the same, parts of which improvements are also applicable to the construction of gate posts or poles for telegraph purposes or for signal posts.

811. W. E. Newton, of Chancery-lane. Improvements in mills for cleaning rice. A communication.

812. A. V. Newton, of Chancery-lane. Improvements in the construction of steam boiler and other furnaces. A communication.

Dated April 1, 1859.

813. D. K. Clark, of Adam-st., Adelphi, Civil Engineer. Feed water heating apparatus.

815. I. Sigismund, of Hull, Dentist. Certain improvements in the manufacture of artificial teeth, and in the apparatus connected therewith. Partly a communication.

816. R. A. Brooman, of 166 Fleet-st., London, Editor of the Mechanics' Magazine and Patent Agent. Improvements in machinery for solidifying, pressing, and moulding. A communication from F. Dehaynin, of Paris.

817. R. A. Brooman, of 166 Fleet-st., London, Editor of the Mechanics' Magazine and Patent Agent. A new preparation of indigo for dyeing. A communication from Messrs. Depoully Frères, of Paris.

819. W. E. Newton, of Chancery-lane. An improved process of manufacturing sulphate of lead, carbonate of lead, nitrate of potash, and sulphate of soda. A communication.

820. J. J. Davis, of Clerkenwell, Die Sinker. An improved pad, applicable for inking, damping, and other like purposes by hand.

821. W. Tod, of Glasgow, Marine Engineer. Improvements in marine steam engines.

822. Y. Thomas, of Paris. An improved propeller for ships, vessels, boats, and water-wheels.

Dated April 2, 1859.

823. J. Desmet-Séaut, of Mons, Belgium, Mechanician. An improved gas burning and lighting apparatus.

825. J. Hall, of Chelsea, Engineer, and J. S. Sparkes, of St. John's Wood, Gentleman. An improved application of machinery for the purpose of hoisting, lowering, pulling, or drawing weights.

827. S. Desborough, of Noble-st., City, Agent. Improvements in making up needles, steel pens, and other small articles for sale.

829. W. Mather, of Manchester, Druggist. An improved apparatus for catching and destroying flies and other insects.

831. M. Scott, Parliament-st., Westminster. Improvements in diving apparatus.

833. T. Richardson, of Hartlepool, Engineer, and G. W. Jaffrey, of the same place, Engineer. Improvements in the arrangements and construction of harbours of refuge, breakwaters, sea walls, or barriers, and other like structures.

Dated April 4, 1859.

835. F. Potts, Tube Manufacturer, and R. Brough, Engineer, both of Birmingham. Certain improvements in the manufacture of calico printing rollers or cylinders, also in the machinery and apparatus for performing certain parts of the same, and which said apparatus are also applicable, separately or conjointly, to the manufacture of parallel and other metallic tubes, and the rolling of the metal for the same or other purposes.

837. C. F. Kirkman, of Argyl-st., Gentleman. Protecting telegraph wires, and in using them for subterranean and submarine purposes.

839. W. Brown and C. N. May, of Devizes, Engineers. Improvements in hay-making machines.

841. W. E. Newton, of Chancery-lane. An improvement in ladies' hooped skirts. A communication.

843. C. Russell, of Stubbers, near Romford, Esq. An improvement in the working of marine engines.

845. D. B. White, of Newcastle-on-Tyne, M.D. Improvements in arranging ships and other pumps.

847. D. Sowden, of Bradford, Jacquard Machine Maker. Improvements in Jacquard machines employed for weaving figured goods or fabrics.

Dated April 5, 1859.

849. G. Haseltine, of Southampton-buildings. Improvements in sewing machines.

851. L. Brierley and H. Geering, of Birmingham, Manufacturers. A new or improved method of ornamenting metallic bedsteads and other articles of metallic furniture.

853. G. F. Chantrell, of Liverpool, Furnace Engineer, and E. Dutch, of the same place, Commercial Traveller. Improvements in the apparatus for regulating the quantity of water to be used for the flushing of water closets and other purposes.

855. J. Hetherington, of Manchester, Machinist, and T. Webb, and J. Craig, of Tutbury, Cotton Spinners. Improvements in machinery or apparatus for spinning and doubling cotton and other fibrous materials.

857. N. Libotte, of Paris, Mechanician. An improved safety apparatus to be applied to cages in the drawing of coals.

Dated April 6, 1859.

859. T. P. Luff, of Shepton Mallet, Somerset, Estate Agent. Improvements in cheese vats.

861. J. A. H. Ballande, of Paris, Gentleman. An improvement in the preparation of writing-paper, and ink to be used thereon.

863. J. Rogers, of Queen-sq., City, Rope Maker, and E. J. Tweed, of Castle-street, Falcon-sq. Improvements in coating conducting wires used for electric telegraphic purposes.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

860. I. Adams, of Massachusetts. An improved tubular chain cable guide for vessels' bulwarks. A communication from A. S. Phillips, of Boston. Dated 6th April, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, April* 19, 1859.)

2793. D. B. White. Gauges.
2797. J. E. Boyd. Taps, valves, &c.
2800. J. Whitley and T. Kitchenman. Hot pressing.
2803. J. G. E. Larned. Steam fire-engines.
2806. W. Burness. Pumping liquids.
2808. J. Ferrabee and F. H. England. Carding, &c.
2810. G. F. Chantrell. Animal charcoal.
2811. C. de Cappot and A. Jarriant. Hydraulic counter.
2817. C. M. Westmacott. Permanent way.
2818. H. Meidinger. Electric batteries.
2826. J. Stewart. Pianofortes.
2831. B. Lauth. Rods and shafts.
2833. J. Lightfoot. Printing yarns.
2837. C. Hodgson. Peat.
2838. W. Beardmore. Steam boilers.
2840. G. W. B. Kiallmark and W. T. Timewell. Cements.
2842. J. B. Guthrie. Overshoes.
2843. S. Dudgeon. Gas regulator.
2850. J. A. Carruthers and T. Blackburn. Guiding warp threads.
2852. L. C. V. Von. Elastic beds.
2854. J. E. Boyd. Candlesticks, lamps, &c.
2858. J. Ferrabee. Steam engines.
2860. E. Bow. Pumps.
2870. P. C. N. J. Viellard-Migeon. Screws, rivets, &c.
2882. A. and F. J. Stokes. Screws.
2884. J. H. Selwyn. Paying out cables.
2899. J. Aitken and J. Brooks. Looms.
2901. A. Mitchell. Registering the speed of Engines.
2904. E. Weber. Dyeing.
2916. A. S. Beliard. Pumicing felts, &c.
2925. W. Spence. Granaries. A communication.
2927. E. Green. Tables.
2939. J. T. P. Newbon, T. Smith, and J. Brown. Moving weights.
3007. J. H. Johnson. Steel. A communication.
114. F. J. Manceaux and E. N. Viellard. Firearms and cartridges.
317. A. Allan. Locomotive steam engines.
434. W. Horstmann. Telegraph cables.
495. S. R. Samuels. Twist lace machines.
496. S. Russell. Handles.
538. J. Kershaw. Weaving.
582. F. W. Parker. Sewing machines.

651. B. Rider. Hats, caps, &c.
670. H. Bessemer. Crank axles.
775. A. V. Newton. Furnace. A communication.
777. A. V. Newton. Annealing. A communication.
809. S. S. Bateson. Generating steam.
819. W. E. Newton. Sulphate of lead, carbonate of lead, &c. A communication.
821. W. Tod. Marine steam engines.
839. W. Brown and C. N. May. Haymaking machines.
849. G. Haseltine. Sewing machines.
860. I. Adams. Chain cable guide. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 16, 1859.

2327. J. Smith.
2328. E. Walker.
2329. J. Whitworth.
2331. J. Owen and H. Duckworth.
2332. A. Allan, T. Whimster, and R. Gray.
2405. T. Railton.
2435. C. Perley.
2465. C. Mather.
2513. A. V. Newton.
2529. A. V. Newton.
2685. E. Dixon and J. Fisher.
2695. J. Tangye.
2907. T. S. Woodcock.
267. J. Marino.
459. A. R. de Normandy.

Sealed April 18, 1859.

2339. W. Riddle.
2341. R. D. Clegg.
2344. T. Twells.
2345. J. Wainwright.
2346. S. T. Clarke.
2348. J. and S. Marland.
2351. J. M. Napier.
2361. J. and W. Bagnall.
2362. A. Shaw.
2363. R. Waller.
2366. E. and E. Palmer.
2379. T. and J. Ashworth.
2380. W. Craddock and J. White.
2403. J. Westerby.
2429. G. Davies.
2434. E. Maynard.
2412. R. C. Smith.
2461. J. Oxley.
2481. H. N. Penrice.
2503. J. S. Dawes.
2529. J. and W. Lees.
2532. M. Benson.
2538. T. F. Cocker.
2540. J. G. Martien.
2543. M. N. Mills and N. Sidebotham.
2561. A. Dick.
27. C. B. Blyth.
365. J. Crossley.
374. J. Young.
409. T. Hunt.
413. J. Copcutt.
439. J. Breeden.
440. J. Eason.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

876. R. S. Newall.
879. R. B. Lindsay.
882. P. Robertson.
889. S. C. Lister.
895. H. F. Forbes.
916. J. H. Johnson.
959. A. S. Vimont.
963. C. Nickels and J. Hobson.

LIST OF SPECIFICATIONS, &c.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 1980, 1993, 2008, 2033, 2034.
BOILERS AND THEIR FURNACES, 1977, 2032, 2051.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 1990, 1994, 2010, 2023, 2026, 2044, 2045, 2055.
SHIPS AND BOATS, including their fittings, 2027, 2031, 2039, 2042.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 1999.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 1951, 2004, 2007, 2056.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 1986, 2000, 2012, 2014, 2015, 2024, 2028, 2035, 2046, 2047, 2049, 2052, 2054.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2021.
LIGHTING, HEATING, AND VENTILATING, 1978, 1983, 1991.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 1979, 2002, 2003, 2006, 2017.
METALS, including apparatus for their manufacture, 1988.
CHEMISTRY AND PHOTOGRAPHY, 2018, 2021, 2036.
ELECTRICAL APPARATUS, 2013.
WARFARE, 1982, 1984, 2009, 2022, 2050.
LETTER PRESS PRINTING &c., 1992, 1996, 2016, 2025.
MISCELLANEOUS, 1985, 1987, 1989, 1995, 1997, 1998, 2001, 2004, 2005, 2011, 2013, 2020, 2029, 2030, 2037, 2338, 2040, 2041, 2043, 2048, 2053, 2057.

1977. J. H. JOHNSON. *Improvements in the prevention of steam-boiler explosions.* (A communication.) Dated August 31, 1858.

A complete specification of this invention was filed with the application, and an abridgement of it was published at page 621, No. 1846, of the MECHANICS' MAGAZINE (Old Series.) *Patent completed.*

1978. A. V. NEWTON. *An improvement in gas burners.* (A communication.) Dated August 31, 1858.

This consists in the application to "fish-tail" gas-burners of a cap or cover of a peculiar construction, whereby, with a small consumption of gas, a large and brilliant flame is produced. *Patent completed.*

1979. W. ROSE. *An improvement or improvements in piling or combining metals to be used in the manufacture of arms and cutlery, and for other similar purposes.* Dated August 31, 1858.

The object here is to produce an ornamental effect on the surface of the metal, which effect shall run through its entire body. The patentee combines together rods of iron and steel, or the action of such rods being of any figure he pleases, that, when united by heating and rolling, the mass or bar presents in its cross-section a chequered appearance. This bar may afterwards be twisted, and, as every turn of each twist will vary the patttern, an endless variety of ornamental lines may be produced upon the surface, and this effect will be still further diversified when the metal is intended to be worked up into twisted gun or pistol-barrels by the very process of twisting or coiling the metal. *Patent completed.*

1980. A. V. NEWTON. *Improvements in air engines.* (A communication.) Dated August 31, 1858.

The inventor connects the working and supply pistons to the crank of a fly-wheel shaft, by a system of levers, rock shafts, and connecting rods, of such a nature that an alternating accelerated and retarded reciprocating movement will be imparted to the two pistons capable of effecting the cooling of the working cylinder, and at the same time to produce motive power. Separate supply and working cylinders are so combined, and the pistons so moved, that the loss of temperature which attends the increase of bulk of the heated air during the outward movement of the working piston shall be made good by a process of reheating the air during its passage from the supply to the working cylinder. *Patent completed.*

1981. P. D. MARGESSON. *Improvements in treating sugar canes, and other canes containing saccharine matter, in the preparation of food for animals, also in manufacturing sugar, and worts, or wash, for brewing, distilling, and vinegar making, and in applying the resulting fibre in the manufacture of paper.* Dated August 31, 1858.

Here the cane is, as soon as ripe, cut into thin slices, and then dried by the sun in the open air. The dried cane is then reduced to a fine powder, and the powder is made into cakes by pressure. *Patent completed.*

1982. W. PURSALL. *Improvements in the manufacture of percussion caps.* Dated September 1, 1858.

The caps having been charged with the detonating composition, the powder is dropped into the same through perforated plates. The powder in each cap is then subjected to such pressure as equally to coat the surface of the detonating composition therewith, thus rendering the coating impervious to moisture, and protecting the detonating composition from injury resulting from exposure to damp. *Patent abandoned.*

1983. W. PHELPS. *Improvements in wet gas meters.* (A communication.) Dated September 1, 1858.

This consists in the use in wet gas-meters of an aqueous solution of deliquescent metallic and earthy salt or salts employed constantly neutral, by the pressure of a base or carbonate of such salt or salts. *Patent abandoned.*

1984. W. HOBBS. *Improvements in ordnance and warlike projectiles to be used therewith.* Dated September 1, 1858.

This consists in making portable guns capable of being used either as ships' guns, siege guns, field pieces, or long range guns, and when required for easy and speedy transit they can be taken apart, and each portion conveyed separately. *Patent completed.*

1985. J. SLOPER. *Improved means of and apparatus for indelibly crossing or marking bankers' cheques, drafts, documents, or other things, with a view of preventing erasures or fraudulent dealings therewith.* Dated Sept. 1, 1858.

This consists in forming any required crossing, word or words, letters or marks, by a series of perforations, punched in and through the cheques, drafts, &c., and so grouped as to represent the required crossing word or words, letters or marks. *Patent completed.*

1986. H. C. JENNINGS. *Improvements in the manufacture of artificial parchment, and converting the same into leather.* Dated September 1, 1858.

The inventor exposes fish to the action of dilute solutions of soda ashes, crystallized soda of commerce, or carbonate of potassa, after which to a solution of hydrochloric acid. The mass is pulped and saturated with a weak solution of bichloride of mercury, after which it is formed into sheets by the ordinary means, and then rolled or pressed to equalize the surface. To convert the parchment into leather he uses solutions of oak bark, terra japonica, or any of the substances employed by tanners. *Patent abandoned.*

1987. W. WARNE. *Improvements in the construction of elastic pavements and linings for walls, and in the manufacture of elastic mats, brushes, and pads for packing furniture.* Dated September 1, 1858.

Here tubes or hollow cells are used, made of india-rubber or india-rubber and its compounds rendered permanently elastic by sulphur, or sulphur compounds, and heat. *Patent completed.*

1988. A. V. NEWTON. *Improvements in the manufacture of alumina.* (A communication.) Dated September 1, 1858.

This relates to the manufacture of alumina from various substances, and by various processes, which, however, are grounded upon the principle involved in the artificial formation of a combination between alumina and soda, or of aluminate of soda, soluble in water mixed with an excess more or less considerable of soda or the carbonate of soda. This aluminate of soda, which results from the various reactions set up, when submitted to the action of a current of carbonic acid gas, is subject to the precipitation of the alumina, the carbonate of soda being left in solution. *Patent completed.*

1989. W. E. NEWTON. *Improvements in the construction of locks for doors, safes, and other purposes.* (A communication.) Dated Sept. 1, 1858.

This relates to that class of permutation locks in which what may be termed the key remains at all times within the lock, and the leading objects of the invention are, 1, to prevent feeling the position of the tumblers, so as to discover the combination by which it was locked; 2, to avoid the use of a keyhole, so that powder cannot be introduced within the lock for bursting it open by explosion; 3, to have the parts so arranged that force cannot be applied to the bolt to force it back until after the lock has been properly operated by the combination used in locking it; 4, to have the parts so arranged that the instrument by which the position of the tumblers is usually determined cannot be brought to act on more than one at a time, so that the proper instrument for operating the bolt cannot act upon it until the proper distribution or arrangement of the tumblers shall have been effected. *Patent completed.*

1990. W. E. NEWTON. *Improvements in springs for carriages and other purposes.* (A communication.) Dated Sept. 1, 1858.

This consists in forming a spring of a pile of steel plates or leaves, each plate of the pile being so bent as to form a series of reversed semi-ellipses. The plates are so piled one upon the other that the convex part of one plate shall be in contact with the convex part of its fellow and next adjacent plate, and *vice versâ*. *Patent completed.*

1991. S. LAING. *Improvements in the apparatus employed in the manufacture of gas.* Dated Sept. 1, 1858.

This consists in forming retorts of a barrel shape, the interior having several ribs around its circumference, the said ribs running through the barrel longitudinally, and set at an angle from each end, by which the materials are caused in their rotation to move or collect towards the centre part of the barrels, whilst the tar is collected from the ends at the centre, and being carried over is caused to fall on the hottest part of the retort. The front end or mouth of the retort is formed with a flange to receive a cover for charging or discharging the retort, and behind the flange, the retort is formed for revolving upon friction-bearing wheels or rollers, and a cast iron throat plate is formed so as to surround the throat of the retort, and prevent the escape of the flame and smoke from the oven furnace, and exclude the in-draught of cold air. *Patent abandoned.*

1992. J. WALKER and J. BARNES. *Improvements in blankets and lappings for machine and block printing and other similar purposes.* Dated Sept. 2, 1858.

The inventors employ a blanket or lapping, having cotton pile pressing surface. These blankets may be constructed by cementing together by india-rubber solution, two or more thicknesses of cotton fabric, the outer or pressing surface of such combined fabric having a pile raised thereon. *Patent completed.*

1993. G. PRICE and W. DAWES. *Improvements in steam engines, steam boilers, and apparatus connected therewith.* Dated Sept. 2, 1858.

This consists, 1, of a boiler for generating steam and consuming the smoke; 2, of a safety apparatus for steam boilers; 3, of a governor or regulator for steam engines; 4, in arrangements of gearing for closing the steam valves of engines working expansively; 5, of a lever for opening the plate or lifting valves of large steam engines. *Patent completed.*

1994. J. BLEAKLEY. *Improvements in apparatus for communicating between the guard and engine driver of railway trains.* Dated Sept. 2, 1858.

This consists in forming communications between the guard and engine driver by electricity or magnetism. *Patent completed.*

1995. J. T. PITMAN. *An improvement or improvements in the construction of pneumatic condensing apparatus for the purpose of compressing air, aeriform or gaseous bodies preparatory to their use as prime motors, or for other purposes.* (A communication.) Dated Sep. 2, 1858.

This invention is not described apart from the drawings. *Patent completed.*

1996. B. WINSTONE. *An improvement in the composition of copying and writing inks.* Dated Sep. 2, 1858.

This consists in the introduction of glycerine as an ingredient, in addition to those usually employed in making ordinary copying and writing ink. *Patent abandoned.*

1997. J. M. BULLANGER. *Caoutchouc socks or clogs with springs and without bridles.* Dated Sep. 3, 1858.

This consists in the use of metallic springs placed between the soles of the goloshes. *Patent completed.*

1998. J. ROBERTSON. *Improvements in driving belts and springs.* Dated Sep. 3. 1858.

This relates to the application of corrugated, undulated,

Digitized by Google

or indented plate or sheet metal to the construction of driving belts and springs, and has for its object the obtainment of economy, efficiency, &c. *Patent completed.*

1939. W. HARKES. *An improved plough and pulveriser.* Dated Sep. 3, 1858.

This consists in arranging a series of cutters in a circular frame directly behind the plough-share, and at right angles to it, so that as the soil leaves the plough-share it is delivered on to cutters, which are caused to revolve rapidly by gearing in connection with the wheels of the plough, so that as the plough progresses the knives rotate, and cut or pulverise the earth. The apparatus may also be employed for digging up potatoes, &c., a series of forks being substituted for the knives. *Patent completed.*

2000. E. COCKER. *An improvement or improvements in machinery for spinning, twisting, or doubling cotton, flax, silk, wool, or other fibrous materials.* Dated Sep. 3, 1858.

Here the inventor uses two or more rows of spindles, and to make this disposition of the spindles effectual, he combines it with certain variations in the construction of the spindle boxes, the fallers, the faller wires, the under fallers, and in the mode of banding or conveying the motion to the spindles, a part of these improvements being also applicable to machines with a single row of spindles. *Patent completed.*

2001. G. T. BOUSFIELD. *Improvements in knitting machinery.* (A communication.) Dated September 3, 1858.

This refers to that class of machines by which yarn is knit into fabrics, and the main object is to cause the various devices in the machine which operate directly upon the yarn to narrow and widen the fabric automatically according to a previously-conceived design or pattern. *Patent completed.*

2002. R. A. BROOMAN. *An improved apparatus for supporting the skirts of ladies' dresses.* (A communication.) Dated September 3, 1858.

This consists in fitting around the body a band of varying breadth, being narrowest at the sides. The upper line of this band is straight. The back and front are strengthened with whalebone, and the front is secured by lacings. To the upper edge is attached a frame of springs, similar to the upper part of a hooped skirt; the front ends of its hoops are secured to the sides of the broad part of the band. The framework is circular in form, although the opening when it closes around the waist is not central, but is nearly tangential to the front edge of the general circle. When the apparatus is worn it will afford a support for any number of skirts without involving the necessity of bringing any of them into contact with the waist. *Patent completed.*

2003. A. GUYE. *Improvements in the escapement of chronometers and watches.* Dated September 4, 1858.

Here the detent has ruby-locking pallets formed with angular-shaped sides, so as to form a step movement for releasing consecutively the teeth of the escapement wheel in connection with an arrangement of two hair-springs, by which the unlocking of the wheel is effected, and a dead beat of the seconds obtained. In lever watches the patentee also employs two hair-springs in connection with the ever, for steadying the action. *Patent completed.*

2004. R. P. LAVIE. *Improvements in mills.* Dated September 4, 1858.

This consists, 1, in a particular means employed for regulating and maintaining the running stone upon its pivot. 2, in the arrangement of the rhynd of the stone spindle as a breaker. 3, in the arrangement of certain parts of the rhynd and its cover, which have an upper and lower stone of small size, forming the breaker. 4, in the use of a cylinder for supplying the corn to the breaker. 5, the use of a conical helical sifter, used for separating the "middlings." 6, the use of stones, either small or large, placed one upon the other, horizontally, and directly or indirectly worked. The several parts are not described apart from the drawings. *Patent abandoned.*

2005. R. A. BROOMAN. *Improved apparatuses for receiving, containing, and delivering liquids.* (A communication.) Dated Sept. 4, 1858.

These apparatuses are intended for liquids which, on coming together, effervesce. They consist of two or more vessels combined together, or of one vessel with compartments, each vessel or compartment having an exit passage leading to one point of delivery, so that when the apparatus is inclined, the liquids from each vessel or compartment will mingle in the receiving vessel. In the interior of the vessels or compartments are placed screens, which prevent the exit of deposits, and also aid in regulating the outflow of the liquid. There is a separate opening in each vessel or compartment for the introduction of the liquids, &c., all of which can be closed by one cover or otherwise. There is also a vessel similarly constructed for containing supplies of the solutions used. The apparatuses are adapted for refreshment rooms. *Patent completed.*

2006. W. H. CHILD. *Improvements in hair and skin brushes.* Dated September 4, 1858.

This consists in constructing electrical brushes by the use of steel pins or wires in substitution for, or in combination with, bristles, which pins or wires are placed in metallic connection with a battery contained in the handle or back of the brush. *Patent completed.*

2007. W. P. PIGGOTT and S. BEARDMORE. *Improvements in vinous and fermented liquors.* Dated Sept. 4, 1858.

The patentees claim, 1, the improvement of wines, spirits, &c., by currents of electricity. 2, the use of separate porous cells containing negative and positive metals, excited in the usual manner, and connected together by wires, so as to form currents and counter-currents of electricity through the wine or spirit, &c. 3, the application of electricity to wine in bottle, by placing the negative and positive metals in connection with the cork. 4, the application of electricity to fermented liquors by making the cask, jar, bottle, &c., partly of positive and partly of negative metals or substances, so as to create currents whenever the vessel filled with liquor. *Patent completed.*

2008. D. ANDREW. *Improvements in apparatus for obtaining motive power.* Dated September 4, 1858.

This relates to the obtainment of motive power from steam, water, or air, by the agency of a cylinder and piston movement arranged to work upon the direct rotative principle. *Patent completed.*

2009. A. V. NEWTON. *An improvement in fire-arms.* (A communication.) Dated September 4, 1858.

Here a gun-stock is fitted at its forward end with a metal socket for receiving the stock of a pistol. From each side of the frame of the pistol projects a metal stud for bearing respectively against a shoulder on the edge of the metal socket. The pistol socket is held firmly in the socket by a clamp, which passes through the gun-stock, and catches into a notch formed in the rear end of the strap of the pistol. A milled nut fitted on the upper end of the clamp will cause the clamp to bind tightly against the pistol, and thus hold it firmly in place. By this addition to the pistol, the soldier may use the arm as a carbine, or the pistol may be removed and placed in the holster, the loose butt being allowed to swing from a strap with which the soldier is furnished. *Patent abandoned.*

2010. H. HYDE. *Improvements in the construction of carriage springs.* (A communication.) Dated Sep. 4, 1858.

The leaves of which this spring is composed are of an equal length, and for avoiding friction between the leaves they are separated from each other excepting at their central parts and near their ends. By this device the elastic parts of the spring are allowed to move with ease, and with little friction. The inventor secures any number of leaves in such positions that the leaves so secured can act in conjunction with the other leaves of the spring only at such times as the pressure upon the spring may render it desirable. *Patent completed.*

2011. A. HILLS. *A method or methods for the better securing the integrity or genuineness of bankers' cheques or orders for money.* Dated September 4, 1858.

The inventor makes a hole in the body of the cheque, &c., and crosses the cheque in the usual way, drawing the crossing lines above and below the said hole. In the event of crossing lines being removed from the cheque, the hole will denote that the cheque has been crossed and may only be paid through a bank. To prevent the original amount of the cheque being altered, he writes it in divided syllables, one syllable under the other transversely to the signature, so that the drawer of the cheque writes his name over and upon the words specifying the amount. There are other similar details. *Patent abandoned.*

2012. T. WARBURTON. *Improvements in machinery for preparing cotton and other fibrous materials, and for doubling yarn.* Dated September 6, 1858.

This relates to slubbing and roving frames, and to doubling frames, and consists in dispensing with the spindles used in the ordinary machines, and substituting in their stead hollow tubes, upon which the bobbins are placed. The position of the lifting rail and stationary rail is reversed, the lifting rail being underneath the stationary rail, the tube before-mentioned moving in the two rails with sufficient length above the stationary rail for the bobbin to traverse. This tube is driven by bevel-wheels. The invention also consists in lengthening the flyer-legs and attaching them to bushes which are driven by bevel-wheels in the ordinary way in the stationary rail. The flyer-legs are made of sufficient length to allow of the traverse of the bobbin. The tops of the flyers are lengthened so as to revolve in another stationary rail, which is fixed to the frame ends. By these means the flyers are held steady without the aid of the spindles, which are dispensed with, and thus a higher working speed in attainable. *Patent abandoned.*

2013. S. HOGA, W. P. PIGGOTT, and S. BEARDMORE. *Improvements in submarine electric telegraphs.* Dated September 6, 1858.

This invention was described at page 256 of our last Number. *Patent abandoned.*

2014. J. FIELDEN. *An improvement or improvements in the construction or building of cops, whether of cotton, flax, silk, wool, or other fibrous materials, and also for certain utensils thereunto conducing or belonging.* Dated Sep. 6, 1858.

Here when a fresh set of cops is to be commenced after several layers of the yarn, &c., have been wound on the bare spindles in the ordinary way, the inventor applies to the yarn on the spindles a small quantity of an adhesive substance sufficient to cement the yarn together, so as to form tubes. On these tubes the cop bobbins are built, after which the formation of the cops is continued in the usual manner. The adhesive substances used are various. *Patent completed.*

2015. J. RAMSBOTTON and T. WATSON. *Improvements in machinery or apparatus for weaving.* Dated Sep. 6, 1858.

This consists, 1, of a method of stopping a loom when an obstruction occurs in the shed by any of the warp threads breaking, to prevent the formation of "floats." The inventors fix a spring on a hollowed part of the nose or taper part of the shuttle, where it is liable to be affected by entering or leaving the shed. They attach a pin or projection to the said spring, which passes through an orifice in the nose of the shuttle, to actuate a lever in a recess, one end of which lever is caused by the depression of the spring to interfere with and break the weft thread when leaving the cop, thus causing the stoppage of the loom by any of the well-known weft motions. 2, in the use of springs or weights in connection with an L-shaped lever, the springs or weights being attached to the rising frog motion. In the use of another spring to the slay upon which the rising frog operates. In affixing the said frog in a moveable frame which recedes with the concussion, thereby giving motion to a double brake which operates upon the two opposite parts of the fly-wheel of the loom. *Patent abandoned.*

2016. R. A. BROOMAN. *Improvements in printing or marking words or figures on papers, parcels, books, pages, tickets, and other articles requiring to be marked, printed, stamped, or addressed.* (A communication.) Dated Sept. 6, 1858.

The words or figures to be printed on successive articles are arranged in type in columns, so as to run down one column and up the next. The form thus arranged is inked, and a longitudinal and lateral motion imparted to it, by machinery which causes each column to traverse at intervals, so that each name, address, figure, &c., to be marked at one time shall come successively under an aperture in the frisket. The article to be marked is placed in a fly, which nips it, and holds it over the aperture until it is pressed down by a lever, so as to receive an impression, after which the lever releases it, and the fly removes it to some receptacle. *Patent completed.*

2017. H. J. DISTIN. *Improvements in cornets and other musical wind instruments.* Dated Sep. 6, 1858.

Here the patentee so constructs cornets and other instruments of that class of brass or other suitable metal, that he has the contour or outer line thereof circular, or nearly circular, and he has the bell or pavilion and also the keys, rotary cylinders or pistons, and cylinders within or nearly within the circumference or outer line of the instruments. *Patent completed.*

2018. J. SHANKS. *Improvements in the manufacture of chlorine.* Dated Sep. 7, 1858.

This consists in the use of chromate of lime as a medium for the production of chlorine from hydrochloric acid. *Patent completed.*

2019. W. S. CHAMPNESS. *Improvements in syringes for male and female use.* Dated Sept. 7, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2020. J. FYFE. *Improvements in stop-cocks or valves.* Dated Sept. 7, 1858.

This invention relates to a valvular arrangement, consisting of a tube or through-way piece, cast or formed with an internal transverse diaphragm or division piece, so as to separate the tubular shell into two distinct portions. *Patent completed.*

2021. E. FULLWOOD. *Improvements in the manufacture of cements.* Dated Sep. 7, 1858.

This consists in mixing sulphate of iron with lime, where the lime is converted into cement preventing it from bursting after use, and rendering it hard. *Patent abandoned.*

2022. G. G. BUSSEY. *Holding and carrying cartridges.* Dated Sep. 7, 1858.

This consists of a spring clip by which the cartridge is in part encircled and grasped so as to be quite securely carried, and when required for use can be either drawn out perpendicularly, or pulled out at the side with the greatest ease and dispatch. *Patent abandoned.*

2023. W. TUCKER. *An improved variable boring bit.* Dated Sep. 7, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2024. F. W. BRIND. *Improvements in sewing machines.* (A communication.) Dated Sep. 7, 1858.

This relates to various improvements in the working parts of that class of sewing machines wherein the stitch is produced by the conjoint action of a needle and a vibrating shuttle. We cannot afford space for a detailed description of the invention. *Patent completed.*

2025. G. LARSONNIER and A. BLANCHE. *Improvements in block printing by hand on tissues, paper, or other suitable fabrics.* Dated September 7, 1858.

The object here is to offer to the printer a ready means for the application of the printing-block on the required spots of the surface of tissue paper, &c., thereby allowing of operating with great speed and accuracy. By this method each block is always obliged to apply itself exactly in the required position on the fabric. *Patent completed.*

2026. L. PELLISSIER and J. PUYTORAC. *Improvements in railway breaks.* Dated September 7, 1858.

This consists in causing suitably curved break-blocks or shoes to be pressed against the wheels. Each wheel of the carriage has two such shoes acting in opposite directions to each other in the periphery of the wheel; the corresponding shoes of each two opposite wheels are connected by a cross bar suspended from the frame of the carriage; each of the cross bars has a crank-arm, which arms are connected by rods, one rod acting with one of its ends on one of the said arms commanding the shoes of one pair of wheels, whereas the opposite end of this rod acts on one end of a balance-lever, the other end of which lever is connected by the other rod to the crank actuating the shoes of the other pair of wheels. The said rods and balance-lever receive motion by a rack, in the teeth of which acts a pinion fixed to the spindle of a wheel in gear with an endless screw, which latter may be turned in the required direction by a winch handle within reach of the guard of the carriage, thus enabling the breaks to be operated. *Patent completed.*

2027. B. HOCKIN. *Apparatus for repairing and fitting dock-gates and their machinery.* Dated September 8, 1858.

This consists in constructing in plate T and L-iron a caisson of a three-sided box-like shape, the open side being made to fit against the face of the gate, and a water-tight joint being effected by vulcanised india-rubber strips, or strips of other suitable material, close contact being secured by straps and bolts and nuts, &c. *Patent completed*

2028. J. R. ROSTRON. *An improved press for packing or pressing wool and other materials.* Dated Sep. 8, 1858.

Here the uprights supporting the top plate have at intervals two complete sets of doors, two pairs at each side of the press, one above another, which when closed form an upper and lower chamber or shaft, the lower set of doors having laths or bars which retain the over-lapping edges of the bag which is to contain the wool, &c., when the doors are closed, and hold the bag firmly in the lower chamber for the reception of the wool, &c. Upon the top plate are mounted two bevel-wheels in a moveable or sliding bearing, and supporting a spur-pinion, gearing at will either into another pinion, or into an internally-toothed disc, both of which have the screw for their centre, so that as the sliding pinion is brought into gear with the greater or lesser surface, the quicker or slower the screw becomes driven. The wool, &c., is filled into the upper chamber until the bag and chamber are full. The canvas to form the cover of the bag is secured upon the pressing plate keyed on to the screw, and the screw being put in motion compresses the wool into the bag, which is then sewn up to

Digitized by Google

the pinion; being moved to the large wheel on the disc, the screw and plate are raised rapidly, and by opening the doors the finished bale may be removed. *Patent abandoned.*

2029. J. O. BUTLER. *Improvements in weighing cranes.* (A communication.) Dated September 8, 1858.

This crane consists of a vertical pillar supported below in a footstep, and guided above in a circular rim with internal cogs, in which a pinion gears for causing the jib to swivel. To the upper part of the vertical pillar is fixed a circular platform, upon which are fixed standards, between which the frames for supporting the jib, chain, drum, and gearing are suspended. These frames have above and below bridles with pivots, which bear upon centres connected to the standards, and the whole internal framing with the jib, chain, drum, and gearing are suspended to a weigh beam or steel-yard. When this weighing apparatus is not in use, by a locking movement acted upon by a lever, the centres are relieved of their weight, and the whole internal framing rests firmly upon heel pieces cast upon the platform. *Patent abandoned.*

2030. J. F. DICKSON. *Improvements in the construction of taps, cocks, valves, hydrants, and other apparatus for regulating the flow of water and other fluids.* Dated September 8, 1858.

This consists, 1, of a tap or cock connected in the ordinary mode to the supply-pipe, wherein is fixed a clack valve with or without a hinge on its upper or under surface, opening against the pressure by a slide or plunger acting on the cam or the external face of the valve, which valve is lined with india-rubber, &c. 2, of a tap or cock having an enlarged chamber on one side to permit the working of a valve attached to an upright plug of mineralised india-rubber, such valve being lifted from its seat by a metal plug in two parts inclosed in the before-mentioned india-rubber, its action being to twist and at the same time stretch the india-rubber plug, which valve may be used either for high or low pressure purposes, as it will always be self-closing. *Patent abandoned.*

2031. A. LAMB and J. WHITE. *Improvements in life-boats.* Dated September 8, 1858.

This invention is described and illustrated at another page of this number. *Patent completed.*

2032. W. PARSONS. *Improvements in apparatus to be applied to steam-boilers in order to keep the surfaces of the tubular flues free from incrustation.* Dated Sep. 8, 1858.

Here, where a boiler has numerous parallel tubular flues, plates are employed, having as many passages through them as there are tubular flues, and the holes through the plates are made only slightly of larger diameter than the outside diameter of the tubular flues, so that by moving the plates slowly to and fro within the steam boiler all sediments or incrustation is prevented setting or forming on the surfaces of the fine. *Patent completed.*

2033. C. BARTHOLOMEW and J. BELL. *Improvements in pistons and safety-valve levers of steam and other engines.* Dated September 8, 1858.

This consists of a mode of making the piston, and of arranging the metallic packing and springs. The novelty consists in the packing pieces being in two circles in the depth, one above the other, each circle divided into three, four, or more segment pieces. The improvement of the safety-valve lever consists of applying the principle of the steelyard centre to the lever joint at the short or thick end of the lever, to avoid friction, and allow freedom of action. *Patent abandoned.*

2034. W. PARSONS. *Improvements in safety valves of steam boilers.* Dated September 8, 1858.

The valve here employed is of a spherical form on its under side, where it rests on a corresponding hollow seat. Through the valve a tube is fixed, which descends into the boiler, and at its lower end a hollow float is placed, which slides up and down a short distance upon the tube, that it may act on a rod within the tube, and by it on a whistle at the upper part or end of the tube; when the water sinks below the proper level in the boiler, provision is made for the rod moving down a certain distance by the descent of the float before it acts on the valve. The tube of the valve is weighted according to the pressure desired. Over the valve is fixed a hood, up into which the steam rises when the valve begins to open, and by acting on the interior tends to lift the valve. The hollow standard on which the seat of the safety valve is formed admits of the tube to which the valve is fixed moving or swinging therein, so that as the ebullition of the water acts on the float, and causes it to move, the safety valve is also caused constantly to move in its seat, by which it is prevented sticking. *Patent completed.*

2035. J. U. FAESSLER-PETZI. *An improved process for the boiling off of tussah silks or wild silks.* Dated September 8, 1858.

This consists, 1, in submitting the silks to three baths composed of soda, or potash, or caustic potash, or a mixture of the three dissolved in water. 2, In submitting the silks subsequently to a fourth bath composed of a solution of potash and chloride of lime. The silks must next be well washed in cold water, and then submitted to a fifth bath composed of hydrochloric or muriatic acid diluted with water. The silks may afterwards be submitted to aqua-fortis or nitric acid diluted with water. The silks must now be washed and then passed between drawing rollers. *Patent completed.*

2036. R. A. BROOMAN. *An improvement in the preparation of sulphate of quinine.* (A communication.) Dated September 8, 1858.

This consists in treating quinine by liquid hydro-carbons. *Patent abandoned.*

2037. A. MC. E. PETRES. *Improvements in apparatus for regulating the flow or passage of fluids.* Dated September 8, 1858.

This relates particularly to water-closets and urinals where a predetermined supply of water is to be periodically let in. Under one modification the apparatus as applied to water-closets, takes the form of a duplex valvular chamber or shell in three sections. The water from the main enters from beneath, and flows into the lowest section of the valvular chamber, between which section and the section above is a valve seat governed by an elastic disc or other valve, set on a vertical valve spindle, which extends upwards through the centre of the chamber, and projects out through a stuffing box at the top. This lower valve opens by a descending action of its spindle. The section above or the intermediate section of the valvular chamber, has also a valve-seat between it and the upper or top chamber. This valve opens by an ascending movement of its spindle. The central or intermediate section of the chamber has a latteral passage communicating with an air vessel, or with an elevated pipe or reservoir, whilst the upper section similarly communicates with the pan or basin of the water-closet. The duplex valve-spindle has jointed or attached to its upper end a short lever oscillating upon a stud-centre carried by a fixed arm fast to the valve-shell, whilst the other end or arm of the lever is jointed or connected to the back part of the water-closet seat. This seat is hinged upon a pair of stud centres so as to be capable of rising and falling by the action of the pressure and the removal of the pressure when in use. *Patent completed.*

2038. J. G. NEWBERRY. *An improved machine for tapping nuts, bolts, and screws, and other similar purposes.* Dated September 9, 1858.

The specification of this invention, which involves much minute detail, is too long to permit of our giving an intelligible abstract of it in our pages. *Patent completed.*

2039. J. LUIS. *An improved life-preserver raft or buoyant mattress.* (A communication.) Dated September 9, 1858.

This relates to mattresses stuffed with cork shavings, and consists in providing a ship's mattress with straps and buckles on their upper and under surfaces, and with loops round their edges in a peculiar manner. By this means a series of mattresses can be buckled together, and a life-preserving raft formed, by placing several layers or tiers of the mattresses buckled together on the top of one another in a manner to form angular break joints. *Patent abandoned.*

2040. W. PRISLEY. *Advertising by day or night.* Dated September 9, 1858.

The patentee first removes the top or upper part of any of the lamps, &c., now in use for lighting streets, &c., and affixes to the lamp, in the place of its ordinary top, an addition or elongation, which is not described apart from the drawings. *Patent completed.*

2041. J. ROWLEY. *A new compound material applicable as a substitute for leather and leather-cloth, in the manufacture of various useful and ornamental articles.* Dated September 9, 1858.

This consists in coating any felted, woven, or textile fabric, with a peculiar kind of paint, forming the subject of letters patent, No. 109, dated 20th June, 1858. *Patent completed.*

2042. W. TAYLOR and P. A. BAVON. *An improved apparatus for propelling ships or other navigable vessels through water.* Dated September 9, 1858.

This consists of an angular framework suspended on a shaft or shafts along the side or stern of the vessel. Connected to the framework are two or more boards or flaps, suspended by a hinge at the centre of the angular frame, to allow the boards or flaps to open and close by the reciprocating motion transmitted through a beam and rods, by which action the vessel is propelled, either ahead or astern. *Patent abandoned.*

2043. C. N. KOTTULA. *Improvements in the manufacture of grease for lubricating purposes.* Dated September 9, 1858.

This consists in the manufacture of grease from saponified resin and fatty or oily matter. *Patent completed.*

2044. J. TATLOW and H. HODGKINSON. *Improvements in railway breaks.* Dated Sep. 9, 1858.

Here the brake proper consists of two parts, one of which is a brake block attached to a jointed arm, and extends down nearly to the rail; and the other is a brake band that may be divided at one, two, or more places, and attached to a metallic band correspondingly jointed. The arm which carries the brake block at one end is jointed at the other end to the carriage frame, and the brake band is connected to it near the brake block. The other end of the brake band is connected to one arm of a bell-crank lever for imparting to it such a motion that when the said end is pulled upon both the brake block and the brake band may be thereby drawn tightly against the wheel. *Patent completed.*

2045. T. TIMMS. *Improvements in bits.* Dated Sep. 9, 1858.

Here a bit is made with cheeks or side bars, so that a rein may be attached near to or at the ends of the bit, and the horse is then driven as if with a snaffle; but in the event of more power being required over the horse, the act of pulling on the rein causes the ends of the rein to slide down the cheeks or slide bars further and further from the bit, and thus greater leverage is obtained; this is accomplished by having two sliding pieces on the cheeks or side bars of the bit, to which the two ends of the rein are attached. These sliding pieces are constantly acted on by springs of vulcanised india-rubber, so as to keep them near the bit; but as the rein is more and more pulled on, the side bars or cheeks assume an inclined position, and the springs yield to allow the sliding pieces to move along the bars away from the ends of the bit, and thus is the leverage increased; but so soon as the horse yields, the springs draw back the sliding pieces towards the bit. *Patent completed.*

2046. J. WRIGHT, sen., and J. jun. *Improvements in machinery and apparatus used for preparing fabrics or materials to receive eyelet holes or fastenings, and fixing eyelet holes, and in fastenings for stays and other articles.* Dated Sep. 9, 1858.

This invention cannot be satisfactorily described apart from the drawings. *Patent completed.*

2047. W. NIMMO. *Improvements in weaving checks in power looms.* Dated Sep. 9, 1858.

The peculiarity of this invention consists in arranging a power loom so that from time to time it shall cause a greater number of picks of the weft to be thrown into a given length of fabric than at other times. *Patent abandoned.*

2048. A. BAADER, jun. *Improvements in the preparation of lubricating compounds.* Dated Sep. 9, 1858.

This consists in combining quicksilver and asbestos with the following fatty and oily matters:—Tallow, rape, oil, sheep's fat, linseed oil, and hog's lard. *Patent abandoned.*

2049. W. CLARK. *Improvements in materials for dyeing and printing.* (A communication.) Dated September 9, 1858.

This applies particularly to the manufacture of the tartrates, citrates, oxalates, and chromates of baryta, and the ferro-cyanide of barium, by liberating their acid by the addition of a quantity of hydrochloric or sulphuric acids sufficient to saturate the baryta. *Patent abandoned.*

2050. J. L. CHESTER. *Improvements in self-priming apparatus for fire-arms, and in the preparation of percussion primers to be used therewith.* (Partly a communication.) Dated September 10, 1858.

These primers are composed of the usual ingredients, but made into thin flat discs, and arranged one upon another in a tube, or other similar device, and are then or subsequently moistened with gum, shellac, caoutchouc, or other adhesive matter having waterproof qualities, so that they will adhere together in the form of rolls when removed from the tube, and the rolls be coated with a coating thereof. *Patent completed.*

2051. J. PARKER. *Improvements in steam boilers.* Dated September 10, 1858.

This consists in the use of a supplementary boiler supported within the flue or flues of a Cornish or other boiler having suitable flues, and connected to the main boiler through one or more passages. The feed water may pass through this supplementary boiler, or the supplementary boiler may form part of the main boiler, and it may be made with an internal flue. *Patent abandoned.*

2052. J. KNOWLES. *Certain improvements in machinery for preparing cotton and other fibrous materials.* Dated September 10, 1858.

This consists of a stopping motion applicable to all the machines used in preparing cotton and other fibrous materials, and that are fed or supplied with slivers or rovings by means whereof such machines may be instantly stopped, when one of the slivers or rovings breaks or otherwise ceases to be supplied. The patentee claims the application of differential wheels to the stop motions of machines used in preparing cotton and other fibrous materials. *Patent completed.*

2053. J. P. KŒNIG. *Improvements in a surgical instrument called a pneumatic catheter.* Dated September 10, 1858.

This instrument is designed to supersede fropes, bougies, &c., employed in the treatment of the genito-urinary parts, fistula, lachrymalis, and also external and internal affections of the ear. The instrument is not described apart from the drawings. *Patent completed.*

2054. J. H. JOHNSON. *Improvements in Jacquard machines.* (A communication.) Dated September 10 1858.

This relates, 1, to a peculiar construction and arrangement of the card-actuating cylinders employed in Jacquard machines. 2. To a mode of changing the position of the cards on the cylinder. 3. To a mode of allowing for the longitudinal expansion of the cards. 4. To a system of adjusting the ends of the needles to the expansion or contraction of the cards. *Patent abandoned.*

2055. F. W. J. JOHNSON. *Improved means of communicating between the passengers, guard, and engine-driver of railway trains.* Dated September 10, 1858.

This consists in providing tubes of india-rubber &c., for communicating with the guard. *Patentabandoned.*

2056. F. A. E. GUIRONNET DE MASSAS. *An improved machine for decorticating and cleaning grain and seeds.* Dated September 10, 1858.

Here a drum of wood is fixed on an axis free to revolve and inclined to a certain extent, the drum is covered with punched iron similar to that used in cleaning operations in mills, and the drum extends over a portion of the length of the axis, and immediately beyond it on the same axis is fitted an arrangement of brushes forming a screw. On the punched iron-covered drum are fixed blades or arms, so arranged as to form an interrupted screw for conducting the grain. These arrangements are enclosed in a fixed casing formed of punched iron at the upper part opposite the drum, and of wire-cloth at the lower part, or opposite the brushes. The punched-iron part of this casing may be enclosed in an outer casing. On rotary motion being communicated to the apparatus, the grain fed-in is conducted from the upper to the lower end, by the inclination of the axis, the interrupted screw on the drum, and the screw-form of the brushes, all choking or reciprocal pressing of the grains among themselves being thereby prevented, while the action of the punch-iron and brushes effects the decortication and cleaning; the punched iron tearing the outer, skin the interrupted screw guiding the grain or seeds to the brushes, and the brushes conducting them to the outlet decortication and cleaning being thus performed on them during the whole of their progress along the apparatus. *Patent completed.*

2057. W. E. NEWTON. *An improvement in water-wheels.* (A communication.) Dated September 10, 1858.

This relates to an improvement in that class of water-wheels in which the water is made to act upon the wheels by atmospheric pressure or suction, produced by a vacuum formed in a draught tube below the wheel. The invention consists in a peculiar construction of the wheel and gates in connection with the draught tube, which construction is not described apart from the drawings. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, APRIL 29, 1859.

THE ADMIRALTY COMMITTEES.

The Admiralty Committees appointed to investigate the various branches of our naval affairs during the last year and the present are among the most interesting curiosities of the period. Ostensibly appointed in the interest of the public, and really eliciting from necessity much useful information, their composition has, notwithstanding, been of so singularly absurd a character that their recommendations are for the most part worthless to the country. That they will to a certain extent serve, and have already served, some of the purposes of the ingenious politicians and scheming administrators who appointed them cannot be doubted; but that they will do much more than this no well-informed person can believe.

The first of these precious committees consisted, it will be remembered, of a late Secretary to the Treasury, the present Secretary to the Admiralty, the Accountant-General of the Navy, and a Treasury Clerk, and as an example of the modesty with which these gentlemen performed their duties, it is only necessary to say that their chief practical recommendation was that our dockyards should for the next year be exclusively employed upon the conversion of sailing ships into steamers. Now what in the name of reason do these clerks and secretaries know of matters of this kind? Are they aware that when a sailing ship is converted into a steamer the vessel thus produced, although cheap for the moment, is liable to early decay from the old timber left in her; is of an intrinsically bad form for all the purposes of a steamship; and cannot be made either so capacious, so fast, so handy, or in any single respect so useful as a vessel designed expressly as a steamship? Do they know that by confining our efforts to the conversion of sailing ships only we should be absolutely depriving ourselves of every chance of competing with the new ships building by France, America, and other powers? Have they any adequate means whatever of forming a sound opinion upon so purely professional a subject as this? Certainly not.

The next Committee appointed consisted of Admiral Ramsay, Mr. James Nasmyth, and Mr. Ward, and their business has been to examine the steam machinery of the navy. What are their qualifications for the task? Admiral Ramsay, being an admiral, cannot be expected to speak with much authority upon such a subject; Mr. Nasmyth is almost the only eminent English engineer whose professional depth and soundness are called in question, because he is the only one who puts forward impracticable schemes, and the only one who devotes much of his time to the study of the moon; and Mr. Ward, of Keyham, is remembered in the navy only as the producer of certain strange, not to say alarming, specimens of boiler incrustation! We are not surprised therefore to find that their report is a very curious one, as it most certainly is. We are not astonished to see such a committee as this at point blank issue with the only thoroughly qualified member of the Administration at Whitehall — the Surveyor of the Navy. We do not wonder at finding such a committee accused by that officer of making foolish imputations "without a shadow of evidence," to use his own language —of omitting altogether to apply to the Surveyor himself for information — of selecting witnesses who could speak with no kind of authority, and neglecting others whose evidence would have been valuable—and of other like things, which we shall mention on a future occasion.

The third Admiralty Committee, which has yet to report, consists of Admiral Smart, Mr. Laws, the Storekeeper of Chatham Dockyard, Mr. Chatfield, the Master Shipwright of Deptford Dockyard, Mr. Murray, the Chief Engineer of Portsmouth Dockyard, and one of Mr. Lindsay's foremen, we believe. Dockyard economy is the subject into which these gentlemen have to inquire, and upon which they have to write. Now we have but little to say against these gentlemen individually, except to state that one or two of them is believed to be devoted too ardently to personal crotchets. But who can for a moment believe that such a committee are competent to pronounce any conclusive judgment upon affairs involving an expenditure of many millions annually? That they would be so, even if unanimous, we strongly deny, for their number is far too small. But, judging from our knowledge of most of these gentlemen themselves, and from rumours that have been floating for many weeks past through the dockyards, we believe they are by no means of one mind.

It is of the first importance, therefore, that the action which the Admiralty may venture to take upon the recommendations of these committees be closely and intelligently scanned. The constitution of the committees shows clearly enough that their design is not improvement but interference. If we had forgotten the Derby Admiralty of 1852, late events would have guarded us against the manœuvres, not to say the machinations, of the party who now rule at Whitehall, and would have given us ground for keeping anxious eyes upon their proceedings. But we have not forgotten the past, nor do we fail to recognise the animosities of a former period working secretly but surely in the present. It is becoming daily more and more evident that mischief is meant by the present heads of the Admiralty and their colleagues; but our hope is that their devices will be frustrated, and that the officers to whose hands the efficient extension of the navy are intrusted will be speedily freed from the embarrassments with which the last year has been so rife. If they be not, the country will rue—perhaps bitterly—the day when its affairs were committed to the management of the present Government. This is no time for trifling with our naval establishments merely to gratify political or personal jealousies and hatreds; and if Sir John Pakington and his colleagues cannot be patriotic enough to sink all considerations of partizanship under existing circumstances, we must do our best to keep the public sense alive to the evils with which we are threatened.

THE PRACTICABILITY OF INTRODUCING A DECIMAL COINAGE IN ENGLAND.

We have taken some pains to ascertain the number of silver and copper coins of the various denominations in circulation throughout Great Britain at present, with a view to demonstrate the mechanical possibility of substituting for them a new coinage of silver and bronze on a decimal plan. The social difficulties to be encountered in effecting so great and salutary a change we leave to the Decimal Coinage Commission, and to Lord Overstone, who does not seem disposed to make the least of them. The annual returns of the coinage laid before Parliament, prove that there are, or ought to be, in existence, as regards silver coins, of—

Crowns	2,250,000
Half-Crowns	37,500,000
Florins	10,000,000
Shillings	113,000,000
Sixpences	80,000,000
Fourpences	20,000,000
Threepences	8,000,000
Total	270,750,000

and as regards the inferior copper coins, of—

Twopenny pieces (obsolete) ...	722,200
Pence	115,000,000
Halfpence	270,000,000
Farthings	100,000,000
Half-Farthings	70,000
Total	485,792,200

The aggregate number of silver and copper coins therefore which, setting aside hoardings, losses, &c., may be considered to be now in circulation, amounts in round numbers to 756,542,200—a goodly number truly, and one which, if divided equally among the thirty millions of inhabitants of the British islands, would fill the pockets—for a little while—of everybody. The Mint is capable of producing, and has been producing lately, if report speaks truly, a million of pieces per week; and doubtless it might easily be made yet more productive by the addition of further mechanical appliances. Well, fifty-two millions of old coins annually withdrawn from circulation, and replaced by fifty-two millions of new, would extend the operation of exchanging the coinage completely over about fifteen years. It has taken fifty years, however, to raise the number of coins to those shown in our table, and this would demonstrate an improvement in the present system of coining over the past nearly in the ratio of three to one—as regards rate of productiveness.

But the Mint might, if more speed still were necessary, be supplemented in its exertions by contractors, who would pour large streams of bronze coin into the great channel of circulation, whilst the Royal establishment might replenish it with gold and silver only. There is indeed no question but that the existing coinage—worn, torn, and heterogeneous—might, within the space of half-a-dozen years, be entirely supplanted by a handsome and uniform coinage on the decimal plan, which would be at once a credit to the scientific, the artistic, and the mechanical character of England, and a convenience to the tradesman and merchant. When the election and its turmoil is over perhaps Parliament may look to this important subject.

EXPLOSIONS AT GUNPOWDER WORKS.

This subject is one which, setting aside the vital considerations it involves, reflects the greatest disgrace upon our boasted progress in chemical science. What is there, it is emphatically asked, in the whole range of discovery besides the gunpowder manufacture that has stood still throughout the world, and has not been improved by the deep-searching minds of modern men? Manufacturers appear to consider that unsusceptible of improvement; but the men of the laboratory are at direct issue with them, or why is it that a week scarcely elapses without some "pestering suggestion" of the practical chemist disturbing those made rich by its production? The gunpowder manufacture—one of the closest and most profitable of monopolies—supported and highly paid by the Ordnance, affects the airs and exclusiveness of its chiefs, and superciliously rejects every

Digitized by Google

suggestion which would involve the smallest disturbance of its antiquated routine. We have it on record that the Ordnance Committee of 1855 condemned every invention submitted to it. "One thousand and five persons, amongst "whom were some of the most scientific men in "England, made suggestions, upwards of 6,000 "in all. All were rejected." The gunpowder manufacturers out-Ordnance the Ordnance. They not only week by week, but year by year, perseveringly and systematically thrust aside all proffered aid. Frequent explosions have closed their ears to every appeal that has for its object the discontinuance of these fearful calamities. In such a case what is to be done? Are the lives of men, the weal of families, and the prosperity of large districts to be left to the mercy of those who are *in* the present century but not *of* it? Can Government do nothing for us? Would a few hundreds spent upon a commission to inquire into these calamities, and to hear the suggestions of those who have devoted days and nights to the practical solution of their causes, bring any relief? If so, the sooner the better; for Hounslow Heath, once the rendevouz of Turpin, of Abbershaw, and their "pals," is now a populous neighbourhood; the gorse has been succeeded by the garden, and houses are closing in the precincts, and will ere long peep over the palings of the grounds devoted to gunpowder and to death.

The causes assigned for the non-removal of gunpowder works to such safe, because desolate, places as Salisbury Plain, or to floating and disconnected factories in the centre of large lakes, are thought by some to have reason in them —"Distance of transport increases the danger "of explosions," for example. But if this be true, how is it that we never hear of explosions of large quantities of gunpowder after it has quitted the works? At Bugsby's-hole on the Thames, the place named by Government for the shipment of gunpowder, nothing more than the most trifling accidents have happened, and we cannot call to mind any occasion in which an accident has happened between that spot and the several mills throughout the kingdom, or, after this land carriage, on the many thousands of miles which the powder has often had to travel by water. We are, of course, willing to admit that a greater cost would be incurred by the manufacturer in the carriage of the ingredients to the mills, as well as in the transport of the powder itself from them. But is not this, after all, exclusively a money consideration, in no wise affecting the social and vital question of life and property? Such objections are no more tenable than a second one, which is brought against an advance of wages to the men employed in the most hazardous portion of the factory. "It has been found by "experience that the low rate of wages keeps "men sober, and that every extra penny be-"yond the scale would be an additional induce-"ment to drink." Here, at least, is consistency! The specious reasons made use of against improvements in the manufacture of gunpowder are here brought against any advance in the payments to the men. The question, then, appears to be, not that more is not due to them, but that they cannot be entrusted with it. If any such conviction really exist in the minds of the masters, we would earnestly suggest that they visit the homes of their men, and at their neat, cleanly, and well-ordered hearths they will find the most substantial evidence that any rational increase of wages would be no super-inducing motive to other than habits of frugality and industry.

In Austria the most dangerous stages of gunpowder manufacture are wholly conducted in pits and excavations beneath the surface of the earth. The consequence of a "blow" under such circumstances is to expend the whole lateral force of the powder upon the sides of the trench, and these being elastic in their nature, act as a buffer to deaden shocks seldom felt beyond a comparatively few yards from the place of the explosion. The upward tendency of the blow is of course directed against the heavens only. It is evident that this practice receives the sanction of the British manufacturer, for he essays to imitate the Austrians, but proves in so doing that there are two ways of attempting the same thing—a right and a wrong. While admitting the principle, our manufacturers erect their mills upon the *surface* of the soil, and surround them and their dangerous charges with a raised mound of earthwork. When a "blow" takes place, this encrusted barrier is scattered in pieces to the four quarters of the winds, and deals destruction to life and limb to all within its range. At the recent accident, not a vestige of this mound was left standing, and the oft-repeated assertion of the advocates of its utility, who state that such opposing walls must be necessarily blown to harmless dust, must have received the most convincing evidence of their error in the huge pieces of the wall which were scattered to some fifty yards or more from their positions. We fear that if a "return of the ac-"cidents resulting from the manufacture of "gunpowder" were to be moved for and honestly rendered, it would afford a fearful account of killed and wounded. Indeed, those living around Hounslow itself, who are now, after the loss of a limb, or distortion in face or form by hideous scars, following some less dangerous calling, would form a most formidable corps of disabled followers for a *peaceful* occupation. The suggestion that convicts should be alone engaged in the more hazardous employment of gunpowder works is, we are informed, at length engaging the attention of the Government, with whom it is to be hoped the truly absurd objections to the employment of this class of operatives will have but little, if any weight.

A notice of a few of the many causes of the explosion of gunpowder mills may be interesting to our readers. At Dartford, a cricket ball struck by the batsman across the stream fell upon the gravel path and bounded from thence into the trough of the grinding wheel. The ball getting beneath the wheel caused it what is technically called to "kedge" or drag. Friction was occasioned thereby, and an explosion was the consequence. The boy who ran round to get the ball saw the state of things, plunged head foremost beneath the stream, and arose uninjured amidst a shower of falling *debris*. In loading a waggon from a punt a barrel of powder fell, and exploding, caused the destruction of several lives. A man half immersed in water, while cutting the sedges at the side of the river which feeds the mills, struck his sickle against a stone and occasioned a spark. He saw with fear little trains of smoke arise over the powder-bestrewed path, but had the presence of mind to scoop up water with his hands and throw over and put out the dangerous ignition. At one mill, eleven men and seven horses were blown to fragments. A boy whose duty it was to stand at the horses' heads of one of the waggons complained of cold, and got another lad who was passing to take his place while he went into the corning house to warm himself. While thus employed the accident occurred, but the remarkable portion of our "note" upon this instance is:— "The boy regrets that he neglected his duty, as "his pay has been stopped in consequence." It has been before remarked that great atmospheric changes have often preceded the explosion of gunpowder works, and the last at Hounslow was not an exception to this fact. But of this phase of the question, more anon.

THE SOCIETY OF ARTS' EXHIBITION OF INVENTIONS.

THE Eleventh Annual Exhibition of Inventions was opened at this Society on the 25th inst. It is a very interesting exhibition, but as the catalogue—which is profusely illustrated—may be obtained for 3d. or 4d. at any part of the country, we think it scarcely worth our while to do more than announce the opening of the exhibition, and recommend our readers either to visit it in person, or, where they cannot do that, to procure the catalogue.

Literature.

The Life of James Watt, with Selections from his Correspondence. By JAMES PATRICK MUIRHEAD, M.A., &c., with Portraits and Woodcuts. Second Edition. London: John Murray, Albemarle-street. 1859.

SOME reviewers of valuable works like this, instead of sending their readers to the volume, by pronouncing deserved eulogies upon it—which they should do, in justice to both authors and publishers—adopt the selfish practice of cunningly extracting all or most of the author's new and striking facts, and building from these a highly entertaining article—*of their own!* This practice is not, in our judgment, an honest one, and we will not follow it. The life of Watt needs study—for our own sakes. What man is there among us who will fail, now that the means are before him, to trace back the history of that giant, the steam-engine, to his beginnings in the breast and brain of its author—we may fairly dignify Watt with that name.

We have here the latest, the richest, the completest, the best life of Watt. We cannot give a better statement of the nature of the work than the author furnishes in his preface. This, therefore, we quote below, with the earnest hope that it will attract many readers to the volume itself. It is as follows:—

"The present volume may, it is hoped, supply a want which has long been felt; that, viz., of a full, yet compendious and authentic biography of James Watt. In a recent work,* prepared by the authors from the MSS. of the great engineer, preserved by his son, as well as from others of no less value, in the possession of Mr. Boulton, there were comprised. (1.) a biographical memoir of Mr. Watt; (2.) a selection from his correspondence; and (3.) the specifications of all of his patents. The favour with which that work was received by the press and the public is gratefully acknowledged. The long series, however, of large copper-plate engravings of machinery by which it was illustrated—(thirty-four in number, delineating no fewer than sixty-eight separate figures)—necessarily raised its cost above the means of many who might otherwise have desired to possess it; while the minute descriptions contained in the specifications of patents, and their relative drawings, are of course more desirable for the use of the scientific engineer and the mechanical philosopher, than of the general reader.

"The author has now, therefore, ventured to remodel and to reproduce in a form at once more comprehensive, more convenient, and less costly, the biographical memoir above referred to. A few unimportant pages have been omitted; many of the most interesting passages from the correspondence of the great engineer have been incorporated; and other large additions, from various sources, have been made,—a considerable portion of the new matter relating to Mr. Watt's family and private history; while the principle has been adhered to of allowing his inventions and discoveries to be explained, as far as possible, in his own plain, clear, and forcible language.

"Of the immense results of those inventions, and

* "The Origin and Progress of the Mechanical Inventions of James Watt." 3 vols., 8vo and 4to. London: John Murray, 1854. This work was reviewed in the MECHANICS' MAGAZINE, Vol. 62, Nos. 1647-8, pp. 193-225.

Digitized by Google

their present and future value to the world, it is already difficult to form any adequate conception. But some faint idea of their magnitude may be gathered from such facts as these:—that less than a single century ago, only a few clumsy and imperfect 'fire-engines,' of the old atmospheric sort, were employed in pumping water out of some widely-scattered coal-pits and mines—that they did their task laboriously, expensively, and badly—that steam was not then applied directly, nor, as then used, was it capable of being applied, with advantage, either to manufactures, to processes in the useful arts, to navigation, to land transport, to war, or to agriculture, and that now, the united steam-power of Great Britain alone, employed in all of those different ways (every engine having been constructed since the improvements of Watt were first made known), is estimated as equivalent to the manual labour of upwards of four hundred millions of men, or more than double the number of males supposed to inhabit the globe. How startling are such statistics—how eloquently is the panegyric of the inventor thus expressed by the stupendous works of his genius!

"As a kinsman of the illustrious engineer—as long the intimate friend, and now one of the executors of his son, and as the son-in-law of the late Mr. Boulton, the author has enjoyed the peculiar privilege of unrestrained access to the stores of original documents, as well as of anecdotes, by which this volume has been enriched. This circumstance may be a sufficient guarantee of the genuineness and interesting nature of the materials from which he has had to select; and the care bestowed in moulding them to their present form will be well repaid if it secures a complete and accurate history of the life of one whom the common consent of mankind has now placed 'at the head of all inventors, in all ages and nations.'

"The checkered career of so great a man—now dark with shadows, now bright with lights—may well teach the stern truth,—

'That life is not as idle ore,
But iron dug from central gloom,
And heated hot with burning fears,
And dipp'd in baths of hissing tears,
And battered with the shocks of doom
To shape and use.'

Yet it is full of hope and encouragement to those who read its lessons aright. For it sets forth the dignity of that intellectual pre-eminence which crowns perseverance in honourable toil—the lustre of that nobility of soul which finds its highest scope even amid humble pursuits—the majesty of that wisdom which intently, tranquilly, and reverently searches out the mysterious works and ways of Creation.

'Fame is no plant that grows on mortal soil,
Nor in the glistering foil
Set off to the world, nor in broad rumour lies;
But lives and spreads aloft by those pure eyes
And perfect witness of all-judging Jove;
As he pronounces lastly on each deed,
Of so much fame in heaven expect thy meed.'"

New Resources of Warfare, with Especial Reference to Rifle Ordnance, in the Chief known Varieties, including Authenticated Weight, Measurement, and Mode of Construction of Armstrong's Wrought Iron Breech-loading Guns; together with an Account of their Shells and Fuses. Illustrated by Descriptive Drawings. Being a Supplement to "Projectile Weapons of War and Explosive Compounds." By J. Scoffern. London: Longman, Brown, and Co. 1859.

The name of Mr. Scoffern is known to us, but we readily acknowledge that this is the first of his books which has come under our attentive notice. It professes to afford much new and "authentic" information respecting the Armstrong gun, and its profession in this matter is carried out in a most remarkable manner.

Let us first describe the general features of the book. It is very small—considering its pretentious title—and, although its pages number seventy, it would altogether make but little more than six of our pages if printed in type like that in which "Our Weekly Gossip" is set on another page. It is, however, beautifully printed on excellent paper, and neatly bound in red cloth.

Now for its contents. It contains three chapters: the first (of seven pages) on the balance of destructive forces; the second, on Paixhan shells and rifled small arms; the third, on forms of rifled ordnance, war rockets, floating batteries, and shells. The reader will, if he please, take our word for the fact that he must know extremely little about ordnance and projectiles in order to learn much of a scientific nature from the book. We can only consider all that does not relate to the Armstrong gun as little better than so much verbiage scrawled down for the mere purpose of making a book. This is not an illiberal interpretation; but a conclusion forced upon us by the discursive, inconclusive, and aimless character of what we find in the volume.

Let us turn our attention, therefore, to that portion of it which relates to the Armstrong gun. On the first page we find the following words in italics:—"*I am able to supply, for the first time, a full explanation, accompanied by correct drawings, of that gun;*" and to this remark is appended this foot-note:—

"I am aware that a technical illustrated journal has published drawings of the Armstrong gun. The editor very fairly stated that he could not vouch for their perfect accuracy; and, indeed, they will be found to differ from my drawings of the gun (obtained from a reliable source, and which I can depend upon) in some important particulars. To cite an example:—the breech screw of the Armstrong gun is perforated as described at p. 37, whereas the journal referred to depicted it solid. Other particulars of discrepancy will be discovered by reference."

Now, it will be in the recollection of our readers that when we gave drawings illustrative of the principle of the Armstrong gun, we distinctly stated that they were to be considered only as "rough representations" of the principal features of the weapon. In the following number we also corrected the only error which occurred in our long description of the gun, by saying "the large screw at the breech is formed hollow." This correction was published nearly seven weeks ago, but Mr. J. Scoffern has found it convenient not only to ignore it but to make a pompous allusion to our error in the note above quoted. On p. 37 he repeats the allusion in another foot-note. We will not say why this correction of ours is ignored: all we will do is to state that if Mr. Scoffern had acknowledged that correction he would have left himself without the smallest shadow of justification either for writing the above foot-note, or for describing the Armstrong gun at all. The only drawing of the gun which he shows, and of the pretended accuracy of which he makes a great parade, is less like the gun itself than our sketch, rough as it was, and little importance as we attached to it. On the very point in question—the passage from the screw—although Mr. Scoffern's drawing shows such a passage, he gives the reader no information whatever respecting the object of it! On the other hand, he shows no enlargement whatever in the bore at the breech end; and yet that is a most essential feature of the gun. Certain unessential features of the gun, in which we made no attempt at accuracy, are either copied from us into Mr. Scoffern's drawing, or stumbled upon by him accidentally; but, however he got them, they are not, as he pretends, "correct." All that he says in his title-page about the weight, "authenticated measurement, and mode of construction" of the Armstrong guns means no more than that in the book he repeats much of what we published weeks ago (leaving out, however, much that is most important) and adds this foot-note:—

"Armstrong's cannon have hitherto been constructed of two dimensions only, the larger having a bore of 3¼ inches, the smaller a bore of only 2½. In either case the pitch of rifling is one revolution in 12 feet. The weight of the larger gun is 18 cwt., of the shell, 32lbs.: the lighter shell weighs 18lbs."

We shall spend no more time and space on this volume. However any man with common sense can have written and put his name upon such a production, after the universal circulation of our article, we cannot conceive. Every reader of this Magazine has as great a right as Mr. Scoffern to take our article on the Armstrong gun, add one or two facts, omit several, misunderstand more, make a blundering copy of our engravings, and then publish a volume on one of the great topics of the day. We do not say he has done this; but we do say he might have done it, and then have sent forth just such a work as that before us.

Recent Practice in the Locomotive Engine. By D. K. Clark, C.E., and Z. Colburn, C.E. Parts 3 and 4. Blackie and Son, London, Edinburgh, Glasgow, and New York.

It is only necessary here to mention the contents of these parts of this very useful work. The steel engravings are, as usual, of the highest excellence, and the letter-press is profusely illustrated with carefully-executed wood-cuts. Part 3 treats carefully of the combustion of both coke and coal, chemically and practically, and furnishes an inquiry into the qualifications of the ordinary locomotive boiler for the combustion of fuel. Part 4 gives a succinct but lucid, and, on the whole, fair notice of the various expedients adopted for burning coal in locomotives, with some account of the results obtained with it in practice. Mr. Clark's own system of inducing air currents into the fire chamber by means of steam jets is noticed with the approbation it deserves, and with no more. On what ground, however, does the author state that the brickwork used by Mr. Lees in his apparatus is troublesome to maintain? We have close knowledge of the operation of Mr. Lees' apparatus, but have not remarked this defect.

Abridgments of the Specifications of Patents for Inventions relating to the Manufacture of Paper, Papier Mâché, &c. Printed by order of the Commissioners of Patents. Published at the Great Seal Patent Office, 25 Southampton Buildings, Holborn. 1859.

Those who are wise enough to put themselves in possession of the cheap but invaluable series of abridgments of which this forms the last published volume, will only need to see it announced. To others we may say that if it will be either interesting or profitable for them to possess a brief description of every invention patented in Great Britain for the manufacture of paper, pasteboard, and papier mâché—patented, that is, between 1665 (when the first patent was granted) and December, 1857, they can do so by obtaining this little blue book.

On the Relative Power of Metals and Alloys to Conduct Heat. Part I. By F. Crace Calvert, F.C.S., &c., and R. Johnson, F.C.S., &c. From the Philosophical Transactions. Part II. for 1858. London: Taylor and Francis, Red Lion Court, Fleet-street. 1858.

The experiments here recorded have already taken their place in the treasury of scientific knowledge. Readers will be glad to observe that the paper is procurable in a separate form.

Fire Bricks.—That very important element connected with the fittings of all local steam apparatus, a thorough fire-resisting brick, is now being made at Grays, Kent, clay having been there discovered which, it is said, is equal to the well-known Stourbridge. Specimens have been shown to us at Messrs Robinson, Nicholls and Co., the British Mercantile Agency, 13 Old Jewry Chambers, City.

INCENDIARY SHELLS FOR WARFARE.

(From the *Morning Advertiser.*)

CAPTAIN NORTON presents his compliments to the Editor of the *Morning Advertiser*, and begs that he will be so kind as to give insertion to the enclosed letter, as the intemperate and groundless accusation contained in the letter signed "Justice," in the *Sun*, of Captain Norton having infringed upon Mr. Macintosh's Patent in his experiments at Chatham, cannot be too speedily and publicly refuted.

Rosherville, 23rd April, 1859.

TO THE EDITOR OF THE "MORNING ADVERTISER."

SIR,—Under the above heading in the MECHANICS' MAGAZINE of yesterday, I have read a letter signed "Justice," and dated the 17th inst., addressed to the editor of the *Sun*. I did not see the *Sun* of that day, or I would have instantly answered it, by quoting an extract of a letter to the editor of the MECHANICS' MAGAZINE, dated 20th December, 1855, and inserted in their number, 12th January, 1856, on the subject of Captain Disney's liquid fire shells. Extract.—"I do not pretend to any claim on the liquid fire concoction —bisulphuret of carbon and phosphorus—which I consider to be the most 'naufragious' fire stuff ever invented by the ingenuity of man." In my late experiments at Brompton, Chatham, I only used my *own* rifle-shells charged with the liquid fire, without adding asphalt or any other matter. The liquid was the same that Dr. Scoffern gave me about three years ago, and Mr. Wentworth Scott filled a few of my shells with his *own* liquid fire, which I fired in his presence in the garden of the Rosherville Hotel, about the same period, and found his liquid to be very potent, as reported in the daily and weekly papers of the time. I am, Sir, your obedient servant,

J. NORTON.

Rosherville, 23rd April, 1859.

THE ESTIMATES OF THE ENGLISH AND FRENCH NAVIES.

(Concluded from p. 265.)

It will be seen that France, since 1852, has increased her steam line-of-battle ships from 2 to 40, of which there are 5 building and 4 converting, and that this has been effected by the conversion of 26 sailing-ships, and the building of 14 screw-ships. England, in the same time has increased her line-of-battle screw-steamers from 17 to 50; of which there are 10 building and 7 converting. This has been effected by the conversion of 27 sailing-ships, and the building of 23 as screw-ships. The addition, therefore, to the French navy, in steam-line-of-battle ships, complete, building, and converting, is 38, and of England, 33, since 1852. France has, at present, 4 iron-sided ships (*"frégates blindées"*) in course of construction, as before stated. The steam frigates of France, screw and paddle, have been increased from 21 to 46; and England has increased her steam-frigates, screw and paddle, from 22 to 34, and her block-ships of 60 guns each from 4 to 9. It is necessary that we should notice this superiority in steam-frigates on the part of France over Great Britain, which, in the event of hostilities, might form a serious detriment to this country, especially in relation to the interruption of commerce. On the other hand, the French steam-corvettes and sloops, which, in 1852 were 31, are now only 22; while those of Great Britain, which in 1852 were 59, are now, including 7 vessels since reduced from frigates to sloops, 82; our screw floating-batteries are 8, as against 5 French; our screw gun-vessels and other small vessels are 53, whereas the French have 93; our screw gun-boats are 162, and those of France 28; and the whole steam navy of Great Britain now amounts to 464 vessels, while that of France numbers 264.

As regards sailing-vessels England, it will be seen, still possesses a great superiority over France. England has 35 line of-battle ships, of which 6 are proposed to be converted into steam-ships; of the remaining 29, only 13 are considered by the Surveyor of the Navy effective as sailing-ships; and, in his opinion, if it should be deemed expedient to convert any of them, they are convertible only into frigates; France has 10, of which only two are convertible; England has 70 frigates (of which 27 only are reported by the Surveyor as effective sailing-ships). France has 32, of which it is supposed that 9 or 10 will be converted into steam-transports, the remainder being too old for conversion; there are in both countries several other vessels which, being too small for conversion, it is not necessary to notice. The total number in the two sailing navies is, England, 206; France, 144.

The following statement prepared from the French estimates and accounts, shows the expenditure for naval purposes in France during the series of years as compared with our own, as also statements of the actual expenditure in pay, victualling, and clothing for the naval service of both countries, during each year since 1852; of new works, improvements, and repairs of docks, and of labour and material; the total being as follows:—

England in the Seven Years.	£
Victualling, pay, clothing	25,331,264
New works, repairs, &c.	3,441,721
Labour and materials*	24,406,601
	£53,179,586

France in the Seven Years.	£
Victualling, pay, clothing	17,755,817
New works, repairs, &c.	2,819,901
Labour and materials and ordnance	18,369,666
	£38,935,384

	Acres.

In conclusion, the reporters again call their Lordships' attention to the weakness of Great Britain in steam-frigates, and then add, "The large increase of the French steam navy, since 1852, in line-of-battle ships and frigates, has been effected mainly by the conversion of sailing ships. The Surveyor of the Navy reports, that there are at least 19 ships of the line in the English Navy convertible, of which he proposes to convert 6 into steam-ships of the line, and 13 into steam-frigates. We append a return of the number of vessels launched in the dockyards in England since 1852; which also shows the number of shipwrights employed on building ships, as compared with repairing ships. The number of men required to convert a three-decker into a 90-gun steam-ship is stated to be five-eighths of the number required to build a new 90-gun steam-ship. The chief difference in the cost of conversion arises from the saving in materials. The cost of converting a line-of-battle ship of 90 guns is estimated at £25,000, and the cost of building the same, at £105,000, but the latter will, of course, be a far more efficient and durable vessel. The process of conversion, on the other hand, is speedy, as compared with that of building. The present seems a state of transition, as regards naval architecture, inducing the French Government to suspend the laying down of new ships of the line altogether, and it is more especially so with respect to artillery. The late invention of "Armstrong's gun," it has been stated to us, may supersede the use of the ordinary ship's guns, and possibly affect even the size and structure of ships of war. We therefore venture to suggest, for your Lordship's consideration, whether, if the force in the dockyards were to be used next year in the conversion of ships of the line and frigates, as far as the available dock accommodation will admit, the most useful results might not be attained at a comparatively small expenditure.

We beg, also, to direct your Lordships' attention to the prospective outlay contemplated by France, to complete her steam navy and her naval establishments. According to a report of the Minister of Marine, prefixed to the French Navy Estimates for 1859, it appears that it is intended to raise the French steam navy to 50 vessels of war of various classes, built after the best models, with engines of full power, in addition to 72 steam-transports, and to complete the building, in the several military ports, of the dry docks and factories indispensable to meet the requirments of the new steam fleet. The expense of these works is to be spread over the period from 1859 to 1871. The money to be appropriated to these works is also stated in the Minister's report; he proposes that the annual grants for labour, materials, armament, new works and repairs, up to the year 1871, shall be raised to the sum of £2,600,000; he estimates that £1,920,000 of this sum will be absorbed in the "annual consumption of the steam navy, works of maintenance, and the renewal of existing materials," leaving the annual average sum of £680,000, for the increase of the fleet and the extension of the naval establishments. The sum which France intends to devote to the latter purposes up to 1871, when the fleet will have reached the limit of its proposed extension, amounts therefore to £8,840,000.

The proposed annual grant of £2,600,000, would amount, in 13 years, to £33,800,000. Maintenance and renewal will absorb nearly three-fourths of this sum, leaving the above sum of £8,840,000, or rather more than one-fourth, to be devoted to the increase of her strength in ships and naval establishments. The sum granted in England by Parliament, in the year 1858-59, for the same services in the navy estimates, including £757,000 for naval ordnance and ammunition provided for in the army estimates, amounted to £3,754,000, being £1,154,000 in excess of the increased annual grants proposed by France for the next 13 years. Before we can ascertain how much of this sum, or of any smaller sum, can be considered applicable to the increase of our steam-navy and naval establishments, it will be necessary to fix the strength of the fleet to be maintained in commission; for it is clear that the larger the number of ships in commission, the larger must be the sum for maintenance, outfit, and repairs; and consequently, the smaller will be the margin available for the increase of our existing force. France founds her calculations upon a return to her peace establishment of 1852; the number of her ships in commission for 1859 being 152, against 175 in the year 1852; and the number of seamen afloat being 25,784, against 25,016 in 1852. Our position is very different. On the 1st of December, 1858, our ships in commission, and their complements, as compared with 1852, were as follows:—

	Ships.	Guns.	Complements.
1st December, 1858	267	4,649	47,953
1st December, 1852	203	3,584	36,372
Increase	64	1,065	11,581

This number is exclusive of a further increase of 3,302 marines on shore, including 1,800 employed on shore in China, also of 3,880 seamen employed in the coast-guard on shore, making a total increase in 1858, as compared with 1852, of 18,763 seamen and marines. It is clear, therefore, that although the sums voted on our navy estimates for labour and materials are greater than those expended in France, a much smaller proportionate surplus is available for building new ships.

* N.B.—The expense of ordnance for the navy is excluded but the estimated cost may be taken at about £4,000,000 for England in the same period.

† This includes 284 acres, St. Mary's Island, adjoining, but not included in Chatham dockyard.

The number of passengers who used the horse railroads of New York and Brooklyn during the past year, amounted to 34,633,525, and the gross receipts therefrom to 1,731,676 dollars 25 cents. This gives a daily average of 94,882 persons, showing the money taken every day in the year to average 4,744 dollars 10 cents. These railroads, which are tracks laid down in the streets, the rails being made of a peculiar form to avoid the objections of the ordinary rail, all concentrate in the business part of New York, and take the most of the travel to and from it. Can we not imitate this with immense advantage in London?

MEETINGS FOR THE WEEK.

Mon.—*London Inst.*, "On Ballet Music," by John Ella, Esq., at 7 p.m.

Tues.—*Society of Antiquaries*, Annual Meeting.

Inst. Civil Engineers—I., "On the Tyne Docks at South Shields, and on the Mode adopted for Shipping Coals," by Mr. J. E. Harrison; II., Discussion upon Mr. Kingsbury's paper on the Victoria (London) Docks, and upon Mr. Harrison's paper on the Tyne Docks, at 8 p.m.

Royal Inst., Lecture on "The Nature and Extent of Geological Enquiry—Relation of Geology to the other Sciences—General laws of Structure recognized in the Earth—Submarine origin of most Rocks," by James Morris, F.G.S.

Wed.—*Royal Agric. Society*, General Meeting at 12 noon.

Thurs.—*Chemical*, 8 p.m.

Royal Inst., "On Art—The first period—The birth—The development—Art as writing—As history—Egypt, Assyria, The Jews, and other Asiatic Nations," by A. H. Layard, at 3 p.m.

Linnean, at 8 p.m.

Royal Society, F. Elefánty, on "Proposition upon Arithmetical Progression;" Prof. Matteucci, "Sur les Propriétés électriques des corps isolants."

London Inst., "On Commercial Law," by G. W. Hastings, Esq., at 7 p.m.

Frid.—*United Service Inst.*, at 3 p.m.

Royal Inst., Robert Druitt, M.R.C.P., "On Houses in relation to Health," at 9 p.m.

Sat.—*Royal Inst.*, "On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

Proceedings of Societies.

INSTITUTION OF CIVIL ENGINEERS.

April 12.—Joseph Locke, Esq., M.P., President, in the chair. The whole of the evening was occupied by the discussion of Mr. McMaster's paper, "On the Permanent Way of the Madras Railway." It was remarked that for India and other similar countries it was desirable to aim at obtaining the smallest number of pieces and simplicity of parts. The arrangements should be made with a view to guard against peculation, as well as to the best mechanical construction, for the natives were apt to steal fishing plates and bolts. It was further urged that the quality of the materials and the machinery to be sent to India and other distant places should be carefully attended to, as the heavy charges for freight and shipment formed a large portion of the expense. It was thought that sufficient stress had not been laid on the importance of utilizing, as far as possible, the resources of the country in which the works were being carried out. In Ceylon, for instance, there were forests of almost interminable extent, which might be made available. Eighteen different samples of timber had been examined, at least nine of which were applicable for railway sleepers, in situations where they would be exposed to extreme variations of atmosphere and weather. The drainage of railways in tropical climates was a matter of the utmost importance, as the ballast was liable to be carried away by the heavy periodical rains. In reply it was intimated, that the necessity for sending out timber sleepers to India arose from the circumstance, that the supply there could not be relied on. There was great difficulty in determining the precise value and quality of woods in foreign countries, especially when such practices are carried on as steeping the wood in order to deceive, as had been the case in Madras. In closing the discussion, the great diversity of opinion that still prevailed on this subject was commented upon. Every one appeared to think his own plan the best, and naturally preferred to be guided by his own experience rather than by that of others. As to the question of the durability of timber, whether prepared or not, and, if prepared, then by what process, few persons were able to obtain reliable data as far back as twenty or thirty years. The Minutes of the Institution would contain a variety of opinions on this subject, but it was doubted whether the question could be solved, or whether there could ever be universal agreement as to what was the best system of permanent way to be used under all conditions.

After the meeting, Mr. Curtis explained a system of Axle Boxes, in which, by centrifugal action, the oil was constantly thrown over the upper side of the axle, and descending slowly upon the axle was returned again to the oil chamber. As soon as it had passed the axle, a piece of thin porous flannel, placed at the bottom of the oil chamber, was found in practice to answer as a filter to receive the parts of the metal, or other residuum, resulting from the working of the boxes. These boxes were now at work on eight railways in England and on one in France. They had been in use for upwards of eighteen months; in some cases they had run for two months without any oil being applied; but the ordinary practice was to introduce about a wine glass full of oil to each box once a week.

SOCIETY OF ARTS.

April 25.—The Annual Exibition of Inventions was opened on this day.

April 27.—Mr. Robert Hunt, F.R.S., in the chair, Mr. John Arthur Phillips read a paper "On the Metallurgy of Lead." The author began by describing the principal ores from which the metal was usually obtained. The various localities where this ore was found were enumerated. Mr. Phillips described in detail the construction of the reverbatory furnace, and pointed out the chemical changes brought about in the ores by exposure to its action, and concluded by stating that it is in the treatment of ores of good produce that the reverbatory furnace and "Scotch-hearth" are to be preferred; but for working minerals of a low per-centage the blast furnace may generally be substituted with advantage; the slag-hearth, from the amount of fuel consumed, and loss experienced, is a somewhat expensive apparatus, and might in many cases be advantageously exchanged for the Castilian furnace.

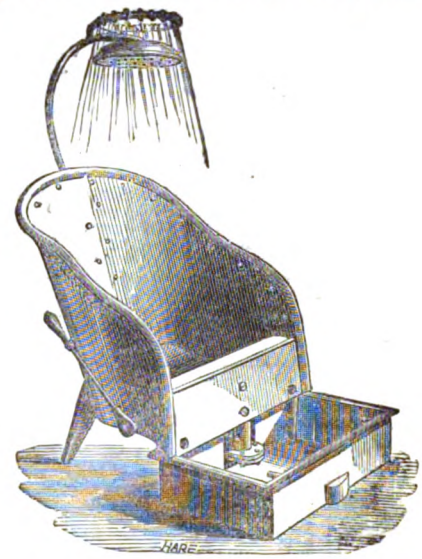
HOW GREAT GUNS ARE MADE.

In our last week's number something was said about the quality and character of iron requisite for producing sound heavy guns, and the experiments made at Woolwich during the last two years were referred to. This week we propose to give further information on the important subject, and more especially in reference to the furnaces and other appliances connected with the Woolwich factories. A 68 lb. gun, when finished, is 17 feet long, 28 inches in diameter at the breech, and weighs 95 cwt. As guns of this description are cast vertically, and require a "dead head" of considerable magnitude in order to insure sufficient density, it may be imagined that the furnaces are matters of important consideration. In practice it was found advisable to use two furnaces in the melting of a sufficient quantity of iron for the production of one such gun as we have described. The Woolwich furnaces would each hold sufficient molten metal for the casting of one gun, but as it was not possible to charge with ten tons of pig iron at once, it was found better in every way to charge two furnaces with five tons, and melt simultaneously. The quality of the iron produced in this way was found to be superior to that resulting from one furnace, when a portion of the charge must have been melted first and the remainder afterwards. Repeated tests proved this fact to demonstration, and it is a practical point of much consequence. The Woolwich furnaces are partly constructed of Stourbridge fire-brick, but the beds are of a different material. The throwing in of old "carronades," "dead heads," and "pigs," was found to chip off, or to crack and destroy the fire-bricks, and a substitute for these in the construction of the furnace beds had to be found. A cheaper substance, and one which admits of easy repair, is now used. It is composed of equal parts of glass-grinder's sand and blackfoot sand. The former is the refuse from the Thames patent glass works, and contains a considerable admixture of fine particles of glass, and the latter is obtained from the sand pits at Charlton. These are amalgamated, rammed hard upon the foundation of the furnace, and after the application of heat form a vitrified surface impervious to liquid iron. The sand furnace bed is in point of efficiency and economy immeasurably superior to that of fire-brick, and we recommend it strongly. With respect to the dimensions of the furnaces, it may be stated that they are about 22 ft. long, from centre of fire grate to centre of chimney; 5 ft. 2 in. wide; and 2 ft. 6 in. in height from bed to crown. The fire-grate is 5 ft. 2 in. square, and open for the admission of air at the end of the furnace, and the chimney is 60 ft. in height and 2 ft. 6 in. square. The furnaces are always heated before receiving their charges, and when the latter are sufficiently fluid and hot, the molten streams from two furnaces, as we have stated, are made to flow through separate channels into one reservoir. Here they mingle and blend for a little time in one harmonious whole, so as to equalise any difference of temperature which may have existed prior to their being tapped. Metal is now ladled in small quantities from the reservoir for the purpose of casting testing bars, and a sluice door being opened the molten ocean courses its way down river-like into the centre of the gun mould, which is placed vertically, and muzzle upwards, to receive it. Scoria and other impurities float upwards as the metal rises, and great precautions are taken to prevent their flowing with the iron into the "trunnions," which they would weaken, and thus make the whole casting useless. When the metal reaches to within a few inches of the guide shute, the flood-gates through which it flowed are shut for a minute until the shute is removed, and then again opened for the complete filling of the mould. In cooling there is a great subsidence of the metal, especially in the centre, but the hollowness thus produced is in the dead head entirely, and by no means deteriorates the gun. Everything is suffered to remain *in statu quo* for about three days and nights after the pouring operation. The mould is then opened and the casting, usually perfect, is prepared by lathe and boring mill for proving, and mayhap for battle. Such is some account of the gestation and birth of a great gun, and which in these non-piping times of war may be acceptable to the public generally, and certainly must be to the scientific reader.

Erratum.—"Northerton," in last week's Magazine—subject, Gun-making at Woolwich—should be "Netherton."

GRIFFITH'S PATENT CHAIR BATH.

The illustration below shows one of the most useful improvements that we have seen for some time in articles of domestic convenience. It is the invention of Mr. Griffith, the inventor of the Griffith screw propeller, and it will, no doubt soon come into general use, as by the arrangement, the inconvenient amount of space occupied by any ordinary bath in a bed or dressing room is



no longer necessary, for when the bath is not required, the foot bath is placed under the chair, and covered over with any ordinary furniture. The whole will then form a complete easy chair. The covering can be removed instantly, and it is at once ready for either a foot, hip, or sponging bath, and if the bent pipe and rose head shown are also fixed, it can be used as a shower bath.

It has long been a desideratum in Paris to obtain some accurate means of checking the drivers of public vehicles; the problem being to produce an instrument that would register the hours and minutes during which the vehicle was employed. This has been very cleverly attained by M. Giaccobi, Lieutenant-Colonel in the *Garde de Paris*. He places a time-piece, enclosed in a cylinder, under the seat of the driver; the cylinder carries a dial-plate, in which is a circular paper divided by minutes. The time-keeper is provided with two needles, one of which is provided with a point perpendicular to the paper circle. Around the dial of the time-keeper and the paper dial is a frame, which can only be moved by the opening of the door of the carriage. By the movement of this frame the paper dial is pierced by the needles showing thus the exact minute at which the door was opened. The other needle performs a double office; it shows the persons within the carriage the time at which they entered it, and how the time goes; and it likewise draws a black line during the time the carriage is in motion. The invention is very ingenious, but it does not show the distance passed over, so that it is not a register of mileage.

REDL'S CONE TELEGRAPH FOR THE NAVY AND WAR DEPARTMENTS.

(*Concluded from p. 269.*)

THE DUAL SYSTEM.

This System is so called because by it *two* symbols can be made to indicate any disposition of the four Cones. And it can be used with two different sounds, or two different visible objects.

The Dual System by Sound can be used with a Bell, Drum, Bugle, Steam Whistle, or other instrument, capable of producing a single sound, and two quickly repeated sounds. The single sound is used as a *positive*, and when made, represents a cone to be open, and may be denoted on paper by a X. The double sound is used as a *negative*, and when made, represents that the cone referred to is closed, and may be represented on paper by an O. Four successive *positives* or *negatives* complete a series or figure.

By using the fingers again for illustration, we have the code represented as before.

The application of the five *auxiliary signs* and of the Alphabetical numbers and pendants, is the same as in the Cone System, except the "*Substitute*," which is used only as an affirmative answer.

The "*Preparative*" and the "*Stops*," are repeated in reply, by the receiver of the signal, but the other sounds need not be repeated should it confuse the ear.

But great advantage is found both as regards *celerity* and *correctness*, by abbreviating the sounds for figures 1, 2, 3, and 4.

The figure 1, is denoted by a *positive* (*single* sound);
figure 2, is denoted by a *negative* and *positive*;
figure 3, is denoted by a *positive* and *negative*;
figure 4, is denoted by two *negatives* and a *positive*.

The Dual System by Sight can be used with any *two* different visible symbols, as a flag and pendant, or two different articles of clothing; or for a distant signal, a single pair of cones or sails; or for night signals, two different coloured lanterns, or a single and a double common light.

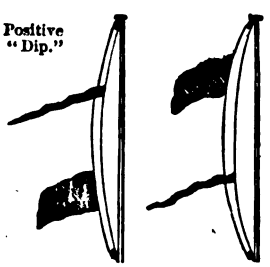
In the first case, the pendant may represent the *positive*, and the flag the *negative*, but where other articles are used *without* any preconcerted arrangements, it follows as a matter of course, as the "*Pendant*" must be made, that the article *first* shown above the other is the *positive*, and the other article the *negative*.

This system is essentially the same as that already explained for *sound*, the *positive* representing to the sight the *open*, and the *negative* the *closed*, state of the cone. And is also capable of considerable abbreviation, by omitting the *negatives after* the *last positive* in the series or figure.

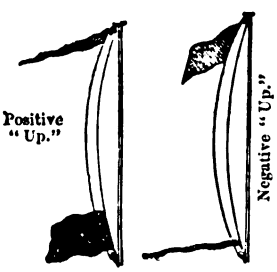
For instance, let the two symbols (suppose a flag and pendant) be stopped on to the two different parts of the same signal halyards, so that as one goes up the other comes down, and the position of each may be determined by that of either.

Square.

When they are "*square*," they are about 20 feet (more or less) from the mast head, according to the distance to be signalized and the height of the mast, and in this position they have no meaning.

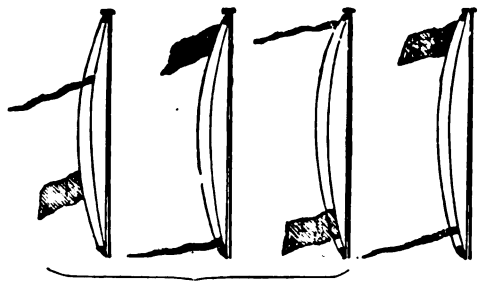


When the *positive*, or *negative*, is shown at the "*dip*," a short distance *above* the other, it denotes a *positive* or *negative*.



When the *positive* is shown at the mast head or "*up*" it denotes, that *the last positive in the figure* is made and that the series or figure is complete; the hoists following pertain therefore to another figure.

When the *negative* is shown close "*up*," it is the duplicate of the *hoist* immediate preceding it.



¶ 1

Thus—to make (¶ 1) "Pendant 1."

For ¶ { 1st hoist *positive* at the "*dip*" as common positive.
2nd " *negative* "*up*" as duplicate of ditto.
3rd " *positive* "*up*" as last positive of the series.

For 1. Hoist *negative* "*up*" as duplicate of ditto.

The "*Preparative*" is made by causing the two symbols to pass each other rapidly and frequently, and is used to correct mistakes, &c., as explained in the Cone System.

Positive. Negative. Substitute.

In the Dual System by a Single Pair of Cones where the Upper Cone open represented the *positive*,
the Lower " " *negative*,
Both Cones open together " *substitute*,
the communication might be abbreviated by using the "*substitute*" as the *last positive in the series*;—care being taken to see the receiver's Cones closed before the sender repeats the hoist.

Similarly in the Dual System applied to Lights for Night Signals, one common light might represent the *positive*, and a red light or two common lights the *negative*, and both together the *substitute*.

With common lights only, the system as explained for sound might be used.

But with a red and a common light, the abbreviated system as explained for flag and pendant might be used.

The Dual System may also be used with one Symbol in two different places, for instance with a *ball on one mast*, let the "*up*" be the *positive* and the "*dip*," the *negative*; or *with a ball on two masts* let the ball at the Main be *positive*, and at the Fore or Mizen be *negative*; or *at night* let a red light *above* a stationary common light be *negative* and *below* the common light be *positive*.

IMPROVEMENT IN SCREW SHIPS.

M. A. Normand, the well-known ship-builder of Havre, France, has patented in this country an improvement in the construction of screw ships. In carrying out this invention he says—and we give his own words, although they are not very intelligible:—"To the part of the stern comprised between the two stern posts, on each side of the central plan of the vessel, and on a proper extent, a segmental form, either convex or concave in cross section, or a plane surface, whichever will best suit the shape of the stern of the ship. Secondly, I close the bottom opening of the well-hole by sliding lateral doors or shutters (of wood, or metal, or both), taking the form of the outside of the vessel, and moveable either from within or from the deck of the vessel, so as to recede or approach each other. If thought desirable the sliding doors may be divided into several parts, and either worked altogether or separately. They may be opened or closed by means of endless chains, racks, and pinions, screws, or any other means found most suitable according to the size, form, and arrangement of the vessel to which they are fitted. I also propose to alter the usual shape of the opening of the well-hole, making it follow the profile figure of the screw when viewed from the stern, the screw being turned to bring the central part of its blades into a vertical line, which is the position it will be required to take when it is raised or lowered. This novel arrangement has the advantage of reducing, as far as is practicable, the internal size of the well-hole, and consequently the surface which the sliding doors have to cover, and so give a greater length to the guides for the shutters."

The unsettled state of home and foreign affairs is reported to have exercised an injurious influence over Sheffield trade. A new rolling mill has, however, been started at Messrs. Hopper's Britannia Iron Works further north. Most of the India lines are using the conical-necked twisted railway spike which Mr. Hopper manufactures in considerable quantities. His works are now turning out about 1,000 tons of these fastenings.

* In making Ships' Names, use "Stop" after ¶ with number of distant signal.

† Nautical time (24 hours, from noon to noon) is used.

‡ *North* being 32, N. by E. 1, N.N.E. 2, and so on.

THE CONSERVATION OF FORCE.

Gentlemen,—I am one of those common-place persons who cherish a lively faith in the common saying, "Brevity is the soul of wit." I participate in the antipathy which the illiterate feel towards long sermons, prosy lectures, and big books. Is this a proof of weakness? Does it show the man of low mental status if he prefer Emerson to Swedenborg—an express train to an omnibus—an article in the *Times* to a German treatise on politics? My favourite principle is the principle of economy. I like to have ideas communicated to me in as few words as are consistent with clearness of expression. It may be a proof of small intellectual endowments, but I must avow the truth—I have a disgust for the effort required to hunt a solitary forlorn idea through pages of verbiage as that needle has to be hunted for in a bundle of hay of which the proverb speaks. It may be that I am unequal to the necessary effort of attention, and therefore have failed to discover the great scientific truths which M. Seguin seems to think are expressed in his "*Mémoire sur l'origine et la propagation de la force.*" This gentleman appears to be devoted to a law of economy just the inverse of that which I approve. His object is, one would think, having caught a stray notion, to load it with as much misty language as it can possibly be made to carry; and he is an accomplished professor of what Moliere calls,—

"L'art de ne vous rien dire avec de grands discours."

A full analysis of this Mémoire would require more time than I can give, and more space than you can spare. I will confine my attention, therefore, to M. Seguin's remarks on the subject. He says:—

"Take as an example, the attraction exerted by the earth upon a body falling from rest during a second of time; we know that, in this case, the velocity of the falling body, beginning at zero, gradually increases after the manner of an arithmetic series, till at the expiration of the second of time a velocity is attained such that if gravitation were then to cease to act, and the velocity were to continue constant, the body would move through a distance of ten metres every second. From this it is deduced that as the velocity of the body began at nothing and arrived at ten metres at the end of the first second, the mean velocity during that second was five metres; and therefore the body fell through a space of five metres in the first second. Further, as the velocity of the falling body continues to increase, the distance described by the body from the commencement of its fall, represented by the sum of all its velocities, will vary as the square of the velocity. Again, when two bodies, by virtue of mutual attraction, move towards each other the velocities which they acquire are inversely proportional to their masses. Hence it follows that if the number or the density of the molecules which form the earth were suddenly increased a thousand times, and just at the instant when a body is projected upwards with a velocity of ten metres, it would be reduced to rest after rising through a space equal to one thousandth part of five metres, or five millimetres, and the time occupied would vary as the square root of the ratio of the two masses." • • •

"Now let us suppose that the body, instead of losing in motion in whole or in part by the gravitation of the earth, parts with it to some other body with which it comes into collision. It is evident that if the two bodies are not broken by the impact, they will undergo a mutual compression. The molecules of which the bodies are composed will be forced to change their distances apart, as well as their relative positions. And as this requires a certain amount of force, the part of the force necessary to produce the compression of the body struck must be furnished by the impinging body. This body, then, must lose a part of its motion in the same way that it would if it had moved through a small space in opposition to gravity. This compression and communication of motions continue till the body striking has, according to its nature, exhausted all the motion which it is capable of transferring to the body on which it impinges. The two bodies will continue to move in the same direction, or in contrary directions, with the amount of motion with which the impinging body was previously endowed, diminished by any which may have been absorbed in separating the parts of the bodies, or in changing their form, or any which may have passed into the form of light, heat, or electricity."

From this we are conducted, through more words than I care to attempt to translate, to the following proposition:—

"The force which, during the impact, passes from one body to the other, follows the same laws which govern the motion of falling bodies; and the effects produced ought therefore to be measured by the product of the mass, and the square of the velocity."

That is, when two bodies impinge and undergo a change of motion, the *vis viva* gained by the one is equal to the *vis viva* gained by the other. The ordinary theory is, that the momentum lost by the one body is equal to the momentum gained by the other. M. Seguin severely criticises mathematicians in general, and M. Poisson in particular, for adopting the latter proposition. Now, it is my humble opinion that Poisson and the others are quite right, and that M. Seguin has fallen into a most transparent error. M. Seguin is quite correct when he states that the same laws of motion apply to the collision of bodies as to their motion under the action of gravitation. But herein he promulgates nothing new—nothing which would not, with perfect consistency, be assented to by any disciple of Poisson; for it is in accordance with these very laws that M. Poisson has conducted his investigation. M. Seguin adopts the ordinary account given of the fall of bodies under terrestrial gravity; and, therefore, agrees to the ordinary laws of motion. Of the two following equations he perfectly approves:—

$$v = g\,t \qquad (1);$$

$$s = \tfrac{1}{2} g\,t^2 = \frac{v^2}{2\,g} \qquad (2);$$

Where v = velocity acquired in t seconds by a body falling from rest, s = space described in same time, and g = the accelerating force of gravity = 32·2 feet.

These equations apply to the motion generated in a falling body by terrestrial gravitation. They are not independent equations; for, either being given, the other can be deduced from it. These two equations are independent of the mass of the falling body, because terrestrial gravitation produces the same velocities in all bodies falling from the same point during the same time. But, introducing the mass of the body, and giving the law which these equations express a general interpretation, they would stand thus:—

I. Let M = mass of the body, P = force in pounds acting on it and setting it in motion, V = velocity generated in time, t; and suppose m and v to be the mass and velocity of another, acted on by the same force P, during the same time t, and under similar circumstances; then

$$M\,V = m\,v = P\,t;$$

that is, the momenta are equal.

II. Now suppose U and u to be the velocities generated in the two bodies by the same force P, acting through the same space s; then we get

$$M\,U^2 = m\,u^2 = 2\,P\,s;$$

or, the *vires vivae* are equal.

It must be understood that M. Seguin by no means questions these two propositions, but he misapplies them. How he can have made this mistake I cannot understand, for it seems to me that these two propositions, in conjunction with the law of action and re-action, leave no room for mistake in the general treatment of the dynamical phenomena produced by the mutual action of any two bodies. For any kind of mutual mechanical action of two bodies on one another we have the two laws already cited, and the law that their mutual attraction or repulsion are equal in amount, but opposite in direction. It is quite axiomatic, too, that when two bodies exert any reciprocal action on each other, the bodies are subjected to the action during precisely the same time. Thus, when two bodies strike one another, the blow is of the nature of a very great pressure acting during a very short period of time. But this small time during which the pressure acts is the same for one body as for the other. Hence equation 1, and not equation 2, applies to the collision of bodies, as it must apply to all mutual actions. Thus, in impact the impinging bodies are acted on in opposite directions by the same pressure during the same time. Hence it follows, from the laws which M. Seguin himself adopts, that the change of momentum in the one body is equal and opposite to the change of momentum in the other. The sort of case to which the second equation applies, may be illustrated by the stopping of a railway train by means of the break. If it be required to stop trains having various speeds within a given distance of the spot whereon the break is first applied, then the resisting force applied by means of the break should vary with the weight of the train and the square of its velocity, or in other words with its *vis viva*. But this is a case very distinct from the impact of two bodies, because in the latter, not the space through which the impulsive force acts, but the time during which it acts is the same for the two bodies. If it were desired to stop the various railway trains within a given lapse of time after the application of the break, the resisting force must vary as the weight of the train, and as the first power of the velocity, or, in short, as the momentum.

His erroneous views on impact are not the only errors which M. Seguin's paper contains, but I shall spare all parties further reference to them at present. I am, gentlemen, yours, &c.,

A Mechanic.

TELEGRAPHS TO CHINA AND AUSTRALIA.

To the Editors of the "Mechanics' Magazine."

Gentlemen,—The immense field of commerce now opened to England in China, and the increasing prosperity of the British possessions in Australia, make it a matter of no small importance that the distance, *in time*, between China and England, and between Australia and England, should be diminished to such a degree as to afford merchants in China and in Australia better means of transacting business than they now have, alienated, as they are, from the electric world. We are promised, at no very distant period, an electric communication with Calcutta and Madras. It must be evident to every one who takes an interest in such matters that a comparatively small expense—to that of the Red Sea telegraph—would connect Calcutta or Madras with Singapore; Andaman's Islands forming a most convenient point for a "station," aided, if necessary, by a station on one of the Nicobar Islands. The distance from Calcutta to Singapore being about three-fifths the distance of the coast of Galway from America, all risk as to the laying of a cable is comparatively *nil*. The extension of the line to Hong-Kong or Canton, on one side, and a convenient point on the Australian coast, on the other, would soon be accomplished by the aid and eager co-operation of those who have interests at stake in those parts of our small earth. As you are never backward in publishing what may be of practical use to the community at large, I hope you will publish these suggestions from one whose means will, unfortunately, only admit of his investing *hundreds* towards the achievement of such a scheme.

Before concluding, I beg to remark that the Atlantic Telegraph would now be in perfect working order if steps had been taken to obviate the total want of longitudinal expansion, or elasticity. This could easily be done by placing, at distances (which should be regulated by the length of the cable and geodetic formation of its resting-place), *conductive spring joints*, which would add a *little* to the bulk and first outlay, but would ensure the wanted elasticity and success of the enterprise.

I have not been so statistical as I should have wished, owing to my being temporarily separated from references; but I shall feel some satisfaction if my remarks are appreciated. I enclose my card, and remain, Gentlemen, your obedient servant,

Time is Money.

Vienna, March 31st, 1859.

His Majesty the Emperor of the French has presented Mr. Henry Bradbury with a magnificent gold snuff-box, surmounted by the Imperial crown and cypher in brilliants, in token of his admiration of Mr. Bradbury's system of "nature printing."

Experiments have been made at Vienna, Dresden, and other places in the use of tungsten or wolfram in the alloying of steel, and some extraordinary results are stated to have been achieved. It is said that steel alloyed with 20 per cent. of tungsten produces a mixture which, while it retains all the general qualities of steel, is so excessively hard that tools made of it will cut, without difficulty, the hardest cast steel. Large quantities of the new alloyed metal are said to be in preparation, and a company is about to be formed to work the discovery.

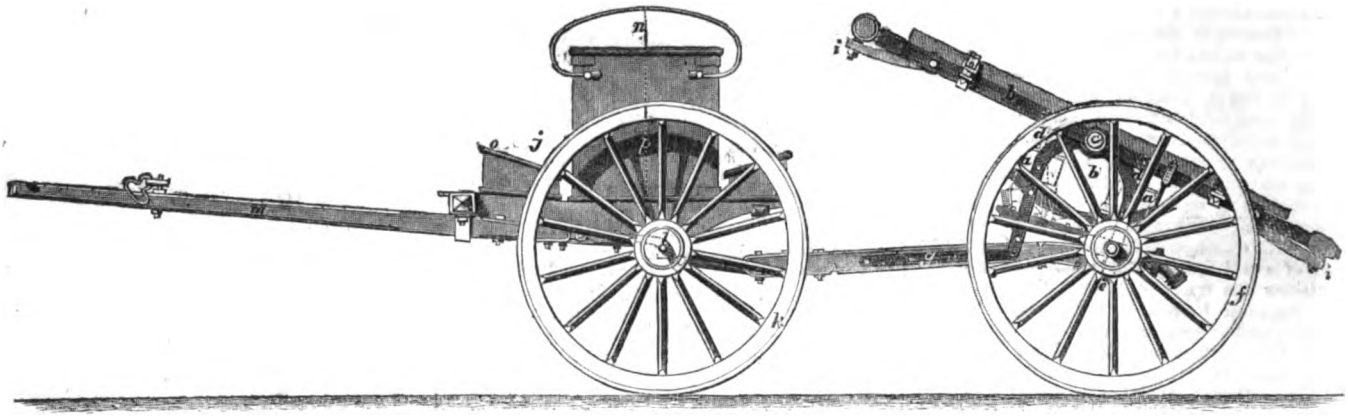
CAPTAIN FOWKE'S PATENT FIRE-ENGINE.



Captain Francis Fowke, R.E., who is well known as a scientific man, has patented the peculiar arrangement of portable fire-engine which is represented in the annexed engraving, and which is capable of being easily transported either by manual labour or horse power, and forms a compact and powerful fire-engine, the ordinary wood or metal cistern hitherto employed being dispensed with, whereby the efficiency and lightness of the engine are greatly increased. "The improved engine consists," says Captain Fowke, "of a pair of single-acting force-pumps *a*, *a*, fitted with metal valves, and a suction and delivery air-vessel *b*, and to insure the proper action of the suction air-vessel (not shown in the engraving) an additional valve is provided at *c*. The pistons or plungers are connected to the slings *d*, *d*, by a joint in the centre of the body of the plunger, so as to prevent any objectionable vibration, by which the ordinary guide-rods are dispensed with, and the pistons are enabled to be instantly withdrawn, thus affording immediate access to the suction valves. The delivery air-vessel *b* is so constructed that, by unscrewing the part to which the hose is fastened, immediate access is also obtained to the delivery valves. The pumps are fixed direct to a wrought-iron cranked axle *e*, mounted on two high-running wheels *f*, and having a wooden pole *g* attached, to the end of which a cross-bar (not shown in the engraving) is fitted, which serves as a drag handle when the engine is drawn by men, and when working rests on the ground with two or more men standing on it, their weight preventing the engine from moving. The wrought-iron frame *h* for working the pumps are fitted with swivel sockets *i* to receive the working handles, which are parallel with the axle when in use, and when not in use placed at right angles to it, being still supported by the swivel sockets, and serving as poles to carry the suction pipes. The fore-carriage *j* may be detached from the engine, and may consist of a pair of high wheels *k*, mounted on an axle *l*, and suitable shafts *m*, with driving-seat *n*, footboard *o*, and box *p*, to contain implements. The axle may be fitted with a reel which revolves freely upon it, and on this reel the whole of the hose is coiled. When used merely as a hand engine, the fore carriage may be dispensed with, and the hose and implements placed on the engine."

CAPTAIN CONNOLLY'S RIFLE REST.

FIG. 2.

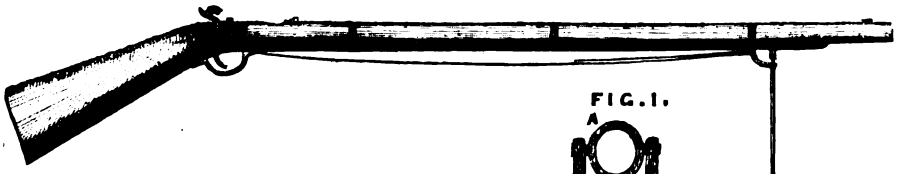


FIG. 1.

We have been favoured by a friend with the following description of the nature and advantages of a new rifle-rest lately invented by Captain Connolly, R.N.; it was drawn up by the inventor. Captain Connolly, in this description, scarcely does credit to his simple and promising invention. The ramrod itself is employed to form the rest, by fitting it with a swivel radius pipe (frequently used for the ramrods of pistols). When the rod is pulled out sufficiently to release the end from the fixed pipe in the stock, it assumes a hanging position, as seen in Fig. 2 of the annexed engravings, and on lowering the rifle so as to allow the end of the ramrod to rest on the ground, a really efficient rest is provided for the piece. A socket, or cup in the stock, receives the upper or butt end of the ramrod, which adjusts itself to its work; and it is this simple self-acting principle which constitutes the beauty of Captain Connolly's invention. The following are Captain Connolly's remarks:—

This rest is made by a swivel screwed on to the lower part of the upper band of the rifle (*vide* sketch Fig. 1), the upper swivel, *A*, being sufficiently large to give the ramrod full play, and being slightly ovalled if necessary, to fit flush into the stock when not being used and the ramrod is returned. A small brass cup or socket, large enough to receive the head of the ramrod, is let into the stock above the band—the ramrod being then let fall through the swivel, and the head inserted into the cup, a most perfect rest is obtained.

It is by no means indispensable that the head of the ramrod should rest in the cup; it is nearly equally steady butting against the slings or any other part of the stock; indeed, for a sportsman firing from the kneeling position, it is better to slope the ramrod forward, and let the head of it rest against the upper band. I merely insert the *cup* into the stock, because a small incision must be made to receive the swivel *A*, when not being used, at the same time it steadies the ramrod more, and makes the rest more perfect when the cup is used.

The advantages of this rest I conceive to be—

1st. Its extreme lightness and simplicity, so that it is little or no encumbrance to the rifle, even should it not be used, as it would not be in close quarters, or on common occasions of skirmishing. Some men, indeed, would probably prefer never to use a rest; still I think even if twenty per cent. fire better with it, it is an object gained, and this rest is so exceedingly light and simple, as to be but little encumbrance to the rifle should it not be used.

2ndly. I have observed in firing that it is in the *elevation* more than in the *direction* that most misses occur, from a habit some men have of throwing their heads back when firing, by which the piece is raised, or the act of pulling the trigger, however gently, causing the muzzle slightly to fall. Both these errors are entirely avoided by using the rest, for the muzzle resting entirely on its support, both hands are brought near the trigger guard, and the elevation, therefore, at all events, is not likely to be disturbed by the act of firing the piece.

3rdly. It is in long distances, *i.e.*, from 600 to 900 yards, that a rest appears to me of so great advantage, a man having to raise his head so considerably at those elevations, as to lose in a great measure the equilibrium of body which is assured by the present kneeling position.

I have myself found this to be the case; it was, indeed, from observing this great defect, and skirmishers being instructed to use every possible means of obtaining a rest at long distances, that caused me to turn my attention to this important desideratum in the rifle; especially as men are taught to form a rest, by inserting the screw end of the ramrod under the middle band of the rifle, with the head of it resting against the person; a plan, in my mind, as inefficient as it is dangerous to the soldier.

4thly. By means of this rest, a disabled man having the use of one arm can use his rifle almost with as much facility as with both, either in the stooping or kneeling position; a fact I submit of no small importance to the wounded soldier—in protecting himself, for instance, from marauders, who, however unscrupulous in general in silencing resistance, would not face a loaded rifle.

5thly. The expense of fitting the rest to the present Enfields, or any other rifle, would be very trifling, and if broken or impaired it is easily replaced, without injury to the rifle.

I repeat that I by no means wish to make it compulsory that every man *must* use a rest; still I feel quite sure that there are many men who would at all times fire better with it; and for taking a deliberate aim, and at long distances, I cannot but think that nearly all would find it a simple and useful appendage to the rifle.

W. Connolly, *Captain, R.N.*

Bury-road, Gosport, April 20th, 1859.

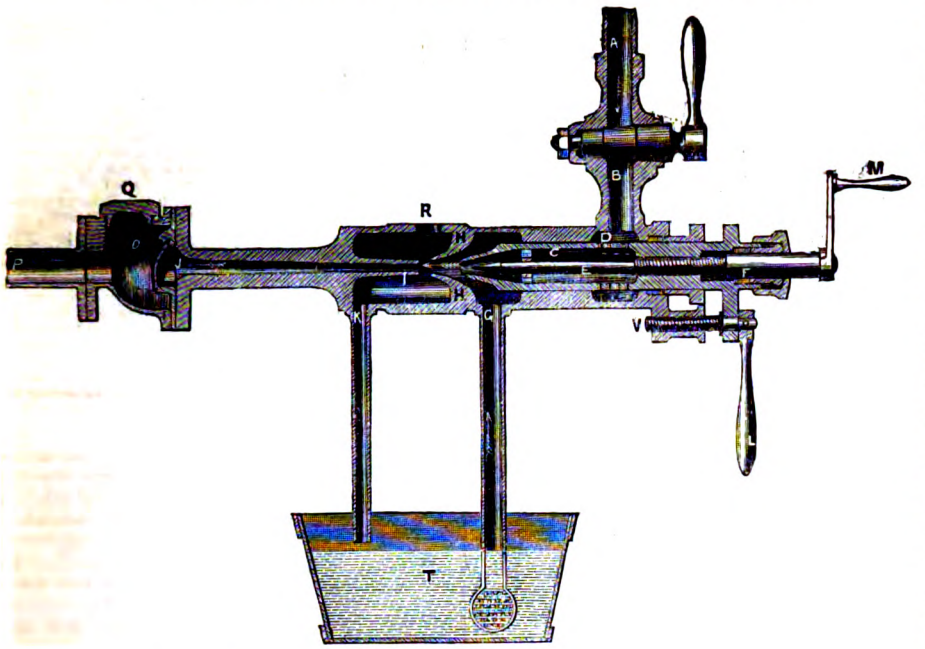
SUBSTITUTE FOR FEED PUMPS AND DONKEY ENGINES.



A VERY curious apparatus, called an *Automatic Injector*, invented by M. H. Giffard, and made by M. H. Flaud, the well-known engineer of Paris, has recently attracted considerable attention amongst scientific and practical men in France. The apparatus has been adopted by the Director General of Naval Construction in France; and has already been ordered by more than one well-known firm in the north of England.

The object of the apparatus is to supply water to the boilers of steam engines, or other steam apparatus, by means of the force of the steam contained in the boiler alone, and to return to the boiler all, or very nearly all of the heat contained originally in the steam thus used as the motor for supplying water to the boiler. It works without any aid from machinery; it is, in fact, perfectly automatic, as the title implies, and, consequently, it acts equally well when the steam-boat, locomotive, or engine to which it is attached, is in motion, or at rest.

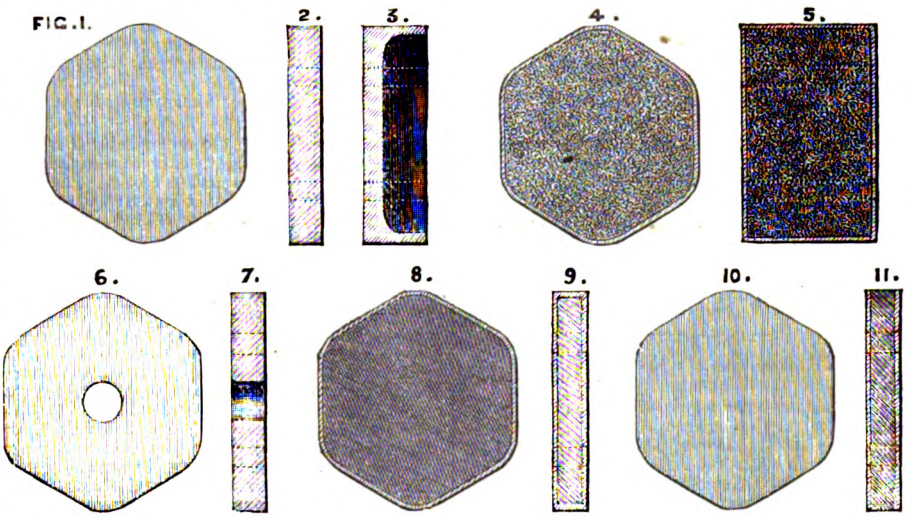
A B is the pipe bringing steam from the boiler; *C D* another pipe or chamber which receives the steam from the former through the holes at *D*—this latter pipe terminates conically; *E F*, small piston or rod working by means of a screw and handle, *F M*; this serves to regulate or prevent entirely the passage of the steam; *G* is a suction water-pipe. The water is drawn up into the chamber which surrounds the conical end of the steam pipe *C D*, and passes through the opening marked by an arrow between *H H*. The space left for the exit of the water is regulated by means of the lever and screw *L*, which moves the steam pipe, or chamber, *C D*, in either direction; *I J*, is a passage to carry the water to the boiler, together with the steam which communicates to the water a portion of the force with which it is charged by the pressure in the boiler; *O* is a valve to prevent the return of the water from the boiler when the apparatus is out of work; *P* leads directly to the boiler; *Q*, is a screw stopper, to allow of readjustment or cleansing of the valve; *K* is a tube which carries off any superabundant water which may collect in the space around; *I R* is an opening with a sliding corner, through which the action of the apparatus may be distinctly seen; the steam and water combined forming a continual and rapid stream between the parts *H* and *I*.

To work the apparatus—the diameter of the water supply pipe being calculated to give the necessary amount of water—the rod *E F* is moved forward by the handle *M*, until the conical end of the rod stops the orifice of the cone. The steam cock in the pipe *A B* is then turned on; the screw handle *M* is then turned back a turn or so, to permit a small quantity of steam to pass. The steam in its rapid passage creates a vacuum in the chambers of the apparatus, and the water rushes up the pipe *G* into the space above. As soon as the water has entered, the handle is turned round so as to draw back the conical rod, and permit free passage to the steam; the water is then carried rapidly into the boiler, and ceases to run off by the discharge pipe *K*.

The principle upon which the apparatus is based is, that as the pressure is equal upon all the interior surface of a steam boiler, and consequently as each unit of surface sustains the same pressure, if the steam is taken from the boiler into the apparatus by a larger orifice than that through which it is returned, the force of entry of the steam will be greater in proportion to the dimensions of the two orifices; or, in other words, steam brought from a boiler through a pipe of a given diameter, can easily be forced into the boiler again through the other end of the pipe, provided it have a much smaller aperture. In the machine in question the entering orifice bears but a very small proportion to that of the supply pipe, because it is necessary to allow for the loss of force occasioned by the action of the water upon the steam.

In the above cut the apparatus is represented in a horizontal disposition, whereas it is now made vertical, but the only difference in the arrangement of the parts is the curving downwards of the two water-pipes *G* and *K*.

WHITWORTH'S IMPROVEMENTS IN GUNS, GUN-CARRIAGES, AND AMMUNITION.



MR. JOSEPH WHITWORTH has just completed a patent for a set of improvements, which relate first, to a mode of giving accurate horizontal adjustment to a gun by moving its trunnions laterally in their bearings. This is effected by means of a lever which acts on one of the trunnions, the opposite end of the lever being connected with a screw which is adjusted by hand. To this apparatus, and mode of adjusting guns, the patentee makes no claim. Secondly, it relates to the use of discs or cakes of wax, tallow, or other similar lubricating compounds or substances, as wads for ammunition for ordnance and fire-arms, whereby the piece is properly lubricated. The lubricating materials may consist of bees-wax and tallow, used separately or combined, or of paraffine, or of such other similar substances as are not materially affected by being exposed to the action of the atmosphere. Mr. Whitworth has obtained good results from a composition consisting of equal quantities of wax and tallow; but the proportions may be varied according to the temperature of the weather and climate, care being taken that a sufficient quantity of tallow is used to ensure perfect lubrication of the barrel at low temperatures, while sufficient wax is employed to make the wad cohere, and withstand the effect of high temperature. Instead of mixing the wax and tallow together whilst both are in a melted state, he sometimes melts the wax, and runs it into a mould and when set pours the tallow on to the wax. In this case the tallow adheres to, but does not mix with, the wax, which thus forms a coating. In making wads for small arms, he takes a cake or sheet of the lubricating material made of the requisite thickness, and by means of a suitable punch cuts out of it wads or discs. Or the melted material may run in the form of a rod, and afterwards be cut into wads or discs. In making wads for large ordnance, he prefers to use moulds of the proper size and shape corresponding with the interior of the piece. The material is poured into the moulds, and allowed to set. Other modes of manufacturing, forming, moulding, or cutting the discs or wads may be adopted, but the simple methods explained answer well. Mr. Whitworth uses one or two discs or wads similar to those shown in end view in Fig. 1, and in section in Figs. 2 or 3. When two discs or wads are used, they may be of diminished thickness, one being

Digitized by Google

placed in front of, and the other behind the powder. He also in some cases connects the two discs together by a casing of thin wax, as shown in Figs. 4 and 5. The space between the two discs forms a chamber in which the powder may be inserted, as in a bag or cartridge, and where necessary, he uses several such chambers, which are made short for the sake of strength. Perforations must be made to secure communication and complete ignition of the powder in the several chambers. He also uses perforated wads, as in Figs. 6 and 7, made of lubricating material, which he places in the midst of the powder to remove the deposits caused by excessive fouling when inferior powder is employed. In some cases he employs roads made with the softer lubricating material in the centre, surrounded by a casing of harder substances, such as wax, or other suitable material, as shown in Figs. 8 and 9; or the wad may be made of wax on the front and rear sides, and tallow between, as shown in Figs. 10 and 11—all of which several descriptions of wads are applicable to small arms and ordnance. In all cases the lubricating materials, or compounds, which he employs as described, consist wholly of substances that are melted by the heat of, and are altogether dispersed by, the exploding gases of the powder; the use of pulpy or fibrous materials may be altogether dispensed with. In choosing the lubricating materials, or compounds that may be required for use in hot climates, it will be necessary to select such as are to a certain extent heat-resisting, and possess the necessary hardness and toughness. He prefers to employ these in combination with other substances easily melted, as shown in Figs. 8, 9. 10 and 11.

Thirdly, the invention relates to the application of tin or zinc, or other hard metals or alloys, as an outer coating for soft metal rifle projectiles. The soft metal for the projectiles is made in a continuous length, and is coated by an adaptation of the well-known apparatus employed in manufacturing lead pipes, and coating them with tin, or other metal, and which it is not necessary to describe. Any apparatus whereby the soft metal is made in a continuous length, suitable for being divided into shorter pieces, and formed into projectiles by the ordinary bullet-making machinery, may be used, provided the continuing length of metal is forced through suitable dies, and through a bath of melted coating metal, or alloy, whereby a continuous coating is deposited.

ROYAL NAVAL ENGINEERS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The very kindly manner in which you have taken up the case of the Royal Naval Engineers, in your Magazine of March 4th, induces me to trouble you with a few remarks in reference to the position in which the Admiralty think fit to keep this important class of officers. The Naval service is in many respects remarkable for its anomalies, but that of the status of its engineers is certainly one of the most curious, their position being of the most undefined and indistinct character. They are supposed to be placed upon the same footing as Masters, yet we find a great many differences, both as regards treatment and emoluments. The "with but after" rank applies also to other officers, but in the case of engineers it is a veritable fact, for from the treatment accorded them they are made to feel that they rank "*after*" everybody. As you justly observe, if "there is any inferiority in the character and education of the engineers, the fault lies with the Admiralty who admit such persons." And how does this system, or rather want of system, act? The engineer, looked down upon, and in many cases brow-beaten by his superior officers (?), finds his engine-room occasionally converted into a blacksmith's or carpenter's shop, for ship's work, utterly regardless of his remonstrances and representations, that his machinery will suffer not only by the possibility of accident but also by the positive neglect compulsorily entailed by such a course: or perhaps he finds his prospects, and his character and reputation as an engineer, ruined in consequence of the inefficiency of his machinery, when that result has actually been brought about by the arbitrary conduct of the captain, who, in order to have a "*smart ship*," takes his stokers to pull ropes, to work guns and polish brass-work, when they ought to be employed in the engine-room in keeping the machinery in order. These are and must be the results of a system which gives the engineer no position in the ship, and no voice in the appropriation and employment of his men, except when positively under steam. It may be said that the efficiency of the engine-room ought to be the first wish of a sensible commander; granted, and there are fortunately many who have a just appreciation of the importance of the duties of the engineer; but for one such, how many are there who entertain a thorough contempt for what they please to call a "mere mechanic," who laugh at, and "pooh-pooh" his representations, and treat his objections as "paltry obstacles," knowing full well that when the natural result does take place it will be but a few weeks in harbour under repairs; and should the engineer be reprimanded or reduced it is of not the slightest concern. Such cases do occur, and will continue to do so, until the engineer obtains proper consideration, and until his position is properly defined, and he is given a thorough and undivided control over his own department—men as well as machinery. The French Emperor saw the necessity of placing the engineers of his navy on a proper footing. Class prejudice had no place in his mind when reconstructing the Naval power of France, and it is to be hoped that Sir John Pakington will be sufficiently wise to include in his reforms a proper organisation of this important, and now absolutely necessary body of officers. Unfortunately for Naval engineers, the journals, with the exception of your own, which are especially devoted to engineering and scientific information, hold aloof from this question, and instead of affording what would be felt as great and important aid, look coolly on at the struggles of their naval brethren, and in too many cases, it is to be feared, consider it a matter of satisfaction than otherwise, that their exertions are so fruitless and their progress so small. Under such circumstances, engineers will be doubly grateful for the just and considerate articles in your journal. I shall be very glad, if you will afford me space at another time, to go further into this matter in order to expose one or two other anomalies, especially in reference to the treatment of the junior branches of the profession, but I am afraid that I have already trespassed too far upon your space.

I am, Gentlemen, yours truly,

CRANK.

[We avail ourselves of the opportunity which the preceding letter affords, to offer a remark for the guidance of engineers and others in the Royal Navy. We have found that in the minds of some there exists a crude belief, or at least a dread, that we are in some way associated with, and in the confidence of, the British Admiralty, or some of its high officers. This has been conjectured, we are informed, in consequence of some of the information which we have on former occasions published having an official appearance. The consequence is, some of the Naval engineers have felt doubtful whether it was quite a safe thing to commit their confidence to us. We desire to assure any such that their fears are utterly groundless. Let them only turn over our pages since January last, and they will find that when we have had occasion we have spoken without hesitation or scruple against, as well as for, the Admiralty and all its officers. We are not in the personal or private confidence of any Government functionary whatever, and therefore in no sense is our independence compromised. The true and only secret of whatever interest we may possess in reference to the navy is to be found in the fact that we write upon what we understand, and that we do not write upon what we are ignorant of—as mere journalists unhappily do.—EDS. M. M.]

MR. BESSEMER'S IRON-MAKING PROCESS.

April 11, 1859.

GENTLEMEN,—Upon the communication having been made to the Society of Civil Engineers of Paris relative to a new method of obtaining metals in a finely-divided state by means of rotation, the President—it is stated in your last week's impression—objected to the process because "the rotating action of the foreign bodies contained in the iron could only be effected at the cost of the combustion of a portion of the iron itself, as occurred in casting, and *also happened in Mr. Bessemer's apparatus.*" Now there is little doubt but the said president is a man of integrity and high scientific attainments; any statement, therefore, emanating from such a source, would necessarily carry with it a certain amount of weight, and tend to influence the public mind. It is to be regretted, therefore, that an error of this kind should have obtained credence with such a man. It is satisfactory, however, to know, that notwithstanding the prejudice and misrepresentation to which the Bessemer discovery has been subjected, it is steadily and surely establishing for itself a reputation as lasting as steel itself, and which shall carry down to generations yet unborn the name of its author as one of the greatest inventors of his age. That the discovery had difficulties to contend with, obstacles to surmount, details to work out, none could deny. Nor did any person at all conversant with such matters doubt, even at its birth, that such would be the case. Some there were, indeed, who were so dazzled by the brilliancy of the idea as to be unable, or unwilling to see such difficulties, and who, therefore, in their *impatience*, scoffed at that which before had given them so much delight, but for the fruits of which they could not wait. Others of a more practical turn of mind having witnessed the dawn of the discovery, were content to abide with patience its complete development. Nor have such been disappointed in their expectations. For a considerable time the invention has been in successful operation in a foreign land, and now works are established in our own country from which steel of the very best description is being daily turned out in large quantities, not only yielding large profits to the principals, but affording comparative sinecures to the operatives employed thereon. Such, indeed, is the reputation which the Bessemer steel has established for itself, that none is permitted to pass from the works without the mark of the firm; and so well satisfied with it are many of the principal engineering firms, that they now use nothing else; this, too, after the use, in many cases, of several tons upon their own tools alone. Some of the principal railway works, too, are also extensive users of this steel, and give to it the preference over all other kinds. Nor are these results the effect of any adventitious circumstances, as might have been said to be the case when the matter was first taken up by the public press, but are attributable solely to the intrinsic excellence of the metal itself. The inventor being fortunately a gentleman of adequate means and high mechanical genius, has done that which too many inventors could not have done; that is, he has not only established works on a sufficiently large scale to develope his discovery practically and profitably, but he has introduced therein a number of mechanical contrivances of such beauty and completeness, that workmen of the most ordinary capacity of mind can scarcely fail of working the new principle efficiently. Hence we do not presume to much prescience when we predict that the time is not distant when this discovery shall be employed generally throughout the world. Indeed it cannot well be otherwise; for apart from the prejudice and obstacles which are so generally opposed to all new ideas, which are likely to interfere with existing plants, it will manifestly be to the pecuniary advantage of manufacturers to adopt it. From trials recently made upon the Bessemer iron and steel at Woolwich, and elsewhere, the following are the mean strengths:—

Iron boiler plate...	68.347
Bar iron	75.897
Round steel	162.970

When we consider, therefore, that the ordinary strength of Staffordshire bar iron is only 56.000, the superiority of this over other kinds of iron will at once be apparent. Moreover, such is the toughness of the boiler plates that pieces ¾ thick can be folded up, while cold, like a sheet of paper, and though doubled over three or four times, and flattened down, they show no symptoms of fracture at the edges of such folds. Such, too, is the strength and toughness of the steel, that a spiral shaving about seventy feet in length, was a short time since submitted to Mr. Bessemer by one of the workmen. This shaving, a portion of which the writer has seen, more resembles a piece of wire rope than anything else. With such evident advantages, therefore, as this process possesses over all others, and with the facilities which it affords the inventor of making cylinders, cannon, &c., *in the converting* operation, it is impossible to foretell the ultimate benefits which will accrue therefrom. I am, Gentlemen, yours truly,

WILLIAM GREEN.

Victoria Works, Dod-street, Limehouse.

April 24th, 1859.

P.S.—If *one* great advantage has come from the experiment in gun founding at Woolwich, a still *greater advantage* to the public has generally resulted from M. Bessemer's discovery in connection with the same object. A gun has recently been made by the Bessemer process from Hæmatite iron, which is quite a marvel in metallurgy. A six-inch round ingot having been run, it was then heated and rolled in the usual manner, until reduced to the proper dimensions for a four-inch gun. After being turned and bored, a cylinder of about six inches in length was cut therefrom, and subjected to hydraulic pressure until completely flattened. Yet notwithstanding this severe test no symptom of a crack or fracture could be discovered upon any part thereof. Now, certainly no metal at present in use for ordnance—not even the best gun-metal—would stand such a test, and yet the price of the prepared ingots at Woolwich, after paying good wages to skilled workmen and the several expenses connected with rolling, &c., would not exceed the price of the commonest pig iron now used for cast-iron ordnance. Rejoicing as I do, therefore, to see scientific merit rewarded—sparingly, alas, as it is—I trust that an invention of such transcendent beauty and national importance will soon be adopted by the Government authorities, and that its indefatigable author will receive that honour and reward to which he is justly entitled.

THE HOUNSLOW EXPLOSION.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—The inquiry into the accident at the Hounslow Gunpowder Works has been again postponed, and this time for a month. It is not, I presume, your purpose to make any comment upon the proceedings of the inquest until the report of those deputed to examine scientifically into the causes of the event are before the public. Then with

Digitized by Google

your permission I may have a good deal to say respecting the discrepancies which arose during the inquiry, and some explanations to offer which may reconcile many of them and account for the inconsistencies of others. One remark will not, however, be here out of place. Surely the council employed by the manufacturers were not, even by their zeal for their clients, justified in stating that the scene of the disaster was at the period of the inquest exactly in the same state as it was at the immediate moment after the explosion, nor could the managers of those works have instructed their advocates to state that such was the case. *For such was not the truth.* It may be that nothing had been touched that was deemed of importance by those in authority, "but things to a very great extent had been made straight," and the supernumerary gang of masons and bricklayers' labourers could scarcely have dared to remove a fallen tree or a barrow of bricks from the spot unless they had been so instructed. Indeed, they would have found enough to do in repairing the brick-work and re-tiling the surrounding buildings on the premises, before they essayed to mitigate the horrors of a scene which was quite bad enough after being thus "put to rights." What I mean to imply is not blame to any one, but what you, gentlemen, should insist upon is, that not a stock nor a stone ought to have been turned much less moved from the spot in which it fell. In case of a fire the premises of which are insured, the whole place, as it lies, is taken possesion of by trusworthy men deputed to this office. In the event of an accident of this nature the coroner ought to be held in some wise responsible for "the situation," and it ought not to be left to an irresposible and paid advocate, to impart the necessary amount of confidence into the inquiry, to insure strict and impartial justice to be done, and a rational conclusion of causes if possible being arrived at. You have very justly the ear of the public in such and similar cases as these. The ordinary journalist dare not approach it for lack of the more intimate knowledge of the subject, and the less conscientious but not the less gifted of "the chemically practical" have a decided "shop interest" in such events. I pray you, therefore, do not wait until the neighbourhood is again aroused to force the proper and most diligent inquiry by the pressure you can bring to bear upon it.—I beg to remain, yours, &c., A. Z.

SUBMARINE TELEGRAPHS.

Gentlemen,—In your journal of the 15th inst. I observed a statement, headed "A Novel Method of Telegraphing," and due to Messrs. Hoga, Piggott, and Beardmore. I am not aware of the date of those gentlemen's claim for the invention as therein stated, but beg to state that provisional protection for an invention of a similar nature was applied for and granted to me in the month of October last. I also observe that those gentlemen abandoned their provisional protection for the invention. In my own case, however, my investigations, extending over a period of many months, have been of a nature sufficiently satisfactory to induce me to an opposite course; and my final specification for the same was completed on the 16th day of the present month. B. Nickels.

Mitcham, 23rd April, 1859.

The *Photographic News* announces a very singular discovery, by M. L. Scott, by means of which sounds may be made to record themselves, whether they are those of musical instruments, or emitted by the voice in singing or speaking. Professor Wheatstone, during his recent visit to Paris, was invited by the Abbe Moigno to inspect the papers on which these sounds had printed themselves, and is said to have been greatly surprised and pleased with what he saw. The mark produced on the paper by a particular note is invariably the same; so, also, if a person speaks, the tone of voice in which he speaks is faithfully recorded. As yet no practical advantage has been obtained by this discovery; but M. Scott is sanguine that, in course of time, he will so far improve his apparatus that it will be capable of printing a speech, which may be written off *verbatim*, to the great saving of the labour of Parliamentary reporters.

THE NEW PATENT LAW OF INDIA.

The following is an authentic copy of the new Patent Law of India, derived from the official paper of the Commissioners of Patents for Great Britain:—

Whereas it is expedient, for the encouragement of inventors of new manufactures, that certain exclusive privileges in their inventions should be granted to them in India, and that such exclusive privileges should be protected:—It is enacted as follows (the sanction of Her Majesty to the passing of this Act having been previously obtained and signified in pursuance of the statute):—

I. The inventor of any new manufacture may petition the Governor General of India in Council for leave to file a specification thereof. Every such petition shall be in writing in the form or to the effect mentioned in the schedule hereunto annexed, and shall be signed by the petitioner or (in case the petitioner shall be absent from India), by an authorised agent, and shall state the name, addition and place of residence of the petitioner, and the nature of the invention.

II. Upon such petition the Governor General of India in Council may make an order authorising the petitioner to file a specification of the invention.

III. Before making such order the Governor General of India in Council may refer the petition to any person or persons for enquiry and report, and such person or persons shall be entitled to a reasonable fee for such enquiry and report, to be paid by the petitioner, the amount of such fee, in case of dispute, to be settled by a judge of one of Her Majesty's Courts of Judicature in a summary manner.

IV. If, within the space of six calendar months from the date of such order the petitioner cause a specification of his invention to be filed in manner hereinafter mentioned, the petitioner, his executors, administrators, or assigns, shall be entitled to the sole and exclusive privilege of making, selling, and using the said invention in India, and of authorising others so to do, for the term of fourteen years from the time of filing such specification, and for such further term (if any) not exceeding fourteen years from the expiration of the first fourteen years, as the Governor General of India in Council may think fit to direct, upon petition to be presented by such inventor at any period not more than one year, and not less than six calendar months, before the expiration of the exclusive privilege hereby granted.

V. An order authorising the filing of a specification, or for extending the term of such exclusive privilege as aforesaid, may be made subject to any such conditions and restrictions as the Governor General of India in Council may think expedient.

VI. Every specification of an invention filed under this Act shall be in writing, and shall be signed by the petitioner, and shall particularly describe and ascertain the nature of the said invention, and in what manner the same is to be performed.

VII. Every petition for leave to file a specification and every specification filed under this Act shall be left with the Secretary to the Government of India in the Home Department, and every petition and specification shall be accompanied by a declaration in writing, signed by the petitioner in the form or to the effect mentioned in the schedule hereunto annexed, marked A and B respectively; and if the inventor be absent from India, the petition and specification shall also be accompanied by a declaration signed by the agent who shall present or file the same, to the effect that he verily believes that the declaration, purporting to be the declaration of the inventor, was signed by him, and that the contents thereof are true, which declaration shall be in the form, or to the effect mentioned in the said Schedule. The date of the delivery of every such petition and specification shall be endorsed on the same respectively, and shall also be recorded at the office of the said secretary.

VIII. If any person who shall make a declaration under this act shall wilfully and corruptly make any false statement therein, he shall be deemed guilty of perjury, and shall be proceeded against, and upon conviction punished accordingly.

IX. No specification shall be filed until the petitioner shall have paid all fees payable under this Act, including the fees (if any) of the person or persons to whom the petition shall have been referred for enquiry and report.

X. At the time of delivering the specification for the purpose of being filed, the petitioner shall cause to be delivered to the said secretary five copies thereof, of which,—

One shall be sent to and filed by one of the Secretaries to the Government of Bengal;

One shall be sent to and filed by one of the Secretaries to the Government of Fort St. George;

One shall be sent to and filed by one of the Secretaries to the Government of Bombay; and

One shall be sent to and filed by one of the Secretaries to the Government of the North-Western Provinces.

A copy of such specification shall be open at all reasonable times at the Office of each of the said Secretaries to public inspection upon payment of a fee of one rupee.

XI. A book shall be kept in the office of the said secretary to the Government of India, wherein shall be entered and recorded every such petition and specification, and every order made upon such petition or relating to the invention therein mentioned. Every specification shall be numbered according to the order in which it is entered in such book; and a reference shall be made in such book, in the margin of the entry of each specification, to every order relating to the invention, and to every petition, memorandum, or amended specification, which shall be filed under the provisions of Section 14.

XII. Such book, or a copy thereof, shall be open at all convenient times for the inspection of any person upon payment of a fee of one rupee; and the said secretary shall cause a copy of any entry therein, certified under his hand, to be given to any person requiring the same on payment of the expense of copying.

XIII. Every such certified copy shall be *prima facia* evidence of the document of which it purports to be a copy.

XIV. If after the filing of the specification the petitioner shall have reason to believe that through mistake or inadvertence he has erroneously made any misstatement in his petition or specification, or included therein something which at the date of his petition was not new, or whereof he was not the inventor, or that such specification is in any particular defective or insufficient, he may petition the Governor General in Council for leave to file a memorandum, pointing out such error, defect, or insufficiency, and disclaiming any part of the alleged invention, or in case of any defect or insufficiency of the specification for leave to file an amended specification. The petition shall state how the error, defect or insufficiency occurred, and that it was not fraudulently intended, and shall be accompanied by a declaration in writing signed by the petitioner, and if he be absent from India by his agent, stating that the contents of such petition are true, to the best of his knowledge and belief. Upon such petition the Governor General in Council may make an order allowing such memorandum or amended specification to be filed. All the provisions of sections X., XI., XII., and XIII., applicable to the specifications, shall be applicable to the petitions, orders, and memoranda or amended specifications referred to in this section. An amended specification filed under the provisions of this Act shall, except as to suits or proceedings relating to the exclusive privilege which shall be pending at the time of the filing of such amended specification, have the same effect as if it had been the specification first filed; provided that nothing contained in an amended specification shall extend or enlarge any exclusive privilege before acquired.

XV. No person shall be entitled to any exclusive privilege under the provisions of this Act—

If the invention is of no utility; or

If the invention, at the time of presenting the petition for leave to file the specification, was not a new invention, or within the meaning of this Act; or

If the petitioner is not the inventor thereof; or

If the specification filed or the amended specification (if any) does not particularly describe and ascertain the nature of the invention, and in what manner the same is to be performed; or

If the original or any subsequent petition relating to the invention, or the original, or any amended specification, contain a wilful or fraudulent misstatement.

XVI. Every exclusive privilege under this Act shall cease if the Governor General of India in Council shall declare that the same, or the mode in which it is exercised, is mischievous to the State, or generally prejudicial to the public; or if a breach of any special condition on which the petitioner shall be authorised to file a specification, or upon which the term of the exclusive privilege shall be extended, shall be proved to the satisfaction of any of Her Majesty's Courts of Judicature, and if the Governor General of India in Council shall thereupon declare that such exclusive privilege shall cease.

XVII. The importer into India of a new invention shall not be deemed an inventor within the meaning of this Act unless he be the actual inventor.

XVIII. A foreigner, whether resident abroad or not, may petition for leave to file a specification under this Act.

Digitized by Google

XIX. An invention shall be deemed a new invention within the meaning of this Act if it shall not, before the time of applying for leave to file the specification, have been publicly used in India, or in any part of the United Kingdom of Great Britain and Ireland, or been made publicly known in any part of India or of the United Kingdom by means of a publication, either printed or written, or partly printed and partly written. The public use or knowledge of an invention, prior to the application for leave to file a specification, shall not be deemed a public use or knowledge within the meaning of this section, if the knowledge shall have been obtained surreptitiously or in fraud of the inventor, or shall have been communicated to the public in fraud of the inventor or in breach of confidence: provided the inventor shall, within six calender months after the commencement of such public use, apply for leave to file his specification, and shall not previously have acquiesced in such public use: provided also, that the use of an invention in public by the inventor thereof, or by his servants or agents, or by any other person by his licence in writing, for a period not exceeding one year prior to the date of his petition, shall not be deemed a public use thereof within the meaning of this Act.

XX. If an inventor who, prior to the time of applying for leave to file a specification of an invention under this Act, shall have obtained Her Majesty's Letters Patent for the exclusive use of such invention in the United Kingdom, or any part thereof, shall, within twelve calendar months from the passing of this Act, or within twelve calendar months from the date of such Letters Patent, petition the Governor General of India in Council for leave to file a specification of such invention (which petition shall be in writing, in the form or to the effect mentioned in the schedule), the invention shall be deemed a new invention within the meaning of this Act, if it was not publicly known or used in India at or before the date of the petition for such Letters Patent, notwithstanding it may have been publicly known or used in some part of the United Kingdom or in India before the time of his petitioning, under this Act, for leave to file the specification: provided the petition for leave to file the specification shall state that such Letters Patent have been granted, and shall also state the date thereof and the term during which the same are to continue in force: provided also, that an exclusive privilege obtained under the provisions of this Act by an inventor who has obtained Her Majesty's Letters Patent for the exclusive use of such invention, shall cease to have effect if such Letters Patent be revoked or cancelled; and that no such exclusive privilege shall extend beyond the term granted by such Letters Patent unless the same shall be renewed, in which case the exclusive privilege may be renewed under this Act for the extended term or any part thereof.

XXI. No exclusive privilege obtained under this Act shall entitle the owner of such privilege to exclude any person from using the invention, who, prior to the 7th day of July, 1855, used the same in India.

XXII. An action may be maintained by an inventor against any person who, during the continuance of any exclusive privilege granted by this Act, shall, without the licence of the said inventor, make, use, sell, or put in practice the said invention, or who shall counterfeit or imitate the same: provided that no such action shall be maintained in any court other than the principal court of original jurisdiction in civil cases within the local limits of whose jurisdiction the cause of action shall accrue or the defendant shall reside as a fixed inhabitant.

XXIII. No such action shall be defended upon the ground of any defect or insufficiency of the specification of the invention, nor upon the ground that the original or any subsequent petition relating to the invention, or the original or any amended specification, contains a wilful or fraudulent mis-statement; nor upon the ground that the invention is not useful; nor shall any such action be defended upon the ground that the plantiff was not the inventor, unless the defendant shall show that he is the actual inventor, or has obtained a right from him to use the invention either wholly or in part. Any such action may be defended upon the ground that the invention was not new, if the person making the defence, or some person through whom he claims, shall, before the date of the petition for leave to file the specification, have publicly or actually used, in India or in some part of the United Kingdom, the invention, or that part of it of which the infringement shall be proved, but not otherwise.

(To be concluded in our next.)

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and or 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Our Weekly Gossip.

We stated last week that fifteen people had been saved by the use of Clifford's boat-lowering gear; it is now our painful duty to record the loss of three lives through the want of it. Her Majesty's new steam frigate Doris was on Thursday last trying her speed at Spithead when she ran into a smack and sank her, the two men and the boy in her at the time leaping out to save themselves from a worse fate. The boats hung in the old falls and tackles, and it was nearly ten minutes before one of them could be lowered. The two men were lost, and the boy taken on board in such an exhausted condition that he died almost directly. This occurred in broad daylight, in almost smooth water, with plenty of men to man the falls efficiently, and everything, on such an occasion we may be sure, in good trim. In the case we gave last week, when the people were saved, the collision took place at night, and in *ten minutes* after the first shock not a vestige of the ship from which the rescued persons were taken was to be seen, and yet all were saved. In one case an efficient means of lowering the boats instantly was at hand, in the other there was none. We but a few weeks since alluded to the disregard of life shown by the Admiralty for the seamen, and it gives us no little pain to have now to give so prominent an instance in support of what we then advanced.

On Thursday night some experiments took place at Devonport, in the presence of Port-Admiral Sir Barrington Reynolds, and a large party, for testing the use of "Robson's Patent Signal Lights," in conjunction with Redl's Code, an article on which appeared in the last number of this Magazine. These lights are of various colours, and may be made to burn with the most intense brilliancy for from three minutes to half-an-hour. The trial gave great satisfaction, and it was the unanimous opinion of the authorities present that these lights are invaluable in conjunction with the Redl signals. Communication was quickly obtained from the flag-ship Impregnable, lying off Mount Edgcombe, and the gunnery-ship Cambridge, in Hamoaze. Mr. Robson also exhibited some of his new rockets, made expressly for signalizing. These rockets throw out a brilliant ball of coloured fire, which floats in the air some time after the discharge. Mr. Robson's lights have been repeatedly brought to the notice of the Admiralty, and reported upon most favourably by their officers. We presume measures will now be taken to secure them for the use of the Royal Navy.

We have before us a report of a select committee of the American Institute of the city of New York, appointed "to examine the paying-out machinery on board of the United States steam frigate Niagara, and to furnish a report thereon concerning the design and construction thereof." The committee have arrived at the following conclusions:—1st. That the apparatus used in the first attempt to lay the Atlantic telegraph cable, composed of the paying-out instrument of four geared sheaves, and the brake used, failed, and that the use of them was wholly abandoned in the second attempt. 2nd. That although Appold's brake was attached to the apparatus used in the second essay, and made an integral and essential portion of it, yet it was very materially modified before it could be adapted to the peculiar purpose for which it was resorted to. 3rd. That the paying-out instrument by which this cable was laid, had but two sheaves, running independent of each other, and that in this essential feature it was wholly novel. 4th. That this instrument and the modification of Appold's brake was constructed from the designs of and under the direction of chief engineer Wm. E. Everett, U. S. N. 5th. That the entire apparatus was constructed by the authority of the Directors of the Atlantic Telegraph Company, and that its design and construction was confided to Mr. Everett alone. Finally, That if the apparatus had proved inadequate to the required purpose, that Mr. Everett could alone have been held professionally responsible, as the paying-out instrument of his design was essentially different from that recommended by the commission of engineers. In conclusion, the committee add that although without proper paying-out machinery in the vessels of transportation, it would not have been practicable to lay the cable, yet that the mere possession of such machinery did not constitute all that was requisite to attain this end, as the proper stowage of the cable and the manner of its delivery to the paying-out machine was equally necessary to success. The important duty of superintending both the stowing and the delivery on board of the Niagara and Agamemnon was delegated to Messrs. W. H. Woodhouse and Samuel Canning, civil engineers of London, to whose skill, ingenuity, and unremitting attention is to be ascribed in a large degree the successful issue of the laying of the Atlantic telegraph cable. Signed by "Chas. H. Haswell, Horatio Allen, Geo. W. Quintard, John A. Bunting, Joseph P. Pirsson, Chas. W. Copeland," and dated New York, March 3rd, 1859.

From a paper issued by the Crystal Palace Company we learn that the ensuing season at the Palace promises to be one of the most brilliant and important which it has ever had. It will be the year of the "Great Handel Festival," for which so many great preparations have been long making. But the Directors do not allow the great event to influence their efforts for, or to decrease the other attractions. It will be found that all the usual "events" are to come as usual. There will be four Flower Shows: the first—always one of the most brilliant ever seen, and on account of the season doubly charming—on May 18th. The second on June 8th, when the flowers are in their fullest luxuriance. The third, on September 7th, and following days, will be the show at which the Dahlias, Hollyhocks, and the beautiful autumn flowers are shown: and the fourth on Nov. 9th, for Crysanthemum Shows. There will be also a series of Six Opera Concerts by the Covent-garden artistes, and many other concerts beside. The programme contains a long enumeration of the permanent features of the Palace, which are equally interesting, and allusions are made to the great gatherings and fetes which always take place, apart from the fixed arrangements of the Company itself, such as the Early Closing Association Fetes, the gatherings of the Foresters, &c., which are features of themselves. The season opens formally on Monday next, with a Fete in commemoration of the Indian Rebellion, which will be important in many respects. In the neighbourhood of the Palace, even at this early period, we are told there is scarcely a house to let, or a lodging or hotel accommodation which has not been taken up, even at very high prices; during the times of the Handel Festival the throng of visitors in the neighbourhood will doubtless be very great. The Season Tickets will be of two classes; one at *two guineas*, which will admit to everything during the season, except to the performances of the Handel Festival; and one at *one guinea*, which will admit to everything (with the same exception) when the price of admission is under five shillings.

One of the last Acts passed in the late session was to amend and explain the statute 6th George IV., cap. 129, to repeal the laws relating to the combination of workmen, and to make other provisions in lieu thereof. It seems that different decisions have been given on the construction of the recited Act, and it is now enacted that no workman or other person, whether actually in employment or not, shall, by reason merely of his entering into an agreement with any workman or workmen, or other persons, for the purpose of fixing, or endeavouring to fix, the rate of wages or remuneration at which they, or any of them, shall work, or by reason merely of his endeavouring peaceably, and in a reasonable manner, and without threat or intimidation, direct or indirect, to persuade others to cease or abstain from work, in order to obtain the rate of wages or the altered hours of labour so paid or agreed upon, or to be agreed upon, shall be deemed or taken to be guilty of "molesta-

Digitized by Google

tion" or "obstruction" within the meaning of the Act, and shall not therefore be subject or liable to any prosecution or indictment for conspiracy. There is a proviso to the clause that nothing contained shall authorise any workman to break or depart from any contract or authorise any attempt to induce any workman to break or depart from any contract he may have entered into.

A recent number of the *Revue des Deux Mondes* contains an interesting article on the Naval Arsenal at Cherbourg, says the *Athenæum*, from which it appears that the works have cost £7,611,000. They are thus divided:—

PERIODS.	Sea Works.	Fortifications and War Buildings.	TOTAL.
	Francs.	Francs.	Francs.
Ancient Monarchy, from 1783 to 1792	31,192,679	10,243,268	41,436,047
Republic, from 1793 to 1800	.....	.....	.....
Consulate and the Empire, from 1801 to 31st March, 1814	29,466,387	8,971,296	38,377,683
Restoration, from 1st April, 1814, to 31st July, 1830	10,336,115	1,587,494	11,923,609
Government of July, from 1st August, 1830, to 24th February, 1848	40,656,139	8,467,556	49,123,695
Republic, 25th February, 1848, to 2nd December, 1852	16,113,001	2,892,433	19,605,434
Government of Napoleon III., from the 3rd December, 1852, to 31st December, 1857	25,940,201	4,468,093	30,308,294
	153,644,522	36,630,240	190,274,762

Water-pipes have been made of almost every conceivable material—wood, metals, gutta-percha, india rubber, stone ware, glass, &c., but paper pipes are novelties. The new pipes, a Parisian invention, are made of paper dressed with bitumen; they are capable of resisting a pressure of 15 atmospheres, and made to bear much more by increasing the thickness of their walls. They are, of course, very light, very homogeneous, inoxidable, perfectly wholesome, and remarkably cheap. The bitumen is mixed with a certain quantity of chalk, not given, and is heated in a boiler to melting; a roll of paper is then made to pass through the liquid bitumen, and immediately afterwards it is rolled upon an iron mandril of the size desired for the interior of the pipe, to the thickness required. When this is done, the mandril is placed into another cauldron, which contains pure bitumen, and afterwards rolled upon a flat stone sprinkled with fire; the mandril is then drawn out, and the inner surface of the pipe dressed with pure bitumen. These pipes are four times cheaper and five times lighter than cast-iron. Joints are made with perfect ease, and altogether this novelty promises to be useful.

M. Morren has recently been occupied in investigating the phenomena produced by electricity on various gases, and has published the results of some of his experiments, which deserve attention. Having introduced a mixture of hydrogen and nitrogen from two mercurial gasometers, into a receiver, in which the electric spark from a Ruhmkorff's apparatus was received between two platinum wires, he produced ammoniacal gas; a solution of sulphuric acid took up the newly-formed gas and left the components in the best condition for producing a further amount; two slips of litmus paper became blue in a minute when introduced into the receiver. In a short time M. Morren was enabled to produce 13 cubic centimetres of ammonia. With a charcoal conductor and hydrogen gas, M. Morren produced carburetted hydrogen. He is now experimenting upon cyanogen, which, he says, he has repeatedly produced by his electric current alone, which seems to bring together the necessary molecules; one of the poles appearing to have a greater power than the other in this respect.

616. J. Cooke, of Cheltenham. Improvements in apparatus for giving signals on railways and vessels, and other such like uses.

Dated March 16, 1859.

662. H. Ambler, of Halifax. Improvements in breech-loading ordnance, and in the means of producing part or parts thereof, which improvements are also applicable to what are called small arms.

Dated March 17, 1859.

680. A. Mein, Glass Bottle Maker, of Glasgow. Improvements in making glass bottles, and in the apparatus connected therewith.

Dated March 23, 1859.

740. B. Browne, of King William-st., City. A new method of working or operating switches and signals on railways by improved apparatus for that purpose. A communication from V. A. Prou.

Dated March 26, 1859.

762. W. Redgrave, of Tavistock-st., Tailor. An improved pillow travelling cap.

764. S. Dreyfous and G. Richer, Civil Engineers, and E. Cornier, Merchant, all of Paris. Improvements in preserving eggs.

Dated March 30, 1859.

792. J. W. Hadwen, of Halifax, Cotton Spinner. A new art or manufacture for converting certain kinds of silk waste into yarns or threads.

Dated March 31, 1859.

806. T. Ivory, of Edinburgh, Advocate. Improvements in steam boilers, and furnaces for the same.

Dated April 2, 1859.

824. A. Riply, of Bridge-st., Blackfriars, Engineer, and J. Roberts, of Nelson-sq., Bermondsey, Engineer. Improvements in machinery for striking or scraping leather and tanned or untanned hides.

826. A. Bessemer, of Tavistock-terrace, Upper Holloway, Gentleman. Improvements in furnaces to be employed in the manufacture of iron and steel.

828. J. Skertchly, of Ashby-de-la-Zouch, Engineer. Improvements in apparatus for regulating the pressure of gas.

830. A. Paget, of Loughborough, Manufacturer. Improvements in machinery or apparatus for the manufacture of looped fabrics, and in the manner of constructing the same.

832. M. Coupland, of Haggerstone, Engineer. Improvements in furnaces.

Dated April 4, 1859.

836. J. Eccles, of Blackburn, Cotton Manufacturer. Improvements in machinery for making bricks, tiles, and other articles formed of plastic materials.

840. J. H. Burton, of Enfield-lock. Improvements in the manufacture of barrels for small fire-arms.

842. W. E. Newton, of Chancery-lane. An improved construction of retarding apparatus or break for railway carriages. A communication from A. Castellir.

844. M. A. Crooker, of New York, Engineer. Improvements in paddle wheels for steamers.

846. E. Morewood, of Enfield. Improvements in coating metals.

Dated April 5, 1859.

850. E. Fairburn, of Mirfield, of York, Card Manufacturer. Improvements in machinery for carding wool and other fibrous substances.

854. B. Browne, of King William-st., City. Improvements in propelling ships or other vessels through water. A communication from P. K. Skinner.

858. F. M. Crichton, of Stoke-bishop, Gloucester, Gentleman. Improvements in clocks or time keepers.

Dated April 6, 1859.

862. W. Owen, of Rotherham, Engineer. Improvements in the manufacture of railway wheels and tyres, and in the apparatus employed therein. Partly a communication from R. Owen.

864. J. Scoffern, of Barnard's-inn, Bachelor of Medicine. Improvements in lubricating projectiles and cartridges.

Dated April 7, 1859.

866. A. Chaplin, of Glasgow, Engineer. Improvements in steam boilers.

868. R. Wardell, of Stanwick, York, and H. Kearsley, of Ripon. Improvements in reaping machines.

870. J. Lakin, jun., of Hall-end, near Tamworth, Farmer. A new or improved agricultural drill.

872. J. Rawlings, of Carlton-hill East, Gentleman. An improved construction of boot tree.

Dated April 8, 1859.

874. W. H. Smith, of Philadelphia, M.D. Improvements in the construction of cartridges, and in the fire-arm for using the same.

876. W. Campion, of Nottingham, Machine Builder. Improvements in machinery for the manufacture of looped fabrics.

878. M. A. F. Mennons, of Paris. An improved articulated joint for water, gas, and steam pipes. A communication from V. Doré.

880. N. A. Grumel, Ink Manufacturer, of Paris. Improvements in dycing cotton, wool, silk, flax, and other fibrous materials or fabries.

882. W. Hooper, of Mitcham, India Rubber Manufacturer. Improvements in re-working or re-manufacturing compounds of india rubber and sulphur.

Dated April 9, 1859.

888. T. Barnett, of Oldham, and H. T. Sourbuts and W. Lovnd, of Hyde, Engineers. Improvements in steam engines.

890. J. Hawkins, of Lisle-st. Certain improvements in the manufacture of stirrups, bits, spurs, buckles, and other such like articles connected with harness and saddlery.

892. R. J. Derham, of Bristol, Cooper. Improvements in cheese vats.

894. C. F. Vasserot, of Essex-st., Strand. A new motive power applicable to tanneries. A communication from J. P. Lucet.

896. H. P. Gardner, of Boston, United States. Improvements in machinery for blocking or crimping the uppers of boots and shoes, and in treeing boots. Partly a communication from W. Willmott and P. Shaw.

Dated April 11, 1859.

904. A. Bower, of Liverpool, Cotton Broker. Improvements in or applicable to keels of navigable vessels.

906. R. A. Brooman, of 166 Fleet-st., Patent Agent. Improvements in candle moulds. A communication from A. Godchaux.

908. W. H. Barlow, of Great George-st., Westminster. Improvements in beams and girders.

Dated April 12, 1859.

910. W. Clark, of Langhaugh, Galashiels, Lieut. R.N. An improved safety block to be used for lowering ships' boats, the same being applicable to other like analogous purposes.

912. P. Aitchison, Brass Founder, of Sheffield. Improvements in taps.

914. E. T. Noualhier, of Paris, Manufacturer. An improved ventilator.

916. P. Hill, of Manchester, Weaver, and J. Moore, of Salford, Small Ware Manufacturer. Improvements in weaving double pile fabrics.

918. M. Castay, of Paris, Clergyman. Improvements in metallic bridges.

920. J. Ward, of King's Norton, Machinist. An improvement or improvements in working fly presses used for raising metals, coining, and other like purposes.

922. S. Tatton, of Leek, Silk Dyer. Improvements in preparing and treating silk, and improvements in dyeing silk.

Dated April 13, 1859.

924. W. A. Martin and J. Purdie, of Woolwich, Engineers. Improvements in fire bars.

928. W. Craft, of Hammersmith, and T. Wilson, of Chiswick. Improvements in the manufacture of pinafores and bibs for children.

932. J. L. Stevens, of Fish-street-hill, Civil Engineer. Improvements in the fire grates of locomotive, marine, and other furnaces.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

935. J. Luis, Welbeck-st. A new cooling apparatus for liquids, especially beer. A communication from J. L. Baudelot. Dated April 14, 1859.

988. A. W. Williamson, of University College. Improvements in making extracts from liquorice root. Dated April 19, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, April* 26, 1859.)

2845. P. Robertson. Shuttles. A communication.
2847. M. Schaffner. Smelting zinc ores.
2851. R. Whittam. Tracing designs.
2866. F. Jossa. Furnaces.
2876. J. Wardill. Controlling the running out of ropes.
2886. J. W. Friend. Flow of liquids, &c.
2887. A. Mackenzie. Sewing machines.
2888. J. J. Margaix. Galvanic batteries.
2890. R. A Brooman. Plating forks, &c. A communication.
2893. W. B. Johnson. Railways.
2902. J. Taylor. Pumps.
2920. R. Clegg, F. Angerstein, and G. Ferry. Imparting reciprocating motion.
2924. M. Kenney. Bridges.
2929. F. Ransome. Rubbing surfaces.
2952. W. B. Johnson. Generating steam.
2963. H. Lowe, W. Trueman, and J. L. Pitts. Axle.
2975. W. Taylor and W. D. Grimshaw. Regulating temperature.
2976. R. D. Kay. Colouring fabrics.
3000. R. Robin. Reaping machines.
3005. F. W. A. Casper and G. H. Schmahl. Seats.
7. J. Oliver. Lubricators.
38. W. Draper. Printing.
42. W. Corfield, jun. Chains.
59. W. E. Newton. Winding, twisting, &c. A communication.
153. R. Garrett, jun., and J. Kerridge. Thrashing and dressing machine.
177. W. E. Newton. Meter. A communication.
647. T. Patstone. Shades for lamps.
662. H. Ambler. Ordnance.
734. J. Macintosh and G. Rhodes. Tents.
765. M. Firth. Grinding saws, &c. A communication.
876. W. Campion. Looped fabrics.
935. J. Luis. Cooling apparatus. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 21, 1859.

2398. J. Luis.
2391. A. P. A. Beau.
2392. J. Kinsey.
2395. G. Speight.
2408. B. Foster and P. Smith.
2410. J. Smith.
2412. P. Brunon.
2413. W. Kirrage.
2427. E. T. Hughes.
2438. M. A. F. Mennons.
2463. G. P. Evelyn.
2478. S. Davey.
2359. J. Webster.
2898. I. Ketchum.
282. J. Hosking and T. Cock.
348. T. Moss.
404. H. Gardner.
481. J. Grimond.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

945. W. Crossley and G. Goldsmith.
953. W. Maugham.
958. A. Symons and E. Burgess.
994. C. Swift and J. J. Derham.
997. R. Lakin, J. Thompson, E. G. Fitton, and F. A. Fitton.
1003. C. A. Arnaud.
1006. T. Heiffor.
1058. I. Holden.
1097. G. J. Firmin.

PATENT ON WHICH THE SEVENTH YEAR'S STAMP DUTY HAS BEEN PAID.

1852. 452. J. Carnaby.

LIST OF SPECIFICATIONS, &c.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

LIST OF DESIGNS FOR ARTICLES OF UTILITY REGISTERED.

Dates of Registration.	Nos. in Register.	Names and Addresses.	Subjects of Design.
1859.			
Mrh. 26,	4159	Breckuell, Turner, and Sons, Haymarket ...	Candle shade.
April 4,	4160	Moore, Adams, & Pead, Friday-st.	Wrapper.
„ 5,	4161	Parker and Fell, Birmingham	Earring.
„ 12,	4162	Taylor and Alvey, Eddingley	Drill.
„ 12,	4163	H. Parrish, Birmingham.....	Pin or skewer.
„ 13,	4164	G. Jeffries, Norwich ...	Mach. for charging cartridges.
„ 14,	4165	W. W. Rouch, Strand...	Photog. tent.
„ 20,	4166	H. A. Hotden, Birmingham.....	Lamp.
„ 21,	4167	G. H. Ellis, Malton.....	Washing mach. or churn.
„ 27,	4168	J. Young, Ayr	Apparatus for sowing.
		PROVISIONAL REGISTRATIONS.	
Mrh. 25,	1062	Mason and Richards, Birmingham.....	Table expander.
„ 26,	1063	J. Newman, Birmingham.....	Tag, or fastener.
„ 29,	1064	E. Hawthorn, Ratcliff Cross	Support for lanthorns.
April 1,	1065	G. Morgan, Kingsland Road	Lens.
„ 1,	1066	A. G. De. R. Hely, Oxford-street.....	Aquarium tank.
„ 8,	1067	J. Greenish, Dorset-square.....	Photographic apparatus.
„ 20,	1068	J. Braxier, Wolverhampton.....	Lock vice.
„ 21,	1069	C. Mansel, Plymouth...	Slipper case.
„ 26,	1070	R. P. Harris, Bradford	Stool.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c. *None.*
BOILERS AND THEIR FURNACES. *None.*
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 2089, 2002.
SHIPS AND BOATS, including their fittings, 2061, 2079.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2035.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, 2060, 2076, 2114.
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2058, 2064, 2069, 2071, 2072, 2080, 2086, 2099, 2106, 2109.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 2107, 2118.
LIGHTING, HEATING, AND VENTILATING, 2087, 2088, 2119, 2120.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2068, 2077, 2078, 2093, 2104, 2105, 2122, 2123.
METALS, including apparatus for their manufacture, 2075, 2115, 2116.
CHEMISTRY AND PHOTOGRAPHY, 2067, 2070, 2121.
ELECTRICAL APPARATUS, 2110.
WARFARE, 2085, 2095, 2108, 2112, 2113.
LETTER PRESS PRINTING &c., 2103.
MISCELLANEOUS, 2059, 2060, 2063, 2065, 2066, 2073, 2074, 2079, 2081, 2082, 2083, 2084, 2090, 2091, 2092, 2096, 2097, 2098, 2100, 2101, 2106, 2111, 2117.

2058. D. CHEETHAM. *Improvements in machinery or apparatus for preparing for spinning, and spinning cotton, wool, and other fibrous materials.* Dated September 10, 1858.

This relates to an arrangement of rollers used in drawing frames, &c., and consists, 1, in raising the centres of the front pair above those of others; and by this arrangement the patentee is enabled to employ a top roller of larger diameter which will serve as a weight in itself. He also, in like manner, raises the level of the back pair. 2. In weighting the intermediate rollers. This is done by placing the weights above their axes and resting thereon. To these weights he joints levers, by which they may be raised. 3. In causing the cam, after it has revolved in one direction, to turn in the other, a traversing motion being at the same time imparted to the delivery. 4. In the application of a spring between the eccentric or crank and the comb, for bringing the connecting part back, so as to keep it in contact with the crank-pin or analogous part, whereby the concussion, which ordinarily takes place when the connecting parts become worn, is divided. *Patent completed.*

2059. W. TOSHACH. *Improvements in pile-driving machines.* Dated September 10, 1858.

These consist in so arranging them that the lift of the hammer is effected by an endless chain or chains, such chain or chains having continuous motion imparted to them (or it may be intermittent) and lifting the hammer by the contact and hold of certain parts, which parts are caused to withdraw their hold from the hammer when the required elevation has been attained, and thus producing the fall and blow required to drive the pile. Immediately the hammer has fallen the parts are in position to raise the hammer again, and this without loss of time or trouble in overhauling the chain, as in ordinary machines. *Potent completed.*

2060. P. JOURNET. *An improved toy.* Dated September 11, 1858.

This consists of a closed-up semi-circular flat box. At each of the upper flat sides there is a hole provided with a corresponding trap-door, which a spring tends to keep shut. There is a small cross bar at each end with a pin inserted in the two opposite sides of the box towards the centre: from this bar an arc or semi-circular or curved plate, or strong wire provided towards the middle of its length with a counter weight, is hanging by a wire, whereas at each end of this arc is fixed a grotesque figure, so that by the effect of the see-saw motion that may be imparted to the arc the said figure will alternately strike against the doors, and thus opening them alternately present themselves to sight. *Patent abandoned.*

2061. L. HILL. *Improvements in apparatus for lowering or paying out ships' chains and anchors.* Dated September 11, 1858.

The patentee constructs the windlass purchase or capstan so as to give out chain under the regulation when desired of a brake or friction strap. *Patent completed.*

2062. W. BAKER. *Improvements in preparing food.* Dated September 11, 1858.

This consists in combining the following ingredients:—Indian meal, locust beans, oatmeal, rice, carbonate of soda, tumeric, carraways, ginger. *Patent abandoned.*

2063. F. GIESBERS. *Improvements in the manufacture of coke.* Dated September 11, 1858.

Here peat is employed, which, when dry, is saturated with coal tar or pitch, or Trinidad pitch. The peat thus saturated is first subjected to a moderate heat (say from 700 deg. to 800 deg. of Fah.) in retorts or ovens, for some length of time, and then the heat is increased up to a low cooking heat by which the mass is converted into coke. *Patent abandoned.*

2064. J. M. COURTAULD. *An improvement in clearing and preparing silk crapes, aerophanes, and other like fabrics, lisses and other gauzes and lace, and in machinery employed therein.* Dated September 11, 1858.

This consists in bringing the surface of the fabric to be "cleared" in contact with another part thereof, or of a similar fabric, and then separating the surfaces by the following machinery. Upon a frame the patentee mounts two rollers clothed with india-rubber; the bearings of one roller are fixed, while the bearings of the other are free to move towards and from the fixed bearing; a weight or spring is employed to keep the rollers together. One roller is driven, while the other revolves by frictional contact. He introduces perforated gas and steam pipes under the rollers, to obtain heat or moisture under the crapes. A piece of crape, &c., is mounted upon one roller, and one end connected to the other roller, and the machine set in motion; the crape unwinds from one roller and winds upon the other roller, and the contact and separation of the surfaces of the crape perform the clearing. *Patent completed.*

2065. H. PAGE. *An improved crown or round glass, and apparatus for manufacturing the same.* Dated September 11, 1858.

This consists in manufacturing crown or round glass without the "bullion." *Patent completed.*

2066. J. L. HINKS. *A new or improved tap or cock for drawing off and filtering liquids.* Dated Sept. 11, 1858.

The patentee describes a tap or cock in which the liquid, before being drawn off, is made to pass into a chamber divided by a diaphragm, or partition of filtering material, a pipe and valve being connected with each of the two parts into which the chamber is divided by the filtering material, so that by opening one or other of the valves, the liquid may be drawn from the said chamber either without filtration, or be made to pass through the filtering material. *Patent completed.*

2067. H. WIKOFF. *A new tonic medicine for the cure of coughs, and diseases of the chest.* (A communication.) Dated September 11, 1858.

This consists in extracting the sap from the maritime pine, and administering it as a tonic medicine in given quantities, either in its natural state, or when clarified, or after having been made into a syrup. *Patent abandoned.*

2068. W. H. MANNING. *Improvements in candlesticks or holders.* Dated September 11, 1858.

This consists in having a moveable binding plate suitably curved and shaped, placed within and at one side of the socket, and so arranged that it can be made to press the end of the candle against the opposite side of the socket of the candlestick or holder, and so to hold it secure. *Patent completed.*

2069. L. KABERRY and T. MITCHELL. *Improvements in machinery or apparatus for preparing for spinning, and spinning cotton, wool, and other fibrous materials.* Dated September 11, 1858.

This relates, 1, to the differential motion of slubbing or roving frames, and consists in the use of an extended boss for carrying the wheels. 2, in forming the bobbins for preparing machinery of metal; 3, in a method of balancing the lifting rail of slubbing or roving frames; and, in reference to machines of the male class, causing the material to be delivered by the rollers in a variable degree, as the cop increases in size, and particularly for that purpose the employment of a travelling inclined plane. The parts of the invention are not described apart from the drawings. *Patent completed.*

2070. W. GOSSAGE. *Improvements in the manufacture of soda and potash.* Dated Sept. 11, 1858.

This relates to a previous patent dated 21st August, 1857, and consists in a method of extracting sulphur from alkali waste by the agency of carbonic acid gas; also in a method of obtaining the carbonic acid gas. *Patent abandoned.*

2071. W. THOMSON. *Improvements in bleaching yarn, warps, or similar materials.* Dated September 13, 1858.

The patentee passes the yarn or warps, previous to being sized, through a weak solution of chloride of lime, or chloride of soda, and then either over hot cylinders to dry the material, or through a steam chest, either of which will cause the bleaching liquor to act on the yarn, and bleach it. He then passes it through rollers in water to wash off the lime, soda, or other agent, and the yarn is ready for sizing. *Patent completed.*

2072. G. FLAGEOLLET. *Improvements in self-acting mules.* Dated September 13, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2073. J. B. A. DUCLERE. *A new method of separating solids from liquids for disinfecting purposes.* Dated Sept. 13, 1858.

This consists in the employment of magnesia, salts, metallic precipitates, and phosphoric and amoniac acids, the said products being employed for manure or other useful purposes. *Patent abandoned.*

2074. C. W. SIEMENS. *Improvements in refrigerators, and in the treatment of the freezing or cooling material or materials used therewith.* Dated September 13, 1858.

These have reference to that description of apparatus in which the freezing is produced by dissolving chloride of calcium, &c., and consists in constructing such refrigerators of a series of vessels fitting one within the other, and of an annular form, so arranged that the solution shall be gradually produced by a current of fresh or salt water passing upwards through a tube, and distributed from the top of such tube, so as to spread itself amongst, and afterwards descend through the body of the salt, and gradually pass away from the apparatus; and so that in its circulation it shall, 1, come in contact with removeable vessels containing the liquids or material to be frozen, and, 2, in contact with a compartment through which water, &c., may circulate for being cooled, and further in contact with removeable articles, such as bottles, or jars, or solid objects for cooling them also. It also consists in constructing the vessels above mentioned of a long and narrow taper form, circular or otherwise in section, covered at the upper end and closed at the bottom with a moveable cork or elastic plug to prevent bursting when solidification ensues, and allow the contents to be removed. *Patent completed.*

2075. S. HANBURY. *An improvement in the manufacture of tubes of copper, brass, and other metals.* Dated Sept. 13, 1858.

This consists in making tubes thicker at both ends than in the centre, to afford facility for fixing them. *Patent completed.*

2076. R. FROST and A. RIGG. *Improvements in apparatus for cleaning grain or seeds and bran.* Dated Sept. 13, 1858.

Here the screen or riddle of a machine is made of a corrugated form, and the grain is caused to meet a blast of air in an upright or vertical spout. The direction or action of the air-blast is governed as it enters the upright or vertical spout by louvre boards, and the quantity of air admitted to the fan or blower is regulated by flap doors over the inlet openings. These doors are controlled in their action by balance weights, so that by the combined action of the air and the apparatus applied to the doors the admission of air is regulated. The grain or seed is equally distributed to the blast by a fluted roller. The inner coating of flour is removed from bran by metallic scourers, roughed in the

Digitized by Google

manner of an ordinary grater, and is formed on a flat surface. *Patent completed.*

2077. J. TURNER. *Improvements in the manufacture of hats.* Dated September 13, 1858.

Here the patentee uses for the "tip" or "brim" prepared grass, or straw, or the article known as Brazilian chip, or palm leaf, not making the side of the hat of this material, but of the materials usually used. *Patent completed.*

2078. J. W. TOWELL. *An improved helmet.* Dated Sept. 13, 1858.

This consists in forming the same of two or more layers of cork united by intermediate layers of cloth coated with gum, shellac, &c., a block or mould being employed for producing the desired shape, whereby a union of the cork and intermediate cloth is effected, and the necessary strength and durability obtained, in connection with which the head-leather or lining, with suitable perforations, is so arranged as to admit air passing through the same into the body of the helmet for ventilation. *Patent abandoned.*

2079. C. J. REDPATH. *Improvements in ships' and other pumps.* Dated Sep. 14, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2080. W. RILEY. *Certain improvements in looms.* Dated Sep. 14, 1858.

These consist, 1, in a warp-break or series of rollers for carrying and guiding the warp. 2, in the addition of a measuring apparatus. *Patent completed.*

2081. L. VIDIE. *Improvements in apparatus for measuring the pressure of fluids by the flexion of diaphragms.* Dated September 14, 1858.

This consists 1, in using two corrugated tubes soldered at their lower ends to a stationery plate, and closed at their upper ends by an annular plate, by which the pressure is lessened on tubes of a given diameter, and such tubes may be made thinner or more flexible. 2. In combining flexible plates with corrugated tubes (forming the covers or closings) if a great deflexion is required. The invention also includes other improvements which are not described apart from the drawings. *Patent completed.*

2082. J. LUIS. *Coke and gas kilns.* (A communication.) Dated September 14, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2083. J. LUIS. *A new system of moulding without foundry pattern.* Dated September 14, 1858.

This is applicable to the moulding of cog-wheels, and consists principally in hollowing out in sand, by a revolving plane table turning round a fixed centre, a circular space, having for depth the height of the wheel, and for thickness that of the felloe of the wheel, reckoning the teeth. In this hollow are placed several cores, moulded separately, and having the form of the openings between the teeth at equal distances one from the other by means of an apparatus similar to a graduating machine. *Patent completed.*

2084. W. J. HOYLE. *Improvements in arrangements and mechanism or apparatus for signalling by sound.* Dated September 14, 1858.

This relates to that system of sound signals produced by an instrument having the character of the whistle, and consists—1, in applying to the ordinary steam whistle reflectors similar to those used in reflecting light, for concentrating and throwing out the sound vibrations produced by the whistle all round in a horizontal plane; 2, in applying to the ordinary steam whistle a reflector for concentrating and throwing out the sound vibrations in one direction, the reflector being arranged on a vertical axis, so that it can be rotated by hand, or self-acting mechanism; 3, in self-acting arrangements for producing sounds or signals by a whistle of any given duration, and at any given intervals. *Patent abandoned.*

2085. G. C. GRIMES. *Improvements in fuses, and in the means of manufacturing fuses.* Dated Sept. 14, 1858.

This relates—1, to forming the paper, &c., upon which the ignitable composition is applied of a disc, square, lozenge, or other form, upon the end of a short length of wire, so that whilst the head of prepared matter is capable of being held by the wire as a stem when friction is applied thereto, such stem may be readily pushed through the head to serve as a means of connection to a cigar either before or after ignition; 2, to means by which lengths of wire may be applied as stems or holding means to fuses; 3, to forming fuses of that kind produced of slips of prepared paper or such like material, with part of the length of such slips thinner than the other for obtaining elastic pressure thereto when in use; 4, to the composition or matters applied to the ends of splints of wood, &c. *Patent completed.*

2086. R. LAKIN and J. WAIN. *Improvements in spinning mules, and other machines of that class, used for spinning cotton and other fibrous substances.* Dated Sept. 14, 1858.

These consist—1, in a means of causing the driving strap to be partially traversed on to the fast pulley, at the time when the friction cones used for backing-off are taken out of contact with each other, and of regulating the time of the strap remaining on the fast pulley; 2, in an apparatus for varying the speed of the backing off; 3, in attaching a cam to the faller-shaft to act on one end of a lever connected to the counter faller finger, so as to regulate the motion given from the counter faller for governing the winding-on; 4, in the application of a spring or weight to the pulley on which the cord or strap for regulating the winding-on moves, for keeping the cord or strap at an uniform tension; 5, in an improvement in the self-acting mules known as Robert's mules, so that during the outward run of the carriage the driving strap may be traversed from being partially on the fast and partially on the loose pulley to be on the loose pulley only, without the intervention of the cam shaft. The invention is not fully described apart from the drawings. *Patent completed.*

2087. A. H. J. BARIABLE. *Improvements in apparatus employed in the production of light.* (A communication.) Dated September 14, 1858.

This relates to apparatus for the production of light in which jets of ignited gas are projected against a surface of lime, &c., to which a slow motion is given. The patentee encloses a column of lime, &c., in a case or guard, along which the column of lime, &c., may be impelled, the case or guard extending above as well as below the opening at which the jet or jets of flame strike the lime, &c. At this opening in the case he fixes wires, so that the lime, &c., upon which the flame or flames may happen to be impinging shall not fall down or out of the case when it happens to crack or depreciate by the action of the flame. By these means he is enabled to prevent a great deal of the irregularity in the light which would be occasioned by the breaking away or the decrepitating of the lime, &c., by the action of the flame. *Patent completed.*

2088. S. S. MASSIA. *Improvements in stoves, or fireplaces.* (A communication.) Dated September 14, 1858.

Here certain openings at the sides and back of the grate are so situated and arranged as to conduct the smoke with certainty into the chimney. The stove or fireplace is set in an inclosed chamber, and there is no opening into the chimney except through a tubular passage which rises from an upper opening. *Patent abandoned.*

2089. Hon. W. E. COCHRANE. *An improvement in the fastenings of railways.* Dated September 14, 1858.

This consists in the introduction of pins or rods of a hard material which will not sink transversely through the wood fastenings, so that the ends of the pins or rods may come flush with the sides of the wood fastenings. By these means, when a wood fastening is driven in between the cheek of a railway chair, and a rail or rails therein, the the ends of the pins will come in contact with the inner surface of the chair and with the rail or rails therein, and will, notwithstanding the shrinking of the wood, still retain the rail or rails secure. *Patent completed.*

2090. F. FOWKE. *Improvements in fire-engines.* Dated September 15, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2091. E. SMYTH. *Improvements in swimming belts and life preservers.* Dated September 15, 1858.

This consists 1, in employing a hollow inflated belt or float, composed of vulcanised india-rubber, and provided with suitable bands, or straps, to attach it to the body. 2, in employing several separate belts or floats, each inflated by a separate flexible tube, the other or mouth ends of these tubes being traced side by side to each other, and to the mouth-piece of a float worn by the person in charge of the compound float. *Patent completed.*

2092. E. DORSETT. *A portable carriage tank and furnace, to be employed for the purpose of creosoting hop-poles or other timber.* Dated September 15, 1858.

The inventor employs a portable carriage for carrying the tank, creosote, and furnace to any desired spot, so that the poles can be dipped and creosoted, and the carriage or machine afterwards moved onwards to the next position where creosoting is required *Patent abandoned.*

2093. W. G. TAYLOR. *Improvements in the manufacture of gloves.* Dated September 15, 1858.

This consists in the manufacture of gloves from rabbit or hare skins. *Patent completed.*

2094. Provisional protection for this invention was refused.

2095. G. REDFORD. *Making cartridges of metal, or gutta percha, with or without bullets, and for other purposes.* Dated September 16, 1858.

Here pieces of metal or gutta-percha, are first struck in a die so as to produce the requisite shape of the bullet or blank cartridge, and to form part of the tubular portion, which is afterwards elongated by being placed in a steel bed, and forced through by a plunger. When it is required to produce cases for containing various substances, a neck and opening are given, by changing the form of the die and punch accordingly. *Patent abandoned.*

2096. R. ALLISON. *Improvements in apparatuses for boring and sinking.* Dated September 16, 1858.

Here the boring head or tool is hollow, and of wrought or cast-iron, furnished at bottom with a series of chisels. Inside the tool, and near the end where the cutters are fixed, is a valve of india-rubber, &c., the edges of which rest upon a ledge fixed on the inside of the tool. To the side of the tool a door or trap is fitted, the bottom of which is in a line with the valve seat. The top of the tube carries an ordinary bow sling, whereby to connect it to the rope or chain for imparting motion to the tool. Wooden blocks are fitted to the outside of the tool to act as fenders. For raising the débris the inventor employs a vessel consisting of two cylinders, one over the other, and the upper cylinder capable of sliding inside that under it; the bottom cylinder has a valve opening inwards, and over the top of the upper cylinder there is a similar valve. The cylinders are held in a frame, and are connected to a rope or chain. Upon the pump being lowered, the upper cylinder will fall within the lower; then upon this upper cylinder being raised, a partial vacuum will be formed, whereupon the debris will flow into the lower cylinder, and be there retained by the bottom valve falling back upon its seat, and closing egress from the bottom of the cylinder. A joint in the frame permits of the lower cylinder being tilted, to empty its contents. *Patent abandoned.*

2097. W. P. STRUVE. *Improvements in apparatus for indicating strains on engine ropes or chains.* Dated Sept. 16, 1858.

Here a pulley or sheave is mounted in a frame which slides freely in two upright guides. The pulley or sheave frame has a chain or rope attached to it which passes over two guide pulleys, and it has two counter balance weights attached thereto by which the pulley or sheave and frame are raised. The weights are sufficient to cause the engine chain or rope when working at the proper strain to be raised or deflected a few feet out of the straight line. At the lower, and also at the upper part of the upright guides in which the frame slides, is applied a lever having a wire communicating with a bell. In the event of the engine rope or chain being subjected to any excess of strain, whether when the waggon is ascending or descending the plane, it ceases to pull on the rope, the bell will be sounde by the frame which carries the sheave coming against th lower or upper lever. *Patent abandoned.*

2098. J. R. SCARTLIFF. *An improved burglars' detector.* Dated Sept. 17, 1858.

This consists of apparatus which, being placed in any part of a house, and made to communicate by a series of cords or wires passing from it with other portions of the building, such as doors, windows, safes, drawers and boxes, will, upon any of these being opened, or tampered with, be thrown into action in such a way as to give an alarm, and, striking a light when such is necessary, indicate accurately the portion of the building or article within it so acted upon. The invention is not described apart from the drawings. *Patent completed.*

2099. C. F. VASSEROT. *Machinery or apparatus for dressing and finishing fabrics.* (A communication.) Dated Sept. 17, 1858.

This consists in passing the fabrics 1st, over rollers where it receives the dressing liquor, and next submitting it to the action of the "beetle." For dressing linen or cotton fabrics the patentee suppresses the beetle, and substitutes a pair of copper rollers (hollow), so that the material, having first received the dressing solution, is caused to pass between the two rollers, which are heated by steam, and is by them pressed and dried. *Patent completed.*

2100. G. PRAX. *Improvements in apparatus for separating the liquid from the solid portions of fecal matters.* Dated September 17, 1858.

This relates to a moveable apparatus to be applied to the pipe by which the fecal matters from water-closets are conducted to the sewers, thereby allowing the liquid portions only to run off in the sewers, whereas the solid parts remain in the apparatus, which latter may be removed and replaced by an empty one. *Patent abandoned.*

2101. E. WELCH. *An improved tobacco press.* Dated September 17, 1858.

This relates to pressing tobacco by a hydraulic press. The patentee fits the press with a railway, upon which the mould traverses. Secured to the head of the press is a block which fits the mould loosely. Immediately below this block the ram of the hydraulic cylinder is situated, and over it is placed the mould. As the ram rises under the action of the fluid injected into the hydraulic cylinder, it will lift the mould from the railway, and cause the tobacco therein to be pressed into a cake by the block on the press lead. *Patent completed.*

2102. C. HADLEY. *Improvements in omnibuses, cabs, railway carriages, waggons, and other similar vehicles.* Dated September 17, 1858.

This consists, 1, in constructing the above mentioned vehicles with a lower centre of gravity than hitherto, and of forming a separate compartment on the roof of (or underneath) the present carriage; 2, in modifications of the springs, axles, wheels, and other parts of carriages. *Patent completed.*

2103. J. H. GRESHAM. *Improvements in copying letters, invoices, and other writings.* Dated Sep. 17, 1858.

Here the writing to be copied is written in any suitable copying ink, and the copying paper damped with water, and the letter placed in juxtaposition to it, and the oiled sheets are employed for preventing the ink from spreading to other parts of the book or paper. The book or copying sheets being thus prepared, and the letter, &c., deposited in its place thereon, the pressure is applied by a roller, the inner part of which may be free to revolve on a centre, whilst the ends are held in the hands of the operator. After this roller has been passed once or twice over the copying paper the letters will be found to be perfectly copied. *Patent completed.*

2104. G. OSTERMOOR. *Ornamenting boas, victorines, and muffs.* Dated September 18, 1858.

Here the ornamentation of the said articles made of velvet or plush is executed by pressing or embossing figures, ornaments, or devices on them in the ordinary way; or the inventor performs the same during the process of printing or weaving by printing the figures on them or weaving them in during their manufacture. *Patent abandoned.*

2105. J. LUIS. *Improvements in the application of gutta percha for clogs, goloches, shoes, and boots, and for the apparatus connected therewith.* Dated Sep. 18, 1858.

The gutta-percha is put in a boiler placed on the fire, where it becomes nearly liquid or half fluid; in this state it is run into a mould, when by a common screw press adapted to the moulds, the matter is obliged to spread itself equally in all the empty parts. The whole is then allowed to cool for about ten minutes, the gutta-percha solidifies, and the shoe, boot, or goloche is thus made in one piece and at very little expense. *Patent completed.*

2106. J. LUIS. *A new manner for applying centrifugal force in the manufacture of the fecula of potatoes, of starch, of yeast, of porcelain paste, of paper pulp, and ultarmarine, and the apparatus for carrying out the same.* (A communication.) Dated September 18, 1858.

On the interior mantle of the drum of the apparatus the patentee applies a thickness of metallic coarse cloth. A tissue of ozier or wicker can be used as well. If the drum is of sheet iron pierced with holes in the vertical mantle, these holes can have about one-eighth of an inch in diameter. On this surface is applied a metallic cloth, and on this sheet iron is put a tissue made of linen, wool, or cotton sufficiently fine to retain the fecula or starch while the water filters through. There are modifications included. *Patent completed.*

2107. J. G. N. ALLEYNE. *Improvements in the manufacture of wrought-iron beams and girders.* Dated Sep. 18, 1858.

The patentee makes wrought-iron beams and girders in two or more pieces, united by scarfed, or notched, or lapped, or diagonal joints. Thus he rolls two pieces of wrought-iron, each of which has a flange or enlargement at one edge, and has its other edge bent or formed so as to fit to the corresponding edge of the other piece of iron. *Patent completed.*

Digitized by Google

2108. J. B. BEASLEY. *Improvements in the construction of sporting and all other guns.* Dated September 18, 1858.

The patentee attaches to the stock of the gun, rifle, or musket, a sliding bolt or stop, which is always kept forward by a spring. The end of this sliding bolt or stop projects forward sufficiently far to catch the hammer of the lock of the gun, rifle, &c., to which it is attached, and thus prevents the hammer from striking the cap upon the nipple when by accident or neglect it falls. In connection with the sliding bolt or stop is a depressing lever or plate. This lever or plate is let into that portion of the stock which is held by the hand, the first finger of which pulls the trigger, and is so arranged that when the hand grasps the stock it is depressed, the consequence of which is that the bolt or stop is withdrawn, and the hammer is free to strike the cap placed on the nipple. *Patent completed.*

2109. A. TURNER. *Improvements in looms for weaving.* Dated Sept. 18, 1858.

This relates to a mode of constructing the shuttles used in weaving narrow fabrics, and also the planks, batten, or slay in the grooves of which the shuttles work. *Patent completed.*

2110. H. W. GRYLLS. *Improvements in apparatus employed in submerging or laying down electric telegraph cables.* Dated Sept. 18, 1858.

Here the cable is passed through a strong metal guide-ring, which is suspended to the stern of the vessel by chains, &c., of any required length. To this guide-ring is attached a second ring formed of two or more segments connected together by hinges, and constructed so that when a chain or rope attached to one segment is drawn tight by means of this apparatus on board the vessel, the segments collapse and grasp the rope firmly between them. The portion of cable so held may then be drawn on board to be spliced or repaired. By these means in case of fracture the submerged portion of the cable would not be lost. *Patent completed.*

2111. T. VICARS, sen., and T. VICARS, jun., T. ASHMORE, and J. SMITH. *Improvements for the consumption of smoke in moveable furnaces or chauffers for heating bakers' and other like ovens.* Dated September 18, 1858.

Here the box or ash-pit of the chauffer is surrounded by air passages, which supply air that passes between a shell or box that surrounds the chauffer or fire-box; this outer shell is about half the height of the chauffer. The air ascends along the outer sides of the chauffer, and mingles at the top with the gases from the fire, and thus prevents smoke. *Patent completed.*

2112. J. L. CHESTER. *An improved cartridge opener and ramrod fastener.* (Partly a communication.) Dated Sept. 20, 1858.

This consists in constructing a flat spring with an edge bent nearly at right angles, with its flat surface serated or toothed, and attaching one end of it to some convenient place on the stock or barrel near the muzzle of the gun or pistol, while the other end is only controlled by a pin formed on it at right angles to the flat face, which here is made broader and suitable as a thumb-piece. This pin, the purpose of which is to keep the spring steady and in place, plays into a slot or socket in the gun. When the cartridge is to be opened, its proper end is inserted between the barrel and the toothed edge, which, by the pressure of the thumb on the spring, closes upon and holds it fast, while the paper is being torn away so as to expose the powder. *Patent abandoned.*

2113. H. BARROW. *An improvement or improvements in cartridge-boxes.* Dated Sept. 20, 1858.

The patentee claims, placing a partition or diaphragm in the said boxes, the said partition or diaphragm having holes or perforations capable of expanding when the cartridges are forced therein, in which holes or perforations cartridges of various sizes are held so securely as to be prevented from falling accidently out of the box, but which cartridges may be readily removed from the box without risk of injury thereto. *Patent completed.*

2114. H. FIRMIN. *A machine for cleansing chaff and other food for horses and cattle.* Dated Sept. 20, 1858.

This machine is intended to clean chaff, &c., when cut for food for horses and cattle, from dust and dirt, and consists of a perforated zinc, or other open work metal cylinder, open at both ends, inside which a shaft armed with brushes, or other agitators, is made to rotate, whereby the chaff, &c., will be stirred, so as to remove the dust and dirt therefrom, which, by the action of the brushes, will be forced or sent through the perforations out of the cylinder. The cylinder should be placed at a slight angle from the horizontal line. *Patent completed.*

2115. E. RIEPE. *An improvement in the casting of steel.* Dated September 20, 1858.

This invention is an improvement upon two inventions formerly patented by E. Riepe, 9th July, 1853, and consists in heating the mould prior to pouring in the steel. For hard and soft steels different degrees of heat will be required. *Patent abandoned.*

2116. G. M. LEVI. *Improvements in the manufacture of iron in the blast furnace.* (A communication.) Dated September 21, 1858.

By this invention the blast which may be hot or cold, is alternately stopped and put in action at regular intervals, and the charge of fuel is subsequently reduced; and it has been found by experiment that a very considerable saving of fuel is the result. The reducing action of the fuel continues while the blast is stopped. The ordinary blast furnace may be used, but if the tuyeres are at or below the level of the dam they ought to be raised so as to prevent the cinder from entering them when the blast is stopped. *Patent completed.*

2117. T. COOK. *Improvements in the method of preparing and securing bankers' and other crossed cheques against fraudulent erasure or removal.* Dated September 21, 1858.

This consists in piercing or puncturing the paper wherever any writing occurs. *Patent abandoned.*

2118. G. DOWLER, and T. T. CHELLINGWORTH. *An adjustable torsion spring for doors or other purposes.* Dated September 21, 1858.

This consists in applying a rod of steel attached at one end to a bracket of brass or iron fixed to the door-post or frame. The other end is fixed to a similar bracket attached the door. When the door is opened the steel rod is twisted, the twist acting as a spring. At the end of the rod that is fixed to the bracket attached to the door frame or post is a small wheel, or round nut, with notches formed in it, and a catch is attached to the bracket which fits into any of the notches on such wheel or nut. A key or handle fits to the end of the rod that is filed square for the purpose. *Patent abandoned.*

2119. L. DE PARIENTE. *Improvements in apparatus to be applied to gas burners, with the object of increasing the lighting power of the gas flame.* (A communication.) Dated September 21, 1858.

This relates to the adaptation to gas-burners of an apparatus for increasing the illuminating power of the gas-flame, by dividing this latter, and causing an introduction of air into the flame, thereby imparting a greater heat to the lower or blue part of the frame, whereby the lighting effect is increased without increasing the consumption of gas. The invention is not fully described apart from the drawings. *Patent completed.*

2120. J. C. E. MALVEZIN. *Improvements in the manufacture of tubes, pipes, or mains for conducting liquids or gas, or for other similar purposes.* Dated September 21, 1858.

This consists in manufacturing such tubes of tissue or yarn of cotton, impregnated with bituminous matters. *Patent abandoned.*

2121. J. BETHELL. *Improvements in treating pyrites.* Dated September 21, 1858.

This consists in obtaining of sulphuret freed from the coal, and other matters, and in nearly a pure state of sulphuret, and he produces this result by grinding the sulphurets into small pieces with a pair of iron rollers, and then washing such ground materials with water in any of the machines now used for washing coals and ores. *Patent completed.*

2122. A. V. NEWTON. *An improved machine for sweeping carpets and floors.* (A communication.) Dated September 21, 1858.

This relates, 1, to the combination of a cylindrical brush, the bristles of which are by preference inclined at an angle of about 45 deg. from a radial line passing directly outward from the centre of the axis of the brush, with a traction-roller in the construction of a machine for sweeping carpets and floors. 2, to a peculiar construction of traction-roller, by which a certain and efficient traction and adhesion, combined with smoothness of action, is secured at a trifling expense. *Patent completed.*

2123. J. DEWRANCE. *An improvement in the construction of pianoforte frames.* Dated September 21, 1858.

This relates to a construction of pianoforte frames, whereby the tendency of the frames to twist under the strain of the strings will be effectually counteracted. It applies both to metal and wooden frames, although the patentee prefers the use of metal frames, as they contract and expand, like the strings, under differences of local temperature. *Patent completed.*

IRON AND OTHER METALS.

[FROM OUR OWN CORRESPONDENT.]

The Iron Trade Generally; how influenced by politics.—The South Wales District.—The Districts of Yorkshire, Derbyshire, and Lancashire.—Glasgow Market.—South Staffordshire Trade.—On 'Change at Wolverhampton and Birmingham; the question of Future Prices.—The Hardware Trades in the Midland and Sheffield.

NOTHING satisfactory can this week be reported of the iron trade beyond a somewhat stronger hope on the part of masters than existed last week in the future peaceful attitude Great Britain in relation to the war in Italy. The effects of the disturbed state of the Continent, and of the political unrest at home, is being felt in all the districts to the disadvantage of each, as well in the decrease of the numbers and value of orders, as of an expectation by most consumers that their orders will be executed at lower rates.

A tolerably favourable account, however, continues to arrive from South Wales; where it is stated that the leading works have recently been put in possession of orders that will afford employment to most of the machinery for some time to come.

In the united districts of Derby, York, and Lancaster counties, as in South Wales, considerable quantities of railway iron are being turned out; but in other respects a slackness prevails. An ordnance commission has been received by a Yorkshire house.

At Glasgow, on Tuesday, all descriptions of pig iron were nominal at 51s. The quantity shipped in the previous week was an increase upon that of the corresponding period last year, the figures being this year 16,500 tons; last year, 15,100 tons.

At Birmingham to-day (Thursday) and at Wolverhampton yesterday there was marked inactivity. The war about to open on the continent and the elections at home are all-powerful to prevent the transaction of any amount of business that can be quoted. Masters and agents have pretty well made up their minds to receive this state of things as philosophically as possible. An utterance of loud complaint is, therefore, voluntarily stifled. The only point which calls for remark is the probability of the future. On every hand there is a deep feeling in favour of neutrality, with consequent satisfaction at the peaceful assurances of the noble Premier at the Mansion-house on Monday night. His Lordship's remarks on Monday night, it was evident at Wolverhampton and Birmingham, had allayed some little of the anxiety which was beginning to manifest itself at those places last week, as the result of the tone of Lord Derby's remarks just prior to the dessolution. There is a steadiness in the demands of some of the best customers of the first class houses, but the quantities are smaller than usual, without, however, a demand for the accepting lower rates, These favourable instances are not, however, universal. On the part of speculators there is an evident expectation that malleable iron will be got for less money before the end of the quarter than that now asked. American continues slow in her demand. There are a few instances in which pigs have realised £3 15 0, but they cannot at present be quoted at above £3 12 6 for mine iron.

The holidays and the elections have come to the relief of some employers in the hardware trades of Birmingham and Wolverhampton, who will thereby be enabled to spin out the few orders that are in hand until it is trusted that others will have been received.

In Sheffield there is an indisposition on the part of manufacturers to enter into large contracts from other than houses respecting whom whatever may be the consequences of the continental struggle there is no room to doubt. Some of the rolling mills are tolerably well off for steel of small samples, and the edge-tool makers have recently received some good orders.

LIST OF MISCELLANEOUS TENDERS INVITED, AND ENGAGEMENTS OPEN.

The tenders and vacancies which appear in this weekly list are not repeated in succeeding numbers.

DOCK WORKS, *Hull.*—For increasing the depth of water in front of the Corporation-pier. Plans, Office of Captain Cator, R.N., Pilot office, Hull, to May 4. Tenders, May 5, to the Dredging Committee.

GAS-WORKS, *Lindfield, Sussex.*—Plans with the Lindfield Gas-light and Coke Company. Tenders, May 10.

WATERWORKS AND SEWERAGE OPERATIONS, *Stoke-upon-Trent.*—Including the providing of iron tank. Plans, &c., at Parish-office. Tenders, May 4.

WORKS, *Woolwich.*—For renewing lead-gutters and roofing at the Royal Military Academy. Plans to May 10. Tenders to May 12.

ROADS, *Brackley and Towcester.*—For lowering Furfordhill and Burcott Wood-hill. Sections, &c., Messrs. Charles and G. Cave, surveyors, Banbury. Tenders, May 3.

ROADS, *Worcester.*—For lowering Broadheath-hill, Henwick district, about 500 yards. Plans, Mr. Martin Curtler, Sansome-place, Worcester. Tenders, May 4.

IRON GAS-PIPES.—The Dakinfield Gas Company want a supply of 7-inch cast-iron main-pipes. Apply to Mr. Dore, at the Works.

COALS, *Navy.*—For her Majesty's Dockyards and Victualling-yards, Naval Hospitals, Royal Marine Barracks and Infirmaries, and the Admiralty Marine and Coast Guard Offices. Tenders to 2 o'clock, May 3.——South Wales coals also required for her Majesty's steamvessels, St. Vincent, Cape de Verde. From June 1, 1859. Tenders, May 10.

GREEN HEART TIMBER, *Mersey Dock Estate.*—60,000 feet of large scantling. Application for particulars to the engineer, Mr. B. Hartley, Dockyard, Coburg Dock. Tenders to June 18.

ROAD MATERIALS, *London.*—The Commissioners of the Metropolitan Roads want materials. Particulars, 22 Whitehall Place. Tenders, May 10.

SEWERAGE WORKS, *Preston.*—922 yards of brick sewer, and 850 yards of 18-inch pipe sewer.

CONVENT, *Ireland.*—At Kenmare, county Kerry. Plans, &c., from May 2, at Very Rev. J. O'Sullivan, P.P., Kenmare; or to the architect, C. Hansom, Esq., Clifton. Tenders to May 14, to Rev. John O'Sullivan.

POLICE-STATION, *Gainsborough.*—With magistrates' room, &c. Plans, &c., Michael Drury, architect, 1 Bank-street, Lincoln. May 17.

THE SAME, *at Torpoint, St. Cleer, and Menheniot.*—Together or separately. Plans, &c., for Torpoint, from the Serjeant of the County Police there; from St. Cleer and Menheniot, from the Inspector of County Police, Dalwalls, near Liskeard. Tenders, May 7.

CEMETERY CHAPELS, &c., *Darlaston, South Staffordshire.*—Consecrated chapel, with tower and spire, and vestry-room; an unconsecrated chapel, with vestry; a sexton's house, &c. Tenders to Clerk of Burial Board, Darlaston, May 6.

SCHOOLS, AND TEACHERS' RESIDENCE, *Newmarket.*—Drawings, &c., Mr. R. Lloyd Williams, architect, Hulian Place, Denbigh, until May 2. No date given.

THE SAME, *Rudham.*—Plans at Crown Inn, East Rudham; or at the offices of Messrs. Clowes and Howerdew, Bank Chambers, Norwich. Tenders, May 4.

RECTORY HOUSE, *Carsington, Derby.*—Near Wirksworth. Plans, Rev. J. H. Brett, Wirksworth. Tenders, May 7.

SHOPS, *Burslem.*—Four shop premises. Plans, &c., Messrs. Ford and Mayer, architects, Burslem, on and after May 4. Tenders to May 9.

FARM BUILDINGS, *Stafford.*—At Redhill. Plans, &c., Mr. Kenderdine, Brook-house, Stafford. Tenders, May 4.

HOUSE, *Harrowgate.*—Dwelling-house, stables, &c., Belmont. Plans, &c., Messrs. John Child and Son, 24 Park-row, Leeds, to May 3, and at Tenter Lodge, Knaresboro', from 4th to 10th May. Tenders to May 11.

COTTAGES, *Redhill.*—The time for receiving tenders for the cottages for the Redhill and Reigate Cottage Improvement Society has been extended to May 5. Drawings, &c., at office of architect, Mr. E. Baxendell, 7 Beaufort-buildings, Strand, London, W.C.

CEMENT AND PLASTER KILNS.—The Marple Mineral Company want a contractor to build cement and plaster kilns at their works, Marple, near Stockport. Address to J. Ryde and Co., Great Marlborough-street, Manchester.

WORKING FOREMAN OF MECHANICS to superintend boilers, engines, mill gearing, &c., Pristolee New Mills, Farnworth, near Manchester.

DESIGNS FOR SCHOOL BUILDINGS.—Premium of £25 for the most approved design for school buildings, &c., for the accommodation of 300 children, with master and mistresses' residence. Particulars of Mr. J. H. Cox, 17 Victoria-road, Old Charlton, S.C.

MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 6, 1859.

ENGINES AND ENGINEERS IN HER MAJESTY'S NAVY.

THE Report of Admiral Ramsay and Messrs. Nasmyth and Ward, although an extremely weak solution of useful information, necessarily opens up questions of very great importance in themselves—questions which we cannot pass over silently. These we must take up week by week, as opportunities may serve, with the desire of stating the views of the Committee and the replies of the Surveyor of the Navy as fully as may be desirable, and as fairly as may be possible. Our own comments will be offered only when they appear necessary, and then without any partiality save love of truth and fairness.

At the outset of their report the committee state they are desirous of expressing an opinion on the great importance of having all the documents which relate to the steam navy, and which are kept in the steam department of the Admiralty, in a state as accessible as possible for constant and ready reference; and further, that all the information necessary for an immediate comparison of the performances of the different vessels and their engines with one another, should be rendered practically available for immediate consultation. "The "committee conceive that this would supply a "sure method of judging of the efficiency of en- "gines employed; and when it is considered "how large are the sums annually expended upon "engines, they conceive that a full and accurate "knowledge of results produced, by the sums "thus expended, must be a check upon extra- "vagance." They say they have met with the greatest difficulty in investigating particular subjects, and found "a want of clear method "and classification in following the details "through the various books and records where "the information is to be found." They then direct attention to the quarterly returns of the performances of steam-vessels and their engines. It is proper first to explain that it was resolved by the committee to take specimens of different classes of steam men-of-war, propelled by the screw, the engines of which were made by different makers, to put them into a tabulated form, and thus institute a complete investigation of their comparative performances. To fill up this tabulated list of steam-ships, it was necessary for ascertaining some points to have recourse to the steam quarterly returns, and the documents belonging to each ship had to be examined separately. "But unfortunately," say they, "probably under the impression that little "use would be made of these returns, they "proved to be extremely imperfect. For in- "stance, in many cases, that most important "point, the number of miles obtained from a "ton of coals, is not inserted; and in too many "of the entries it is evident that little reliance "can be placed upon the accuracy of different "items in details." The committee are convinced that the beneficial effects upon a knowledge of steam engineering would be considerable if some intelligent person was appointed to examine these returns, to report when there were any important omissions, and to register with regularity and precision the most essential particulars. In order, therefore, to improve the mode at present adopted in the steam department of the Admiralty of tabulating the expenses and performances of steam-vessels, the committee considered several plans, and finally recommended that one suggested by Mr. Munday (their secretary) should be adopted. To carry out these arrangements they propose certain changes, of which the chief are, "that for "each steam-vessel in Her Majesty's service, a "separate book should be kept at the Surveyor's "office attached to the Admiralty;" and "that "a naval officer of long experience in steam- "vessels, accustomed to making calculations, "should be attached to the steam department of "the Surveyor's office, to keep up the book as "proposed, entering therein from the quarterly "reports the various items."

To all this the Surveyor replies that money accounts, properly so called, are not kept, and were never intended to be kept, in the Surveyors's department, except as far as may be necessary for conducting the business of the office and for furnishing the Board with such general information as they may call for: that no intimation was given by the committee implying that their object was, not only to ascertain facts, but to suggest improvements in the method of keeping the accounts and records and of tabulating their contents; and that if such an intimation had been given, the committee would have seen that some of their ideas had been anticipated, for from certain returns abstracts were made and recorded of the distance steamed by every ship in the navy, and of the coals expended, while for every large ship a separate book was kept, in which to record such particulars of her machinery and its working as it seemed desirable to keep together; and to ensure greater accuracy and completeness of returns from ships, the Board had been frequently moved to call the attention of commanders-in-chief and others to instances of comparatively great neglect and error in filling them up.

"To cause, however," says the Surveyor, "all returns from ships, such as those referred to by the committee, to be filled up on technical and scientific points in a perfectly reliable manner, would, it is well-known to persons experienced in such matters, be an utter impossibility, nor would the attempt, attended as it must be with correspondence without, be tolerated by any Board, unless the object was more important than it is. Such returns generally answer the principal ends for which they were framed,—periodical statements of the condition and working of machinery and boilers for the information and guidance of the department, and permanent records, to be referred to at all times like the logs of a ship; but, as was before stated, the most important matters are extracted, and recorded so as to be readily available. Looking, however, at the committee's recommendations, there is no objection to the above suggestions, or to adding to the present quarterly reports additional columns to contain all the information which the committee propose to collect. . . . . The additional labour thus entailed would not be such as to render necessary any increase in the establishment."

In our judgment the foregoing remarks, both of the committee and of the Surveyor, betray an insensibility to the great benefits which might be conferred upon science by a fuller observation and registration of the facts which our steam navy might easily be made to furnish. But as this is a subject which is but very lightly touched upon in the report before us, we shall not here drag it into prominence. It should be remarked, however, that the great suggestion of the committee on these documents appears to be the introduction of a model quarterly return, which is to show, in a tabular form, the efficiency of the machinery by the number of miles run since defects were last made good, and all particulars necessary for enabling the officers who had the responsibility of repairing the engines to form a judgment of the wear on the bearings and other parts. Now, we should like to know what practical engineer would like to form an opinion of the repairs necessary from such data? Such a document might be useful as a means of judging or determining the efficiency of different engines by comparing their actual condition with one another and the work performed. But the obvious inference from the report is, that the wear on the bearings and working parts of engines will always be in some known relation to the number of miles the vessel has run, whatever be the form or quality of the materials employed, or the size and shape of the body propelled, and whatever the skill and care of the engineer in charge may be. If any relation independent of all these conditions exists, the committee are, no doubt, the discoverers; no one else has ever suspected it. The present practice may not be perfect, but it certainly looks much more reasonable than the improvement proposed. When a vessel comes into port from a foreign station the engineer in charge makes out a list of defects known to himself, which list is forwarded through the captain of the steam ordinary to the inspector of machinery afloat, who, being a professional officer, ascertains by actual examination whether these defects require to be made good, and reports to the Admiralty accordingly; and it not unfrequently happens that the Surveyor of the Navy refers this report to the factory officers for further examination and professional report. What is there in all this to disapprove of? It is not a little singular, in connection with this subject, that the secretary of this committee is not only permitted to submit a plan for these tabulated records, but that it is recommended by them to the Admiralty in preference to a more comprehensive plan by some one else. The committee also propose that "an intelligent naval officer" be added to the steam department for making these tabulated records, altogether overlooking the fact that there are already, in the Surveyor's own department, and under his control, men most competent for the purpose, both theoretically and practically.

In the next subject treated by the committee—the care and preservation of the steam-engines and boilers on board Her Majesty's ships—we are plunged into that very interesting and important question of the condition of the Engineers of the Royal Navy. As a preliminary observation, the committee record that upon inquiries being made, it appears that, with a few exceptions, the machinery of our steam men-of-war employed on foreign stations has generally been kept in good order.

"This fact is an abundant proof, and perhaps the only satisfactory proof that could be adduced, of the strict attention which must generally have been paid on board these vessels after they left home by the chief engineers, and those placed immediately under them. And this fact has at the present time suggested that the committee should now record their opinion, that the efficiency of the engines on board men-of-war must mainly depend upon the skill, industry, and zeal of the chief engineers. In further support of that view, the committee would strongly urge, that all instances of wilful neglect should meet with certain punishment; but they would at the same time as strongly urge, that proper means should be adopted for fostering and encouraging that zeal and energy which never ought to be allowed to die away. That engineers in charge of steam-engines should not be removed from one ship to another, except under peculiar circumstances, has been much urged upon the committee. It must be admitted, however, there are many difficulties in the naval service, which will prevent the same chief engineer from remaining permanently attached to the same ship. One of these difficulties has lately been removed by the equalization of the pay of engineers, irrespective of the classes to which they formerly would have belonged. And, on the whole, the committee would rather direct attention to the subject, than advise a positive rule, although they do recommend that changes should not be made, as had heretofore sometimes been done, to all appearance, on very slight grounds."

In his reply to these remarks the Surveyor

Digitized by Google

says the committee justly state that no rule can be laid down on this subject. "Had the committee referred to any individual change, doubtless ample reasons could be given for it; this, however, had not been done, and therefore no specific reply can be made; but it is evident that the large number of chief engineers required for the screw ships built and converted within the last few years could only be obtained from our paddle-wheel vessels: hence arose the necessity for many of the removals." Due regard must also be had, he says, to their qualifications, to the length of their sea-service, and to the reasonable expectations of being appointed to larger ships, which is unquestionably looked upon by them as one of the rewards for long and meritorious services. The committee in making the statement that "changes should not be made, as had heretofore sometimes been done, to all appearance, on very slight grounds," refer to page 26 of their minutes of proceedings; "not one word, however, is here or elsewhere to be found," says the Surveyor, "to justify such an imputation."

"This is another example of imputations being made without a shadow of evidence. Indeed, the committee did not apply to the only source from which authentic information could be obtained, viz., the department of the Surveyor, notwithstanding they were expressly directed to do so by their instructions; and for anything which appears, they applied nowhere else. They refer, as before remarked, for proof to a part of their proceedings which has no reference whatever to the subject. Nearly the same observations apply to the very obvious recommendation of the committee, 'That a regular system of reward and promotion for zealous and diligent engineers, of reprimand and warning for the underserving, should at once be adopted and made known to the service.' It must be assumed that their reason for thus laying down the principle upon which rewards and punishments should be distributed was an impression on their minds that in some cases it had been departed from. No instance can be pointed out in which a complaint against an engineer has been improperly disregarded, or of superior merit being overlooked."

In connection with this subject we may remark that it would not be unreasonable to expect, after the great expense the country has been put to in visiting the various steam ordinaries, and in trying the numerous vessels' engines mentioned in the report, that some suggestions should have been made under this head as to the best means of preserving the valuable machinery on board ships in ordinary. But not a single idea do we find, nor a hint of any kind in reference to this most important matter. The whole thing seems to be ignored by them:—"It is not expedient that they should enter into minute detail as to the best means of preserving engines and boilers laid up in vessels in ordinary;" they would rather advise "a full confidence in the captains and engineers of steam reserves at the different ports." We do not dispute for a moment the soundness of this advice, but we do very much question whether it is worth the price the country has paid for it.

The committee next recommend that deserving assistant-engineers should be promoted, and that such promotion should be so made as to prevent the natural wish for advancement being too long delayed; and the committee believe the number of assistant-engineers might with advantage be diminished, and the place of a portion of the promoted engineers be supplied by a superior class of stokers, in order that by decreasing the number of assistant-engineers, promotion to a higher grade may be rendered more rapid. They further state that several are admitted as engineers into the navy who are practically of little service when any repairs of engines are required; and that this deficiency in a part of our assistant-engineers might in future be obviated by requiring from all candidates for admission, not only general certificates of their having been artificers, but further certificates of their having actually worked so long in a Government factory as to test their abilities.

The Surveyor admits the importance of the subject renders this suggestion worthy of consideration. The main question is, he says, are the existing regulations under which engineers are admitted into the Royal Navy practically sufficient to answer their intended purpose? And, he adds, it will be seen from the following statement that they are clear and somewhat stringent:—

"Every candidate must produce satisfactory certificates from the manufacturers in whose factories they have worked of their practical skill.

"Also of good conduct.

"He must pass a satisfactory examination before the chief engineer of Woolwich, Portsmouth, or Devonport Dockyard, who either rejects the candidate at once, or certifies him to be fit for entry; and the passing certificate of examination is marked as 'ordinary,' 'creditable,' or 'highly creditable,' and shows where he has been employed, and other particulars.

"These examinations are kept up to the highest point which the varying pressure for additional engineers renders practicable.

"He is also examined by a medical officer as to his bodily fitness for entry.

"The successful candidate is not then entered for permanent service; he has to pass at least one year on probation; and no engineer on probation is ever made an assistant-engineer, even of the third-class, until he is recommended for that rank by the commanding officer under whom he may be serving."

That the regulations work satisfactorily is proved, he says, by the three-monthly reports from all steam-ships and vessels, on the qualifications, character, and conduct of the engineers: some exceptions of course occur: in such cases, the individual is discharged or reprimanded, according to the nature of the report. Under these circumstances, the suggestion of the committee does not appear to him calculated to realise much benefit. If it did, the inconvenience and expense of applying a factory-test—for the young men must of course be paid—ought not for a moment to be regarded. But that these would not be inconsiderable will be evident when it is borne in mind that during the last six years no less than 2,101 candidates have offered themselves, and that 886 have been passed. The Surveyor further says it is not unreasonable to expect that the application of such a practical test might have the effect of deterring many modest and promising young men from offering themselves as candidates. In explanation of this view he says:—

"A rejection under the present system is doubtless accounted for by the candidate to his friends as the result of his being unable to perform some difficult arithmetical operation, or in some other way which in their estimation does not humiliate him; but a rejection, after he had complied with all other conditions, upon a practical, and it may almost be called a public test, on the ground of a want of ability in his own art, would be far more serious to him, and give rise to a feeling of greater dissatisfaction; a result which it is obvious ought to be avoided unless some important object is thereby gained. But it may be said that few would be thus rejected, and those few would be persons whom it would not be desirable to enter. This, it is apprehended, is not the true view of the case. At present, if a candidate presents himself with unsatisfactory testimonials, he is told he must obtain better; if he can do so, he presents himself again; if not, there is an end; he is excluded. But if testimonials were no longer the admitted and sole proof of practical fitness, and the examining officer were authorised to employ him in the factory to ascertain the fact, he could not, morally speaking, hesitate to grant the appeal of the candidate for a practical test; and thus the number rejected by this process would be far from inconsiderable, which alone would outweigh any benefits which could possibly result."

The Surveyor further informs us that at this moment there are in the three steam ordinaries 192 assistant-engineers; and the inspectors of machinery afloat have recently been ordered to report if they have discovered any of them to be inefficient workmen. One only has been reported, and this person is on probation. One assistant-engineer, who was formerly at Sheerness, is also reported against; and three who were formerly at Portsmouth, two of whom have been discharged from the service; seven formerly at Devonport, but now on board various ships, are also reported against; but all these, with one exception, are on probation. "It will thus be seen," he says, "that there are only very slight grounds for the recommendation of the committee to send hundreds of candidates through our factories every year to be tested, but none whatever for entrusting the duties hitherto performed by engineers to a very inferior class of men, namely, stokers. For even supposing the service now suffers, as seems to be implied by the committee, in consequence of the inefficiency of engineers, how this is to be remedied by the employment of stokers in their room the committee do not explain."

Upon the general question at issue here—the advisability of supplying the place of certain engineers with stokers—we do not feel competent, at present, to offer an opinion. There is certainly much to be said in favour of both views. On the committee's side it is apparent enough that the handiwork and drudgery which the assistant-engineers have to perform in keeping the engines in good order is of such a nature that its transfer to stokers would tend greatly to improve the position of the engineers. But then it cannot be doubted that the effect of the change would be to dissociate engineers from their most important duties, and lift them away from those very operations which it is their express function to carry out. On the other hand, we think the Surveyor's assertion that the present system works satisfactorily is not to be relied upon; nor are the reasons which he assigns for it. It is all very well, from an official point of view, to say that the "official" reports of commanding officers afford but little ground for dissatisfaction with the class of engineers lately brought into the service. And the same remark applies to what is said of the stringency of the existing regulations under which engineers are admitted into the navy. But it is useless to shut one's eyes to manifest facts. Many young men of a thoroughly inferior class *have been* entered, and *are* retained in the service, as every one intimately acquainted with the navy knows; and some remedy should be found for this evil. All we can affirm is, that either the present regulations are not stringent enough, or else they are not carried out faithfully. On the other hand, it should be remarked that (as the Surveyor states further on) there have been times when all efforts and expedients have failed in providing a sufficient number of engineers to meet all the demands of the service. This, however, seems to point to the necessity of adopting more efficient means than the present of training a sufficient supply of men for the service. There ought to be no difficulty in doing this now the want is understood.

It must, however, after all be remembered, say the committee, that much of the care and preservation of the machinery must still rest with the commander of the vessel; he ought to be constant in his duty, inspecting the engine-room, and giving encouragement and direction to those belonging to that department. The commander can also preserve the engines and boilers by sparing all unnecessary use of them. On board men-of-war, in a great variety of cases, the length of a passage is of little moment. In these cases let the sails alone be

Digitized by Google

used; but of course, in all other cases, when it is of importance that the voyage should not be protracted beyond a certain time, then a judicious conjoined employment of steam and sail is of consequence; and it is at such times especially that the commander who has carefully studied the subject has an opportunity of turning his knowledge to advantage. The committee are anxious to direct attention to this subject; they are aware, they say, that in itself it is plain, and, indeed, simple, but still they are convinced it is often misunderstood; and they are further induced to notice this matter from observing, that one of the best practical books on the marine steam-engine which is supplied to the navy, and which lays down the right principles involved in this question, yet gives an account of a voyage intended to show the advantage of using the sails and steam combined, and although attention is drawn to the small quantity of coal thereby consumed, yet, upon examination, there can be no doubt that the vessel would often have gone faster if the steam had not been used at all, and in such cases there would have been a saving of the whole of the coals.

"The principles involved are as follows: with a fair wind, the number of miles obtained from a ton of coals is the number of miles that the engines increased the speed of the vessel above that which she would have gone with sails alone; that is to say, suppose a steam-ship goes nine knots, with a fair wind, under sail alone, steam is applied, and the ship goes ten knots; the consumption of coal is, say, two tons per hour, then 0·5 knot is obtained from each ton of coal. But now, under the same circumstances, suppose that a comparatively small amount of steam is applied, then it will follow that, unless a sufficiency of coal is used to keep up the revolutions of the screw to a speed equal to what would be the rate of the ship under sail alone, the way of the ship is less under sail and this small supply of coal than it would have been under sail alone; in short, the coal used in such a case would only retard the ship: and from this it may be deduced, that although fore and aft sails, and in light winds, when the wind is not too far aft, square sails also, with the steam, may often be useful, and save coal; so that when the object is to make quick and economical passages, steam and sail ought certainly to be combined; still it is advisable that steam and sail be generally used separately. This is given only as an illustration how necessary it is for the naval officer, not only to have some knowledge of the agency of steam, but also a kind of knowledge not generally acquired by the engineer."

On this the Surveyor, somewhat archly, we fancy, remarks that it no doubt is highly important that all naval officers should be well acquainted with the principles of steam navigation, and a sound knowledge of them is doubtless fast spreading; "it may well be "doubted, however, how far the committee "have laid down principles which would bear "the test of examination, but it would be out of "place to discuss them here, as they are in-"tended only as illustrations to show the ad-"vantage of officers possessing a knowledge of "sailing and steaming, which is questioned by "no one." On a future occasion we shall take further notice of the doubt which the Surveyor here casts upon the scientific soundness of the committee, and show what ground he has for casting it. But we must stop here for the present.

THE IMPROVEMENT OF OUR COINAGE.

PURSUING the important question of introducing into this country a system of coinage on the decimal principle, we have now to offer some further remarks on the unsatisfactory state of the existing metallic currency—especially the copper portion of it—and the causes which have led to its deterioration. There are at present circulating in the British islands, and making up the aggregate quantities given in our last week's impression, four distinct kinds of pence, with their satellite halfpence or farthings. In the first place there are the heavy pieces, popularly known from the broad band surrounding both obverse and reverse as "ring" pence. Of these, which were struck at the old Soho Mint by Messrs. Boulton and Watt, between the years 1797-1799, 16 go to the lb. avoirdupois, and they have certainly worn remarkably well, although they must have worn out a vast number of pockets in the sixty years of their existence. At the close of 1799, pence, halfpence, and farthings of respectively 18, 36, and 72 to the lb. were struck by the same firm, and these circulated alone with their weightier brethren until 1805, when a further improvement, as it was deemed, took place. In that year, 24 pence, 48 halfpence, and 96 farthings to the lb. weight were considered fair proportions for the copper coinage, and new dies having been got up for the purpose, Boulton and Watt again set to work in producing these comparatively light coins. It will be seen thus that within a space of eight years three kinds of inferior coins were stamped into vitality and became current. This was not, however, considered sufficient, and an Irish coinage of great extent, and in which the 1 lb. weight was divided into 26, 52, and 104 pence, halfpence, and farthings respectively, took place in 1806, and continued to go on simultaneously with the last-named English variety up to 1823. In that year the Irish coinage was abandoned, and although there have been distinctive copper tokens struck since for the Isle of Man and for the States of Jersey, of like proportions to those for Ireland, yet it may be said that the arrangement of 24 pence, 48 halfpence, and 96 farthings to the lb. weight has prevailed throughout Great Britain ever since 1823, and is that of the present day.

It will be admitted from this record of facts in connexion with the copper coinage that there is a sufficient medley of recognised and legal pieces of money in circulation among us; but there is in addition to these, as most people know to their cost, a very large per centage of non-recognised and illegal discs of copper, of which the public can "make neither head nor "tail," and which are altogether discreditable to an enlightened community. Is it not high time then, we ask, that, whether the decimal system be adopted or not, the whole confused jumble of copper coins, nearly six thousand tons in weight, should be sent once more into the foundry, there to be united with some more spiritual, or at least more valuable metal, and then re-issued in a uniform and handsome shape?

By judicious combinations of metals, lightness, beauty, and value may be attained; and these are the desiderata for a new coinage. In the United States' Mint experimental pieces have been issued of nickel and copper. How these will stand wear, time will reveal, but their dull grey colour is not pleasing to the eye, and they are of dumpy form—too thick for their small diameters. The bronze coins of the Napoleon III. and those of the Victoria Canada Mintages are, indeed, models in this last respect. For ourselves, we believe that the new clay metal, aluminium, which promises to revolutionise in other respects the world of metals, will be found a most excellent material for admixture with copper for the purpose in question. It is true that its properties are not yet fully developed, but enough is known to augur for aluminium a brilliant and useful future. Melted with copper in different proportions, any shade of colour between those of zinc and fine gold may be obtained, and we look forward to the day when Dr. Graham of the Mint, or some of his scientific *confrères*, shall arrive, by experiment or otherwise, at an amalgamation of aluminium and copper, from which may be cast a new coinage—decimal or duodecimal—that, with the aid of the engraver's art, and the skill of the machinist, shall surpass, in proportions, colour, and practical utility, the coinage of every other country. This matter has been dwelt upon at some length because it is right that the public should comprehend it thoroughly, and be thus enabled to bring the force of their opinion to bear upon the Government in effecting a wholesome and necessary reform. Mr. Disraeli professes to bow to public opinion, and declares that it is the most potent of all agencies. If we can enlist it, therefore, in behalf of a decimal coinage, the good work in introducing it may be said to be begun.

SUBMARINE TELEGRAPH CABLES.

WE have heard much lately of the substitution of india-rubber for gutta percha in the insulation of the wires of electric telegraph cables. Messrs. Silver and Co., of North Woolwich, have made themselves very prominent in connection with this matter, and by virtue of a wide-spread invitation to their works, and to a liberal feast afterwards, obtained very flattering notices of their experiments in almost all journals but our own. We fear, however—judging from the specimens of Messrs. Silver's cable which have been shown to us—the practice of submarine electric telegraphy has but little to expect from that quarter. We did not attend the experiments at North Woolwich, although invited; we could not make it convenient to attend them; but specimens of the Silver cable have, as we have intimated, reached us from various sources, and they really appear to us to be of a most unpromising character. The comparatively untenaceous substance with which the wire is coated can only have produced insulation with the kindliest electricity. That it would stand the wear and tear to which a long line of submarine cable is likely to be subjected, even in the laying, we do not for a moment believe. We write this without the least shade of antagonism to Messrs. Silver, whom, for many reasons, we very much respect; a simple desire to express what we cannot but think, is the only motive that prompts these observations. If the fact be, as we believe, we do not blame Messrs. Silver either for their experimental exertions in the matter, or for their endeavours to give all possible publicity to what they doubtless believed to be a valuable improvement. On the contrary, we regret that their good intentions have resulted in no better success. The failure is to be attributed, not to themselves, nor to the newspaper reporters who did so much for them in the way of eulogium; but to those laws of nature which often stubbornly resist even the sturdiest endeavours of individuals, and the liveliest efforts of gentlemen of the press—however liberally the one may be feasted by the other.

That india-rubber may, and will, under some circumstances, supersede gutta percha seems, however, exceedingly probable. We believe, moreover, that the means of applying it efficiently for the purpose have been fully attained in the invention described and illustrated on another page of this number. The inventors—Messrs. Hall and Wells, the well-known manufacturers of elastic fabrics—have had very great experience in the manipulation of india-rubber, and appear to have brought all that experience, with its corresponding skill, to bear upon this matter in the invention before us. In the construction of the apparatus to be used in the actual manufacture of cables of great length, they have further availed themselves of the

Digitized by Google

ability of Messrs. Easton and Amos, the celebrated engineers, at whose works they have a very large machine nearly completed. Their method of forming the cable may be briefly stated as follows:—They commence by covering the conducting wires with a spiral layer of grey or unbleached cotton, as being the most pure. They then cover the cotton with strips of rubber cut from the bottle or other form in which it is imported, without being masticated or otherwise operated upon, laying on the strips spirally, and with overlap. This employment of "pure" rubber for the first coating of the wire is a very important point, and evinces the practical knowledge of the inventors. They then wind round outside of the spiral layers of rubber a thread of vulcanised rubber covered with cotton. The effect of this elastic thread is most remarkable. Being always in tension, owing to its elasticity, it so effectually compresses the layers of pure rubber beneath it as to firmly consolidate them into one substance, incapable of being again separated without great difficulty, and sometimes not at all. They perform all the coverings at one operation, and employ for the purpose a spiral covering machine to lay on the several coverings in the order above described. In some cases, in place of the covered thread of vulcanised rubber before mentioned, or in addition thereto, they apply further spirally-laid coverings of pure rubber laid on alternately in opposite directions, and envelope the whole in a similar covering of vulcanised rubber or not as may be desired. The whole of these operations may be performed in one machine. Having thus effectually insulated the wires, they further protect them by applying a coating of gutta percha of the ordinary kind, where that may be found desirable, and surround this gutta percha with plain hemp (free from oil, tar, and grease) braided on. Where gutta percha is not used, the plain fibre is laid immediately upon the insulating material. Then they braid or wrap on a coating of spun yarn saturated with tar or other preserving substance. The spun or tarred yarn or wrapping of rubber is then protected by wires laid on by means of a cleverly-arranged hollow-tube braiding machine at one operation, whereby one set of wires is laid longitudinally without any twist, while another set forms the braiding, and encloses the longitudinal wires. The advantage in using a braiding machine of their construction for covering telegraphic cables is beyond dispute, as by means of it cables can he made of any strength required, and of almost any required lightness, and at the same time be free from twist, and have all the strain taken off the conducting wires during the paying out of the same into a deep sea. It appears, also, that scarcely any strain whatever is brought upon the core during the application of the external iron covering, which is by no means the case in cables covered with spiral wires. In them the core is subjected to a very great strain, and the insulation is thereby seriously damaged. The inventors, of course, lay no claim to the use of india-rubber for the insulation of telegraph wires, but limit their claims to the improved methods and means of applying it.

Specimens of cables manufactured by Messrs. Hall and Wells have been submitted to us, and we say, with no kind of hesitation, that the insulation of the wires of the same is as good as it is possible for it to be—and that is much more than we can say of many specimens that come before us. Nor is the insulation only good; the cable is also light, very strong, very elastic, and very little liable to derangement of any kind during the handling of it, either in shipping it or in paying it out. We shall not urge its merits upon telegraphic engineers and companies, as they must win for it a speedy and extensive adoption. What its cost may prove to be we do not know; but, other things being as we have stated, the cost of it is a matter of minor importance.

THE NEW IRON STEAMSHIPS FOR THE NAVY.

At a discussion which took place at the Society of Arts, on Wednesday evening (May 3), after the reading of a lecture by Mr. Leonard Wray, on timber for ship-building, Mr. E. J. Reed, one of the Editors of the Mechanics' Magazine, (whose paper on the ships of the Navy recently excited much attention) made the following remarks:—"However unfit the iron ships which have hitherto been constructed for war purposes may have proved, we are undoubtedly about to return to the use of iron in the construction of such vessels. It will be in the recollection of the gentlemen present that nine or ten weeks ago Sir John Pakington announced in the House of Commons that, whatever may be their cost, we had no option but to commence the construction of iron-coated vessels. The reason alleged by him for this was twofold; in the first place, he said, the experiments made with Sir William Armstrong's gun had shown that thick iron might be employed with advantage as a defence for the sides of ships; and in the second place, that the French had two ships thus defended fast approaching completion. Since that speech of Sir John Pakington's was made, we have received a report made to the Treasury in January last, from which I draw the authority to state that the French were then actually preparing four of these iron-sided vessels. These vessels, it is stated, are to be substituted for line-of-battle ships. Their timbers (for they are built of wood) are of the scantling of a three-decker. They are to carry 36 heavy guns, most of them rifled 50-pounders, which will throw an 80-lb percussion shell. We are told in the report that the naval men of France seem to be so convinced of the irresistible qualities of these ships that they are of opinion that no more ships of the line will be laid down, and that in ten years that class of vessels will have become obsolete. We have still further information to the effect, that no less than eight of the ships are in contemplation by the French Emperor, the construction of six of them being fully determined upon. These vessels will not prove very efficient ships in many respects. With engines of 900 horse power only, they cannot be very fast; nor can they be expected to prove very handy. But the important fact to be observed with reference to them is, that they may fairly be expected to prove proof to both Paixhans and Armstrong shells, and you may judge for yourselves what would be the effect of half-a-dozen shell-proof frigates making their appearance among a fleet of our wooden ships. In order to avert such a disaster as this Sir John Pakington obtained a grant of money from the House of Commons to enable him to build a few shot-proof ships for our own Navy, and called upon private ship-building firms, and also upon his own master shipwrights, to furnish designs for such vessels. As soon as these designs were received, if not before, it became perfectly evident that the most efficient method of constructing the shot-proof frigates would be to build them wholly of iron. This has been fully decided upon. I believe the main reason of this is to be found in the fact that it is not practicable to cover the whole of the exposed portion of the ship with thick iron, on account of the weight, and it would not, of course, do, in these days of explosive shells and liquid fires, to leave any portion of a wooden ship exposed. Consequently, the resort to iron alone became absolutely necessary. That the uncoated portion of the ship will be open to what the lecturer of the evening has denominated the 'disastrous liabilities of a thin iron structure' is most certain; but the difficulty is got over by so proportioning the volumes of the defended and undefended portions of the vessel that, should the latter become riddled by shot, and water-logged, the vessel would still be sufficiently buoyant to float, and maintain the action in which she happened to be engaged. I am very sorry to say the Admiralty have lost time in proceeding with this great and most necessary undertaking. Sir John Pakington promised the House of Commons that he would not lose a moment in bringing these ships into existence. But two months and more have passed since then, and yet no contract for building a single iron coated ship has yet been issued. I fear we must impute to the extravagantly imaginative speech of Lord Clarence Paget a part of this delay, for the Admiralty departments have had much to do in the way of vindicating themselves from his unmerited attack. It takes much time to go over the ten years' accounts of such a department as the Admiralty. Still for my part, I think delay on such grounds is scarcely justifiable. It would be better for such a speech as Lord Paget's to go unanswered altogether, than to withdraw our strength for months from an undertaking by which alone we can maintain an equality with France. In the hope that my words may find their way into the public papers, and thus reach the eyes of our Government, I bring this subject to your attention. It appears to me scarcely fair to this great iron-ship-building country to allow it to fall behind France in this matter."

Proceedings of Societies.

UNITED SERVICE INSTITUTION.

April 29.—General Portlock delivered a lecture in the theatre of the above institution "On the Advantage of cultivating the Natural and Experimental Sciences, as promoting the social comfort and practical utility of Military Men," before a numerous audience, among whom were Sir William Gomm, K.C.B., Generals Cameron and Drummond, and other distinguished visitors. In the course of the lecture General Portlock spoke of the ill consequences of adhering to the narrow view adopted by many, of considering every branch of knowledge useless which cannot be shown to have a direct practical bearing either in the production of wealth or in the special business of a profession. It is impossible, he observed, to lay down as a rule that any knowledge once acquired may not prove the means in after life of overcoming difficulties otherwise insurmountable, but further than that, education must always be considered as not only intended to supply the knowledge actually required in the prosecution of some definite profession, but also to supply the mind with a wholesome nutriment which should keep it from preying on the body.

INSTITUTION OF ENGINEERS IN SCOTLAND.

April 28.—The anniversary dinner took place in the Queen's Hotel, George square; Dr. W. J. Macquorn Rankine, President, in the chair, and Walter Neilson, Esq., President elect, acting as croupier.

The Chairman, in proposing the Army and Navy, referred to the fact that in former times there existed no distinction between military and civil engineering, both branches being practised by the same individuals. It was worth remarking that the great military commanders of antiquity were engineers—a circumstance to which, in a great measure, their success and skill as soldiers was owing. Julius Cæsar was a consummate engineer, as would be seen from his "Commentaries," a great portion of which he devoted to the description of the engineering works erected by himself. Leonardo da Vinci was a skilful engineer, as also was Michael Angelo, and Benvenuto Cellini was a military engineer of the highest merit. In modern times, however, owing to the division of labour, and to the cultivation of the arts of peace, civil and military engineering were generally regarded as distinct professions, but there was, nevertheless, a strong connection between them; and he was glad to see that recently the intimacy between both was beginning to be recognised again. Civil and mechanical engineers of the highest eminence had lately conferred the greatest benefit upon the military art by their improvement of implements of war, such as those introduced by Whitworth and Sir W. Armstrong, which had brought the art to a degree of perfection never attained before. For this reason civil and mechanical engineers should look upon those who professed the

Digitized by Google

military art with interest and sympathy. Then as regards the navy, he need scarcely remind them of their intimate connection with that branch of the service, since they must all be aware that the success of our fleets must depend on the construction of swift and strong ships, and the machinery for their propulsion.

THE SOUTH WALES INSTITUTE OF ENGINEERS.

April 26.—The third annual meeting was held in Newport last Tuesday, under the presidency of Ebenezer Rogers, Esq., F.G.S., &c. There were present a considerable number of scientific gentlemen engaged in the various industries of the district. The Mayor of Newport and other gentlemen of the town were also present as visitors. By a regulation of the institute we are unable to give a report of the proceedings; but we learn from the *Star of Gwent* that the discussion chiefly turned on the combustion of coal, in the course of which the comparative values of English and Welsh coals were discussed—the opinion of the members being adverse to the merits of English coal for steam purposes. A paper by Mr. Wilson, of Sheffield, on Steel Manufacture brought out the fact that the trade had been materially stimulated by the demand for crinoline hoops. The discussion of this paper was postponed to the next meeting. A paper by Mr. Murphy, of Newport, on Railway Wheels was also postponed, on account of want of time for its reading and discussion. The dinner was held at the Westgate Hotel at half-past four o'clock. The chair was occupied by Ebenezer Rogers, Esq., F.G.S., president, supported by H. Sheppard, Esq., Mayor of Newport, Sir T. Phillips, F. Levick, Esq., Blaena, Warrington Smyth, Esq., &c. The vice-chair was filled by W. S. Clark, Esq., of Aberdare. About eighty gentlemen were present, including those who were not members of the institute, but who were interested in its welfare.

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY.

April 19.—W. Fairbairn, F.R.S., President, in the chair. The following gentlemen were elected members of the Society: As honorary members: W. J. Macquorn Rankine, LL.D., F.R.S., &c.; Baron Carl T. von Reichenbach. As ordinary members: T. Heelis, T. R. Wilkinson, A. Ransome, B.A., M.B., M.R.C.S. The annual report was then read by Dr. Schunck, one of the secretaries. In their report the council express their conviction, that at no period of its existence has the Society been in a more flourishing condition. It has been considered advisable to postpone the preparation of a new catalogue of the library until the result of a correspondence now in progress with a great number of scientific societies and institutions, for the purpose of introducing a mutual exchange of publications, shall be known, and the system of such exchanges shall thus have been more completely developed. The library is gradually emerging out of the insignificance in which it had remained until within the last few years. The improvement is almost entirely owing to the exchanges referred to; but an improvement on that basis, to whatever extent it be carried, can never bring the library to a desirable state of completeness. The transactions and other publications of learned societies and institutions, which are thus obtained, are undoubtedly of the greatest value, and of course absolutely necessary in a scientific library; but still, they constitute only one of its chief elements. Scientific periodicals and separately printed works—the other elements—must, as a rule, be bought. A project for supplying the necessary funds has been submitted to the council, and, if approved of, will no doubt be recommended to the attention of the members. After some remarks by Mr. Chadwick, the report was adopted on the proposal of Mr. Curtis, seconded by Dr. Clay. The annual election of officers then took place, when the following gentlemen were elected:—President: W. Fairbairn, F.R.S., Vice-Presidents: J. Prescott Joule, LL.D., F.R.S., F.C.S; T. Hopkins, M. Brit. Met. Soc.; Joseph Cheeseborough Dyer; Robert Angus Smith, Ph.D., F.R.S., F.C.S. Secretaries: Edward Schunck, Ph.D., F.R.S.; Richard Copley Christie, M.A. Treasurer: Henry Mere Ormerod. Librarian: Charles Fredrik Ekman. Of the Council: Rev. Wm. Gaskell, M.A.; Richard Roberts, M. Inst. C.E.; Joseph Baxendell, F.R.A.S.; Edward William Binney, F.R.S., F.G.S.; Peter Spence; Joseph Atkinson Ransome, M.R.C.S. Mr. Dyer moved, and Dr. Joule seconded, a vote of thanks to Mr. Ekman, the librarian, for the valuable services rendered by him to the Society. The meeting was then adjourned to Tuesday the 3rd of May.

SOCIETY OF ARTS.

May 4.—Mr Leonard Wray read a paper on Timber for Shipbuilding. A report of this lecture will appear in our next number.

MEETINGS FOR THE ENSUING WEEK.

MON.—*London Inst.*, "On Commercial Law," by G. W. Hastings, Esq., at 8 p.m.
Geographical Society—I., "Notes on the Lower Danube," by Major Stokes, R.E., communicated by Captain Collinson, R.N.; II., "Observations on the Geography of Central Africa," by James McQueen, Esq., F.R.G.S.; III., "Remarks on the Seychelles," by Lyon McLeod, Esq., F.R.G.S., at 8 30 p.m.

TUES.—*Royal Inst.*, "On the general facts and leading principles of Geological Science," by J. Morris, Esq., F.G.S., at 3 p.m.
Inst. Civil Engineers—I., Discussion upon Mr. Kingsbury's paper "On the Victoria Docks," and upon Mr. Harrison's paper "On the Tyne Docks;" II., "Short account of the Wrought-iron Girder Bridge over the Spey, on the Aberdeen and Montrose Railway," by Mr. W. Fairbairn, M.Inst. C.E.; III., "Description of the Government Water-works, Trafalgar-square, by Mr. C. E. Amos, M. Inst., at 8 p.m.
Zoological, at 9.

WED.—*Society of Arts*, "On the Recognition of Music among the Arts," by Mr. Henry F. Chorley, at 8 p.m.

THUR.—*Chemical*, at 8 p.m.
Society of Antiquaries at 8 p.m.
Royal Inst., "On the Seven periods of Art," by Henry Layard, Esq., at 3 p.m.
Linnean, at 8 p.m.

FRID.—*United Service Inst.*, "On the history of Gun-locks," by Mr. Robert Pritchett, at 3 p.m.
Royal Inst., "On the changes of terrestrial temperature at different geological epochs," by W. Hopkins, Esq., M.A., F.R.S.

SAT.—*Royal Inst.*, "On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

EXPLOSIONS AT GUNPOWDER WORKS.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—Every question has its "pro" as well as its "con," and the question of gunpowder works and their owners is no exception to the rule. In your last number are some rather severe strictures which I think need some reply. With the disgrace reflected upon chemical progress, I have now nothing to do, but I think I can prove that powder manufacturers are not quite so insensible to improvement as you seem to imagine. Has nothing been done (say during the last 25 years) towards improving the machinery necessary for the manufacture of gunpowder? Has no improvement been made in "Mixing-houses?" Has nothing been done towards improving the "Incorporating Mills?" Are the "Press-house," the "Caming-house," the "Drying-house," the "Dusting-house," what they were thirty years ago? These changes, I confess, are not blazed abroad to the world; but every one conversant (and very few are) with the manufacture of powder knows that the number of hands requisite in the houses is greatly diminished, and that the risk to which these are exposed is also greatly diminished. Surely you will not grudge the manufacturers their due meed of praise for these improvements—improvements the carrying out of which has cost large sums of money, but all has been cheerfully done where any good was likely to be attained. I cannot account for the lowness of wages given to men employed in powder works, and would fain hope there is some misinformation upon the matter; but I can say that *all* do not pay so badly as is represented. At the largest manufactory in England (perhaps in the world) the men employed in the more dangerous parts of the business earn weekly from 35s. to 44s., and with pride I acknowledge that a case of drunkenness is never known; and never does a man (and there is a great number) ever stay from work unless from sickness. Give men good wages and you may generally get good men. At the factory abovementioned not a fatal accident has occurred for more than twenty years. True, every care is taken both in the choice of men and machinery, but if, as is thought, these accidents are attributable to the state of the atmosphere, who shall cast censure upon the unfortunate manufacturer because he cannot cope with the elements?

Pray permit the subject to be fully discussed in your valuable journal, especially any information respecting the state of the atmosphere at the times of explosions. The lives of many depend upon this business, and if anything should be discovered by which these lives may be preserved, blessings will rest on the head of the discoverer. I am, &c.,

POLVORA.

THEORY OF NAVAL ARCHITECTURE.

No. VII.

IN the two preceding articles we have shown where ordinates should be drawn in a curvilinear figure, to give a tolerably correct approximation to the area. As the examples there taken are of the same character as ordinary midship sections, it will be seen to be necessary, when operating upon the draught of a ship, to place the ordinates closer in the neighbourhood of the keel, than in the other portions. Again, all ships, except those designed for high speeds, have the greatest amount of curvature in their horizontal sections at their extremities; consequently, when placing the ordinates to calculate the areas of these sections, it will be necessary to put them closer at the extremities than in the other parts.

We must now hasten to apply the rules to the calculations of the displacement of a ship, reserving all further discussion of the relation between the ordinates and areas until it is required from the nature of the calculations.

Our first example will be the simplest case which can be given, namely, a ship in which the constructed load-water line is parallel to the keel, and iron is the material of which she is composed. In this case the sections of the ship can be chosen so as to introduce no appendages which may not be safely neglected; the calculations will therefore be direct. The length of this ship between the perpendiculars is 156 feet; breadth extreme, 20 feet; depth, from the upper part of beam to lower part of the keel, 11 feet 6 inches; burthen, builders' measurement, 310 tons; draught of water forward and aft, 6 feet 6 inches; keel below the lower edge of rabbet, 6 inches.

Let Fig. 14 represent the sheer draught of a screw ship; *L WL*, the constructed load-water line; the length of the part *C D* between the stem and the foremost stern post is 151·2 feet. Divide *C D* into twelve equal portions of 12·6 feet each; through the points of division let vertical transverse sections be drawn; these are represented by the vertical straight lines 1, 2, 3, &c., and in order to meet the greater curvature, usual in ships at their extremities, let sections 1½, 2½, 11½, and 12½ be drawn parallel to these midway between 1 and 2, 2 and 3, 11 and 12, 12 and 13 respectively.

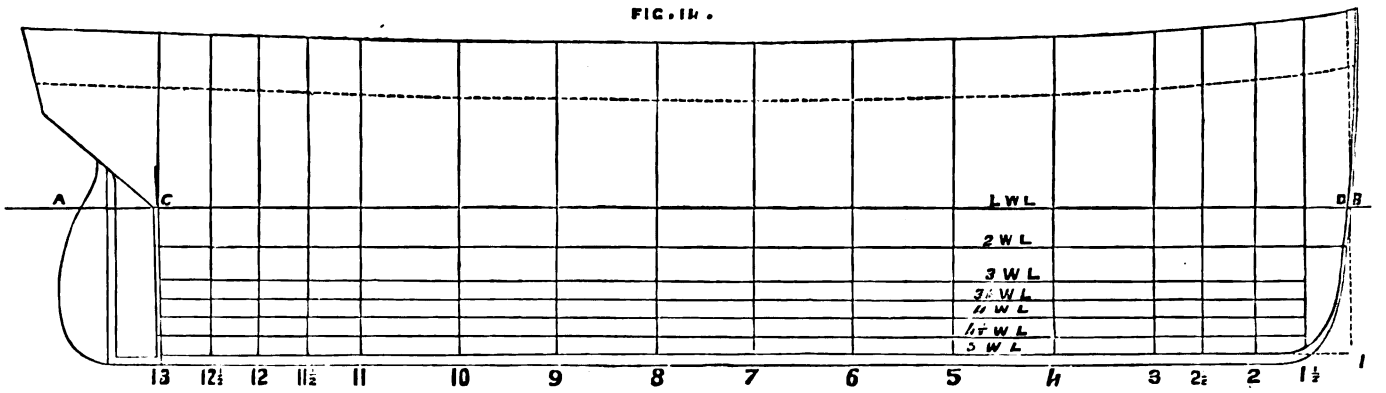
Again, the depth from the load-water section to the intersection of the side of the keel and the curved surface of the ship is 6 feet; let this depth be divided into four equal portions, each of which is 1·5 feet, and at the points of division let the water sections 2 *WL*, 3 *WL*, and 4 *WL*, be drawn parallel to the load-water section; and to meet the greater curvature in the neighbourhood of the keel let the sections 3¼ *WL*, and 4¼ *WL* be drawn parallel to these midway between 3 *WL* and 4 *WL*, and 4 *WL* and 5 *WL*, respectively. All these sections are represented in the sheer plan by horizontal lines.

The plane, *LWL*, of the load-water line—the transverse vertical plane through (1), the after part of the stem—and the plane through the middle line of ship, all at right angles to each other, are taken as the co-ordinate planes.

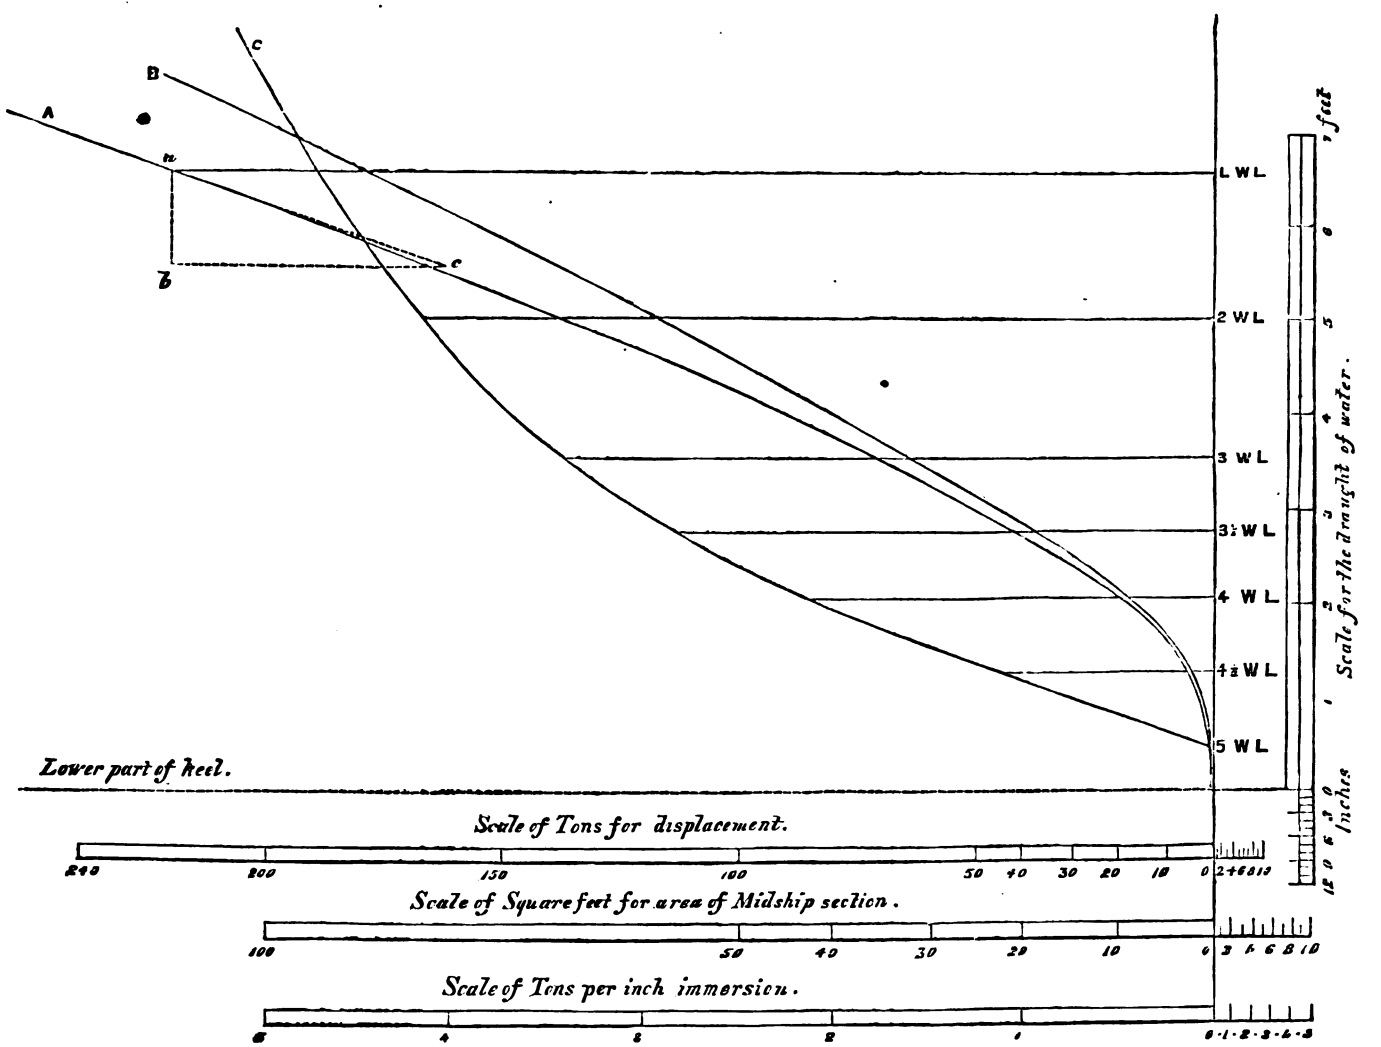
Now, it is evident that the transverse vertical planes intersect each of the horizontal or water sections, in lines perpendicular to the longitudinal plane through the middle of the ship, and therefore perpendicular to the middle line; consequently, the intersections of each horizontal section by the transverse sections may be regarded as ordinates to the curve in which that horizontal plane cuts the ship. Also since the vertical sections 1, 1½, 2, 2½, and 3; 13, 12½, 12, 11½, and 11, are drawn at 6·3 feet apart, the corresponding ordinates of the horizontal sections are 6·3 feet apart, and the number in each case is odd, therefore the area of these parts may be found by Rule 2. Also the ordinates between sections 3 and 11 are 12·6 feet apart, and the number is odd, therefore the whole area of any horizontal section may be found as has been already described.

Digitized by Google

FIG. 14.



SCALES: Of Displacement, *A*; Area of the Midship Section, *B*; and Tons per Inch Immersion, *C*.



Regarding any transverse vertical section in the same manner, it will be seen that the intersection of it by the horizontal sections may be regarded as ordinates to the curve; that the ordinates corresponding to the intersections of it by *L W L*, 2 *W L*, and 3 *W L*, are 1·5 feet apart; and those corresponding to those of 3, 3½, 4, 4½, and 5, are ·75 feet apart; in each of these cases the number of ordinates is odd, and the area of the entire transverse section may be obtained by the method described in our former articles. The load-water section being parallel to the keel, all the water sections are drawn in their true forms in the half-breadth plan, and their intersections by any transverse section are represented by a line perpendicular to the middle line; also the intersections of the transverse sections, and any water section in the body plan, are represented by a horizontal line, as explained in the articles on "Laying Off." The lengths of the ordinates may therefore be obtained from either the half breadth or the body plan.

Suppose these measured off for each separate transverse vertical section, the areas of these sections may be found as before described. If, again, these areas be regarded as the ordinates to a curve at the corresponding sections in the half-breadth plan, the area of the figure of which this curve is the boundary will represent the displacement.

Were we to proceed in this manner, nothing further would be required if our calculations were confined to a few ships; but if our examples were numerous, we should find it necessary to have recourse to some method by which the labor would be abridged, and the space occupied by the calculations be reduced. Various forms for this purpose have been adopted by Naval architects, and that which we give on the next page, now published for the first time, was devised by the late Mr. John Wilson, who was for many years the chief draughtsman in the Surveyor's department at the Admiralty.

It will be seen to contain the whole of the calculations relating to the displacement, as well as to the positions of the centre of buoyancy and

Digitized by Google

metacentre; all of which, for a ship of any class, may be placed on one page of ordinary paper. On the other side of the page are usually drawn the scales of displacement, area of the midship section, and sometimes that of the tons per inch immersion; so that on half a sheet of paper the whole of these important calculations may be registered.

The table will be found almost self-explanatory. In the upper line are written in order the horizontal sections, with vertical lines separating them; under them are written the numbers by which the corresponding ordinates of the transverse sections are to be multiplied to obtain the areas by Rule 2. In the extreme left column are written in order the transverse sections with horizontal lines separating them; and immediately to the right are written the numbers by which the corresponding ordinates of the horizontal sections are to be multiplied to obtain their areas.

These vertical and horizontal lines drawn on the table divide a portion of it into 17 × 7, or 119 compartments. Also since by the intersection of the horizontal and vertical planes 119 ordinates are obtained from the half-breadth or body plan, as before described, these may be respectively inserted in the corresponding compartments. In the table these ordinates are printed in different characters, so as to distinguish them from the other figures, in the compartments.

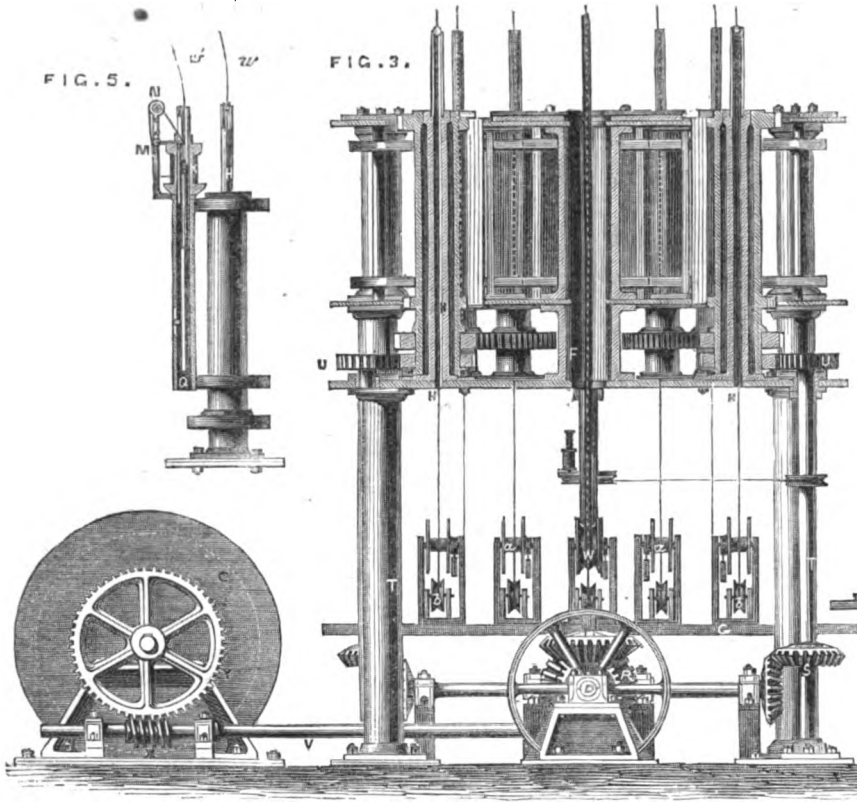

FIG. 4.

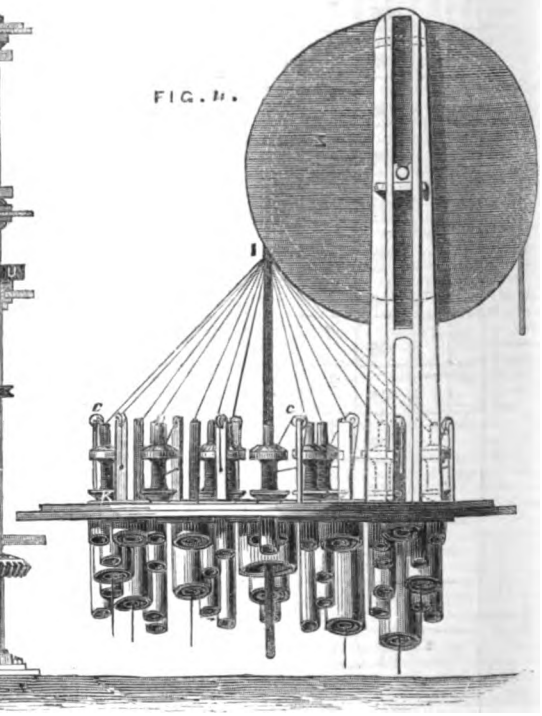


MESSRS. HALL AND WELLS' IMPROVED ELECTRIC TELEGRAPH CABLES.

THE following is the specification of Messrs. Hall and Wells' Improved Electric Telegraph Cables, to which reference is made in our leading article upon the subject, page 295: "Our Invention consists, First, in perfectly insulating the conducting wire or wires as follows:—We commence by covering the conducting wire or wires with a spiral layer of cotton, and we prefer to use grey or unbleached cotton, as being the most pure. We then cover the cotton with a strip or strips of rubber cut from the bottle or other form in which it is imported, without being masticated or otherwise operated upon; we lay on this strip or strips spirally, and with overlap. We then wind round outside of the spiral overlapping layer or layers of rubber a thread of vulcanised rubber covered with cotton or other like suitable fibre. We perform all these coverings at one and the same operation, and employ for so doing a spiral-covering machine calculated to lay on the several coverings in the order above described. In some cases in place of the covered thread of vulcanised rubber before mentioned, or in addition thereto, we apply further spirally-laid coverings of pure rubber laid on alternately in opposite directions, and envelope the whole in a similar covering of vulcanised rubber or not as may be desired. The whole of these operations may be performed in one machine. Our invention further consists in projecting insulated wire or wires, whether insulated in the manner hereinbefore described or otherwise, in the following manner:—We commence by applying a covering of gutta percha of the ordinary kind, where that may be found desirable, and this gutta percha we surround with plain hemp or other fibre free from oil, tar, and grease, braided or spirally laid on. Where gutta percha is not used, the plain hemp or other fibre is laid immediately upon the rubber or other insulating material. Then we braid, wrap, or lay a coating of spun yarn or other fibre saturated with tar or other preserving substance. We apply these two wrappings at one and the same operations by a machine similar to that which we employ in performing the first part of our invention, or by any equivalent means. The spun or tarred yarn or wrapping of rubber is then protected by wires laid on by means of a hollow-tube braiding machine at one operation, whereby one set of wires is laid longitudinally without any twist, while another set forms the braiding, and encloses the longitudinal wires.

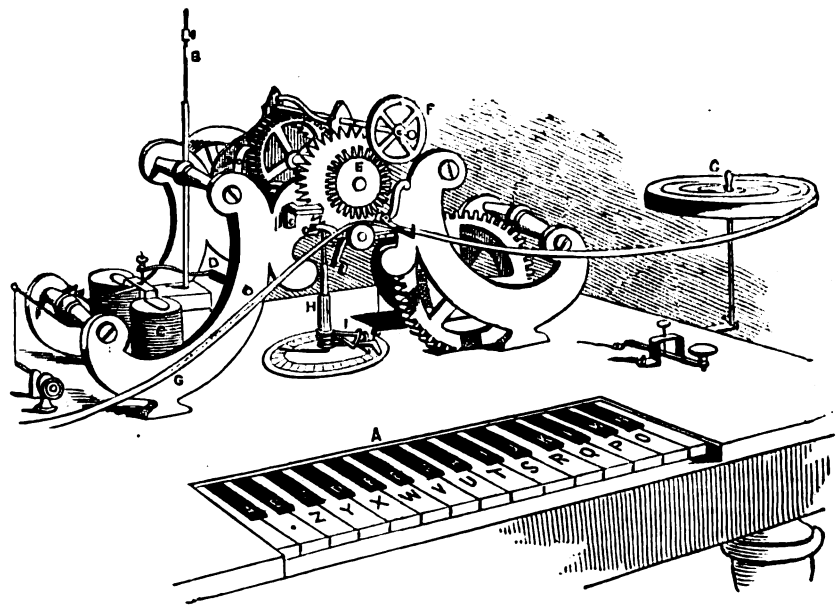
"In the annexed engravings we have represented a spiral-covering machine, with the parts of it arranged in a manner suitable for carrying the earlier operations of our invention into effect. This machine is so constructed as to lay on the hemp-spun yarn, or other fibre for the protection of the insulated wire, simultaneously with the insulation of the same. Fig. 1 is a side elevation, and Fig. 2 an end elevation of the said machine. *A* is the framework of the machine; *B* is a drum on which the conducting-wire which is to be operated upon is wound, and from which it is delivered as the covering proceeds, being put in tension, if desired, by means of the weight *W* and the counter-weight *w*; *C* is a drum on which it is received and wound when the winding-on of the spiral coverings is completed; *D* is the main driving-shaft, which is driven by pulleys on its extremity, and upon which at its other extremity, is fitted

Digitized by Google

the worm *E*, gearing into the worm-wheel *F*. The shaft *G*, on which the worm-wheel *F* is mounted, carries at its extremity the belt pulley *H*, round which passes the belt *I*, which also passes round the drum *C* and drives it, thereby drawing the conducting-wire through the machine from the drum *B*. When the drum *C* becomes full the belt *I* slips, and thus acts as a friction belt, as is well understood. The wire, after it leaves the drum *B*, passes over the pulley *J* and under a small friction-pulley into the machine. *a*, *a*, *b*, *c*, *d*, *e*, and *f* are revolving bobbins mounted and fitted in the manner shown, and driven by cords passing round the pulleys *a'*, *b'*, *c'*, *d'*, *e'*, *f'*, on the shaft *D*. The bobbins *a*, *a*, which are attached to one head, carry unbleached cotton; the bobbins *b* and *c* carry the thin strip rubber; the bobbin *d* carries the vulcanized india-rubber thread, covered with cotton or other fibre; the bobbin *e* carries thin strip rubber; and the bobbin *f* carries spun-yarn or other fibre, either saturated with tar or other preserving substance or not as may be preferred. All these are successively laid over the wire by the bobbins as they revolve. As is well understood, between the bobbins pairs of friction-pulleys *p p* are fitted to prevent jibbing or other motion during the manufacture. After it has received the last covering from the bobbin *f*, the wire passes under the pulley *K*, over the pulley *L* (on the shaft *G*) and down to the drum *C*. If it is thought desirable to apply coatings of india-rubber or other solutions or substances between the successive coverings as they are laid on, gauges supported on standards may be fixed for the purpose between the bobbins. The wire having been insulated, and partly protected, with successive coverings in the manner and by the means above set forth, is next conveyed to the hollow-tube braiding machine to receive a wire covering consisting of one set of wires laid longitudinally without any twist, and of another set which encloses them and forms the braiding. In the annexed engravings we have represented a hollow-tube braiding machine, with the parts of it arranged in a manner suitable for effecting this operation. Fig. 3 is an elevation, partly in section, of the machine with the upper portion thereof removed, that portion being shown separately in Fig. 4. Fig. 5 is a detached view, partly in section, of one of the pipes and hollow tubes shown separately. *A* is the frame of the machine; *B* is the drum on which the insulated wire to be covered is wound; *C* is a pulley round which the finished cable passes after it leaves the machine. *D* (Fig. 3) is the main driving shaft which carries the pulleys *E E*, by means of which a steam engine or other prime mover imparts motion to the whole of the machine through the various shafts and wheels shown in the several figures. The insulated wire *W* as it leaves the drum *B* passes under a pulley, and then descends in the centre of the machine, passing into and up through the central tube *F*. The wires *w*, which are to be laid longitudinally along the cable without twist are wound on bobbins *a*, *a*, *a*, supported on the lower platform *G*. After leaving these bobbins they pass respectively under the pulleys *b*, *b*, *b*, and then ascend through the various hollow tubes *H*, *H*, *H*, passing out over the small pulleys *c*, *c*, *c*, and meeting the cable at the centre, as at *J*, Fig. 4. Instead of a single wire passing through each of these tubes, two, three, or more such wires may be led from one or more, or from as many bobbins. Further, in addition to the wires *w* just described the set of longitudinal wires may also comprise others led up through the central tube of the machine alternately between the former ones, so as to be braided in upon the spun yarn or other fibrous covering of the wire to increase the strength. The braiding wires *w'* are carried upon the bobbins *K*, the construction of which will be best understood by reference to Fig. 5. The bobbin *K* runs loose upon the tube *L*, and the wire *w'* as it leaves the bobbin passes through a steel eye or through a slot in the tail-piece *M*, and, ascending, passes over the pulley *N*, on the upper end of the same and down through a hole in the latch *O* which is jointed to the tail-piece. It then passes down under a pulley, which pulley is secured to the upper end of the weight *Q*. From the weight pulley it again ascends, and after passing through the latch *O*, leaves the tube *L* through a hardened steel eye. The action of this part of the apparatus is in all respects similar to the action of similar parts in the ordinary braiding machine, and, therefore, needs no description. When the shaft *D* is put in motion by means of a belt on the pulley *E*, the bevil wheel *R* on the said shaft communicates motion through the bevil wheels *S*, *S* to four vertical shafts *T*, *T*, which carry at their upper parts the toothed wheels or spur gear *U*, *U*, by which the braiding tubes are driven. We have adopted four upright driving shafts and separate spur gear for each, in order to ensure a better working and more uniform wear than could be obtained if a single upright shaft and one set of spur gear only were employed as in the ordinary light machines. The shaft *D* carries a worm taking into a worm wheel on the shaft *V*, which shaft also carries a worm *X*, which drives the worm wheel *Y* on the axle of the pulley *C*. As motion is imparted to that pulley through these parts, the wire which passes around it is drawn through the machine, descending over the great pulley *Z* to the pulley *C*, as it leaves the machine in its finished state. By this arrangement of the receiving pulley *C*, and this method of driving it, we avoid producing that excessive friction and wear which would be occasioned in portions of the machinery if the power for driving it were taken off at any point remote from the main shaft *D*, whereby the bevil wheels and other gear would be unequally worn, and the working of the machine thus deranged.

"In addition to the wire covering which this machine is intended to lay upon the cable, it may also be furnished with an arrangement for laying on a final covering of spun yarn or other fibres saturated with tar before the wire is braided on. This may be done by means of a revolving bobbin *B'* mounted upon a platform *P'* in the central part of the machine, as shown at Fig. 2. This bobbin may be driven by a small belt leading from a pulley on any one of the upright shafts *T*, or in any other convenient manner."

PROFESSOR HUGHES' ELECTRIC TELEGRAPH APPARATUS.



A Key Board; *B* Vibrating Spring; *C* Electro-Magnet; *D* Detent; *E* Type-Wheel; *F* Ink Roller; *G* Paper printed upon; *H* Revolving Shaft; *I* Revolving Arm or Circuit Closer.

IN a former volume we published as full a description of Professor Hughes' system of type-printing telegraphs as we could at that time obtain, and also an account as full as we were permitted to make it known, of the means adopted by that gentleman for rendering feeble currents effective for communicating signals. More recently Professor Hughes has brought forward an improved method of insulating submarine telegraph wires. As these inventions have excited considerable attention, and as Professor Hughes claims very large and important advantages for his systems, we avail ourselves of a paper recently read at the Society of Arts, by Mr. H. Hyde, as a means of giving a more detailed account of them than has yet appeared in our columns. Mr. Hyde is intimately associated with Professor Hughes in his electrical undertakings, and his description may therefore be taken as reliable. Slightly condensed it is as follows:—

INSULATION.

Gutta percha has been found to be the best insulator for long submarine lines. This substance, however, is more or less porous; minute flaws may exist, which do not show themselves until some time after the immersion of a cable. This was exemplified by Mr. Henley, who discovered a flaw in his submarine cable, which did not show itself until it had been three or four days under water. To meet those defects, to fill up any minute pores in the gutta percha, and also to cure any accidental fracture or puncture of it, Professor Hughes introduces a viscid semi-fluid substance, of a non-conducting character, between the conducting wire and the gutta percha, or the wire may first be coated with gutta percha, and the viscid fluid introduced between the layers of gutta percha. As soon as a puncture is made in either of the gutta percha coatings, the semi-viscid fluid oozes out. It is of such a nature, that it hardens when it comes in contact with the surrounding water. This hardening or coagulating property allows no more of the fluid to ooze out than is necessary to fill the fracture, and at the same time to glue and unite the separated parts of the gutta percha. The first feature in this form of cable is its self-restoring power; but it has another, and perhaps more important one. It has been shown, I think by Professor Faraday, that a fluid which cannot be decomposed by electricity is the most perfect insulator. Should this be demonstrated in practice, the invention of this form of cable must be valuable as a means for greatly increasing the non-conducting power of the medium surrounding the conducting wire. It is well known that cables become defective in insulation after being submerged for some time. It has been supposed that the forces of the electric current burst the gutta-percha covering under certain circumstances. It has also been urged that, in consequence of this tendency, battery power should be used instead of induced currents. Professor Hughes has demonstrated that voltaic currents exert no mechanical force whatever upon the insulating coating of a conducting wire. If there be a defect in the coating it may be enlarged by strong currents, either voltaic or induced. But if there be no pore or crack through which the current can first commence its work of destruction, no voltaic current would exert sufficient force to tear a piece of paper. This has been shown by putting a piece of cable, three feet long, made upon Professor Hughes' plan, into a bath of salt water. Its complete insulation was tested by a delicate galvanometer and a battery of 500 cells. A fracture, an inch long, was then made through the gutta percha and the viscid substance, allowing the salt water to reach the wire; the galvanometer immediately was deflected from zero to 90°, showing dead earth. In the course of five or ten minutes the viscid substance worked its way around the uncovered wire, and oozed out to the water through the fracture. It then coagulated, and thus repaired the injury, and completely restored the insulation. The whole force of the current from the 500 cells was kept constantly passing into the wire during the whole of this operation. In illustration of the varied effects of different descriptions of fractures upon submerged cables, it may be instructive to note that if the conducting wire be made bare by a fracture of considerable size, having breadth as well as length, the immediate effect will be dead earth, or the instantaneous deflection of the needle to 90°. If the fracture be fine or narrow, the effect will be a deflection of the needle to a greater or less extent, say from 70 or 90°, with a constant vibration of from five to ten degrees, or even more. This deflection and the vibrations will continue as long as the current is kept upon the wire, and often resemble the vibrations produced by a manipulator. This peculiar phenomena may, in some degree, account for the peculiar vibrations which so much puzzled the electricians during the short life and last moments of the Atlantic cable. These vibrations are probably produced by the decomposition of water by the electric current. The hydrogen gas escaping from the point of contact with the wire in an elongated bubble fills the fracture while passing through it, thus alternately opening and closing the circuit.

INSTRUMENTS.

The needle, the Morse, and the House instruments, as well as all minor ones hitherto worked with one wire, require an average of five or more electrical impulses or waves, or the time equal to this number, to transmit one letter. The recording in Roman type each letter of a message by a single wave, upon one wire, is the triumph of the Hughes' system. To accomplish it, several requisites are necessary, which it may be proper to state, and then proceed to show how they are each obtained, and united in one harmonious whole, producing that life-like automaton

Digitized by Google

present to demonstrate before you what is advanced, and practically speak for itself in plain English. These requisites are, first, synchronous motion; secondly, an electro-magnet, by which the timing of the electrical wave may be accurately measured; thirdly, a writing apparatus, by which the message may be correctly, rapidly, and easily transmitted; fourthly, a printing apparatus, by which the operator can record the message unerringly upon his own instrument, as well as upon the one at the distant station. Many inventors have attempted to make an instrument by which a letter could be sent by one wave, but without success. One reason was, that they had no governor of sufficient velocity and accuracy to produce rapid synchronous motion. Professor Hughes applies a vibrating spring to govern his instrument. It is a well-known law that a certain number of vibrations produces a certain musical tone; therefore, if two or more springs have the same tone they must necessarily have a similar number of vibrations in the same time. The instruments are kept in motion by a weight acting upon a train of wheels, the spring governor acting upon them by means of an ordinary escapement. These vibrations may succeed each other with any degree of rapidity required. They are regulated by a small weight attached to the spring, and raised or lowered until the number of vibrations or desired tone is produced. This can be done easily and quickly, although the instruments may be any number of miles apart—say between London and Paris, or Ireland and America. The type-wheels of the instruments now exhibited, revolve at the rate of one hundred and twenty revolutions per minute, and the governor makes fifty-six vibrations for each revolution of the wheel.

The Magnet.

The Hughes' magnet is of peculiar construction. A permanent magnet polarizes the cores of an electro-magnet, and holds an armature in contact with its poles. A spring is attached to this armature, and so adjusted as to exert a counteracting power a little weaker than the force of the magnetic attraction. If, therefore, the magnetic force be diminished, the armature is removed from the poles of the magnet by the force of the spring. The arrangement is such that the current of electricity passing through the coil when the circuit is completed, induces an opposite magnetism to that of the permanent magnet. The electrical force, therefore, which works this instrument need not be sufficient to induce such a degree of magnetism as to render the core sufficiently magnetic to attract an armature to its poles—the practice in all other recording telegraphs. For instance, if the cores of the electro-magnet, polarised by the permanent magnet, have a holding force upon the armature of ten, and the spring attached to the armature be adjusted with an opposing force of nine, then a current of one reducing the force of the electro-magnet would cause the spring to rise with the force of nine. This arrangement can in practice be so nicely adjusted as to work with a very feeble current, and accurately measure the timing of the electrical wave. The armature being mechanically restored to contact with the poles, has the advantage of being acted upon by the maximum power of the electro-magnet, instead of a power lessened by more than the square of the distance the armature has to be attracted, as is the case in the relay magnets used in connection with the Morse and other systems.

Transmitting Apparatus.

The letters of the alphabet, as well as a dot and a blank, are marked on twenty-eight keys, arranged like those of a piano, save that they are alternately black and white. These keys correspond to twenty-eight holes arranged in a circle on the horizontal floor or table of the instrument, immediately in front of the keys. Each key is connected by a lever with a little steel knob, which, when the key is pressed down by the finger, rises up through one of the holes. An arm, connected with a vertical shaft, sweeps over the twenty-eight holes. If a key marked with a particular letter be touched, the knob corresponding with this letter rises, the revolving arm passes over it, and for the instant closes the circuit, and allows an electrical impulse to be transmitted. This impulse, by arrangements which will be described in the printing apparatus, causes the particular letter to be recorded on a slip of paper in printer's ink. The instant the arm passes over the little raised knob the circuit is broken, and if the finger were held a hundredth part of a minute on the key, the hand would pass again over the knob, and the letter would be repeated. To prevent this the hand carries, after the portion of it which rides over the knob and completes the metallic contact which closes the electrical circuit, a little inclined plane, which throws the knob out of its position, so that the hand cannot pass over it on any future revolution after the first contact. This arrangement is rendered necessary to prevent the repetition of letters, on account of the extreme rapidity of the revolving arm and recording apparatus.

Printing Apparatus.

A shaft, which revolves seven times faster than the type-wheel, has a fly-wheel upon it to overcome the inertia of a small shaft which moves the printing press. This shaft is locked to the fly-wheel shaft by means of a clutch, which rests upon a small inclined plane. Whenever this clutch is kept upon the inclined plane, by means of a detent, the fly-wheel shaft revolves independently of the small printing shaft; but as soon as the detent is moved by the action of the armature of the electro-magnet, the clutch locks both shafts together, and the small shaft is made to revolve one revolution, when the clutch again rests upon the inclined plane, which lifts it off the fly-wheel shaft. A cam is attached to one end of this shaft, which lifts the press and the paper upon which the message is to be printed against the type-wheel. The time of the locking of the shafts depends upon the arrival of the electrical wave, and thus, with two instruments in perfect harmony, the operator has the printing apparatus of the distant instrument as completely under his direction as the one before him. But to correct any minute variation in time between the instruments in circuit, there is a corrector or wheel attached to this shaft, with hook-shaped teeth, which mesh into corresponding cavities in the type-wheel. The latter being loose upon the shaft, or only held by friction, is removed backwards or forwards by the corrector to exactly the same position as the type-wheel on the instrument from which the message is being sent. This correction takes place in the act of printing every letter. There is also upon this shaft a cam, so arranged that the moment the armature falls off the electro-magnet and opens the detent, it forces the detent up, and restores the armature to its original position upon the poles of the magnet.

Another new feature in this instrument is its power of cutting off at will all offices except the one to which it is desired to communicate. This is accomplished by a flange on the type-wheel—this flange having a space cut out opposite a certain letter, and each office having the flange cut out at different letters from each other. A bolt is made to slide through the space, and moved through by the action of the instrument. If this bolt is sent through at the moment the space is opposite, it permits the instrument to run, if not, it goes against the flange and locks the type-wheel. The operator, knowing at what letter a certain instrument will be unlocked, touches that key. This allows the instrument he wishes to communicate with to run; and he can send the message to that one, the other offices being unable to get it, as they would be locked, and could not bring their instruments into unison with the one sending the despatch. Thus, it is absolutely secret in its transmission, and, if necessary, anyone could send his own message, as it is only necessary, to insure its safe arrival, to touch the right keys, which are all lettered.

The electrical circuits are extremely simple. The earth-wire connects with the steel pins or knobs on the keys of the transmitting apparatus, and from the revolving arm through the electro-magnet, and thence through the line and distant magnet to the earth. Reversed currents are not necessary, except on long submarine wires. There may be as many instruments in circuit as may be desired. The European news, consisting of about 3,000 words, by the arrival of each Transatlantic steamer, is transmitted by this instrument from Boston to New York, a circuit of about 300 miles, at the rate of 2,000 to 2,500 unabbreviated words an hour. There are 25 stations on the circuit which receive copies of the news, all of which are printed in plain Roman type by the Boston operator, all the instruments receiving the message at the same time, the receiving clerks at each station having simply to hand the copy as it arrives to the party entitled to receive it.

The mode of operating with this instrument is extremely simple, and easily acquired. The office desiring to transmit a message, calls the station by touching the keys in a pre-arranged order, the distant office at once returns the signal "O.K.," or all right. The manipulator then commences the message, first striking the zero key to start the distant type-wheel in unison with his own. If the message is received correctly he is allowed to finish, and then the operator at the distant office gives the return signal of all right; if there is a mistake the receiving office touches his key-board, which throws extra letters to the transmitting station, and he then commences again from the point where he made a mistake. There can be no mistake, however, if the operator touches the right key, and manipulators become so expert that they seldom touch the wrong one; if they do, the error is shown by the copy of the message on their own instrument, and immediately corrected.

If I have succeeded in conveying a clear and intelligible impression of the principle of the Hughes' system, it may be proper to invite your attention to what appear to me to be natural deductions. *Accuracy* is secured by unerring mechanical laws, and not by the skill of the operator, as in the needle or Morse systems. Not only this, but in all other systems, if one of the symbols be missing, another letter is formed by the remaining symbols. *Rapidity* is secured by reducing the labour to its minimum. A single touch of a key prints the letter, instead of three or four vibrations of a needle, or a similar number of motions of a key, as in the formation of symbols to represent letters. Accuracy and rapidity being thus secured, ease and simplicity of manipulation must of necessity follow, and, consequently, the young operator readily acquires his or her education. The instrument, however, is specially adapted to females. The one-wave system is specially important on long submarine circuits, where electrical impulses are limited, one wave being sufficient for a letter instead of five. Great difficulty has been experienced on long cables by the variation of time in the transit of the wave. By this correct timing instrument, simple and perfect compensation is mechanically attained for any length of wire or extent of variation. The sensitiveness of the magnet also enables this instrument to record more waves upon a long circuit than any I have yet met with. The rapidity of an instrument, however, does not consist only in the fact of its extreme sensitiveness, but also in its power to free itself from the influence of a current so soon as the effect of the current has caused the instrument to record the signal or letter sent. This property, attained by the electrical and mechanical combination of scientific laws, embodied in the design and construction of the instrument, and demonstrated by the results produced, must in time remove all doubt of its superiority, while its English tongue represented in plain printed Roman characters, will tend to make it the favourite of the Anglo-Saxon race.

SPENCE'S PATENT IMPROVEMENTS IN THE MANUFACTURE OF STEEL.

The specification of Mr. James Spence's Patent for "Improvements in the manufacture of steel, and in the furnaces employed in such manufacture," about which there was recently much disputing, both at an opposition at the chambers of the Attorney-General, and afterwards, is now before us, and is as follows:—

"My invention consists, firstly, in producing steel from pig iron or other cast iron in a puddling furnace, by regulating the quality or chemical condition of the air (passed into the furnace) by the means hereafter described; and, secondly, in an improvement in the puddling furnace whereby such regulation is effected.

"Ordinary pig iron, or other cast iron, contains an excess of carbon, whilst common wrought iron contains merely a trace of the same. As steel contains an intermediate amount of carbon, the object in steel puddling is to decarbonize the pig or cast iron down to the limit of steel, and upon reaching that limit strenuously to avoid further decarbonization, otherwise the product will be converted more or less into wrought iron. Now, as the principal agent in the process of decarbonization is the oxygen contained in the air passing into and through the furnace (which, having a chemical affinity for the carbon, combines therewith, and removes it in a gaseous form), it follows that in the first stage of this process a full supply of oxygen is required, and that in the second stage none should reach the metal. In other words, in steel puddling the first stage requires heat with oxygen, and the second heat without oxygen. To effect objects thus differing and opposed, requires an apparatus having different modes of action. The common puddling furnace hitherto used in this manufacture has only one mode of action, and in consequence steel has been made therein with difficulty and uncertainty by the aid of large quantities of cinder or other materials, and by the closing of the damper at the latter stage of the process, and thus the uniformity of the product depended greatly on the judgment and dexterity of the puddler, and, moreover, the closing of the damper caused a reduction of the temperature, which had an injurious effect upon the working of the metal in the after processes of collecting, welding, and balling. In order to obviate these difficulties, and to obtain a more uniform product, I construct

Longitudinal Section of Mr. Spence's Steel Furnace.

and work the puddling furnace in the following manner:—I build my puddling furnace with two grates (one behind the other), divided by a bridge, the ash-pit of each grate being entirely enclosed, and having a door or doors in the front or side. The grates being both of the same length (about three feet three inches), I prefer to make the inner one about two feet four inches in width, and the outer or end grate about one foot nine inches in width. I also place the fire-bars of the first or outer grate about four inches below the level of the bars of the second or inner grate. It will be seen that by this arrangement when the door of the inner or second grate is closed, no air can pass through that fire, whilst the air which has escaped combustion in passing through the first or outer grate before it can reach the metal must pass over the incandescent fuel on the second or inner grate, and will be thereby deprived of its remaining oxygen. The fire-bridge of the ordinary puddling furnace is a low wall of fire bricks extending across the furnace behind the grates. The first bridge, or that which divides the two grates, I construct in the ordinary manner, but the second or that which divides the inner grate from the sole of the furnace, I construct as follows:—Instead of the upper course of bricks I fix a ⊓-shaped tube of refractory clay, closed at one end and connected at the other with a supply of air which may be given under pressure. The side of this tube next to the metal is furnished with a longitudinal opening, through which such air will pass directly on to the metal."

In order more clearly to illustrate this part of his invention, Mr. Spence adds a drawing, from which the accompanying engraving has been prepared. It represents a longitudinal section of a puddling furnace constructed according to his invention, and is thus described by him:—

"*A*, *A*, are the exterior walls of the furnace; *B*, *B*, the dome; *C*, *C*, the sole, and *D*, *D*, the chimney. *E* is the first or outer grate with its ash-pit *F*, which is enclosed on all sides and furnished with a door or doors; and *G* is the second or inner grate with its respective ash-pit *H*, also enclosed and furnished with a door or doors; *I* is the first bridge which divides the two grates; and *K* is the second bridge, the upper course of which is formed of a tube of refractory clay *L*, *L*, closed at one end, the inner side of which, or that next the sole of the furnace, is furnished with a narrow longitudinal opening *M*, *M*; into this leads a pipe in connection with a supply of air. In operating with this furnace, I proceed to charge it with about four hundred and eighty pounds of pig iron or cast iron. Whilst this is melting, I keep the doors of both the ash-pits, *F* and *H*, open, or nearly open, in order to bring both fires into a state of activity. As soon as the iron is melted, the object is to remove the excess of carbon, and in order to effect this, I close the door of the outer ash-pit *F*, and keep that of the inner ash-pit *H* quite open, and also admit the supply of air through the hollow bridge *L*, on to the surface of the metal. I puddle or work the fluid metal in the usual manner, thoroughly exposing every portion of it to the decarbonizing action of the oxygen. When the metal begins to solidify (technically called "coming to nature") the carbon is reduced to the proportion constituting steel, and as steel is less fusible than cast iron, it passes from the fluid to the solid state. The commencement of this transition is indicated by the appearance of grains above the fluid surface. On observing these grains, I shut off the supply of air through the hollow bridge *L*, open the door of the ash-pit *F*, and close the door of the inner ash-pit *H*. This being done, the necessary heat is maintained by the outer fire for the further work of collecting, welding, and balling the metal, whilst the air which may have passed unconsumed through that fire, having to traverse over the incandescent fuel on the inner grate, is thereby deprived of the remainder of its oxygen, and rendered inert. It will be found that great advantage arises from the use of this method, as it substitutes mechanical contrivance for the very uncertain skill of the puddler, and thus greatly reduces the difficulty and uncertainty of the manufacture. When the balls are formed they are taken to the hammer, and worked out as usual. In place of making the outer grate to draw or open to the front, it may be built to open at the end, to suit the convenience of the works. It is also not absolutely essential to enclose the ash-pit of this fire, but in practice I find it desirable, as it gives a more perfect control over the process. The complete enclosure of the inner ash-pit, as described, is absolutely necessary, and forms an essential feature of my invention. The dimensions above given for the grates are those which I prefer, but they should be regulated to suit the particular description of coal used as fuel. When steel of a full degree of hardness is required, I find it expedient to use but one sort of iron, and I prefer that made from the hematite ore, or that of the Forest of Dean; but when a soft steel is desired, I find it preferable to work a mixture of different sorts of iron. It is the common practice to introduce fluxes or salts into the furnace to assist in this manufacture, but their use is not absolutely necessary or essential to the production of steel in the furnace described, and their benefit is more or less uncertain and contingent on their equal and thorough diffusion throughout the entire mass. When this equal diffusion can be depended upon, the puddler may use as a flux an alkaline base, which will unite with and abstract the impurities of the iron. If the quality of the steel to be produced be the first consideration, I prefer to employ the muriate of ammonia as a flux, which I consider the best, the next best being the sesquicarbonate of soda; but when economy of cost is the leading consideration, the chloride of sodium (common salt) may be used with some advantage. The precise flux to be used beneficially can only be determined by the character and quality of the particular kind of iron or mixture of iron with which it is to be employed, as no two kinds of iron contain exactly the same impurities. In all cases the flux should be reduced to a fine powder, and be introduced into the furnace, and thoroughly incorporated and diffused throughout the mass of metal at the commencement of the boil."

It is stated that a sum of £31,000 will be annually saved in the Ordnance Department by the introduction of photography for the purpose of surveying.

MR. SCOFFERN'S BOOK ON NEW RESOURCES OF WARFARE.

(From the *Engineer*.)

We have given the title of this work in full, in order that our readers may be enabled to form a judgment as to the relations between promise and performance in Dr. Scoffern's book. An advertisement with the title *in extenso* would naturally lead one to expect an exhaustive treatise on the subject: the book itself is a lanky and meagre affair of seventy pages of leaded type, containing scarcely any original matter, with a good deal of argumentative and theoretical exposition concerning the comparative effects of vertical and horizontal shell-firing. Dr. Scoffern is known as a chemist of some repute, who has, for some time past, been engaged in experimenting upon explosive compounds, and who, if he has not added to our store of information on that subject, has at least popularised and systematised what was already known. The book has evidently been hastily written to meet the present demand for information concerning the specialities of the Armstrong gun, of which there is a figure and description, differing in some trifling details from that given in the MECHANICS' MAGAZINE of the 25th February. With regard to the theoretical and argumentative matter, it reminds us not a little of Captain Fluellen's didactics anent the "disciplines of war;" but there is too much of "tiddle-taddles and pibbles-pabbles" which the valorous Welshman so emphatically condemned.

Dr. Scoffern opens with the following "dreadful note of preparation:"—

"At no period since the discovery of gunpowder has the application of science to purposes of destruction been more arduously attempted, or more successfully achieved, than during the past ten years; and as to afford another illustration of the providential co-ordination of all things, some of the most deadly applications of science to swell the resources of warfare are (so to speak) matters of to-day, just when Europe seems destined to be set on fire, for the purpose of throwing a new light on some disputed readings of the treaty of Vienna. Perhaps never in the whole history of projectiles has an arm of destruction, large or small, awakened for itself so great an amount of popular or lay attention as the Armstrong cannon now formally adopted in our service. *I am able to supply for the first time (?) a full explanation, accompanied by correct (?) drawings of that gun;* a matter of no little interest, it is assumed, at the present epoch."

The italics in this quotation are Dr. Scoffern's, and give the key-note of the book. It must have been rather mortifying to the author to find himself anticipated by the editor of what he calls a "technical illustrated journal." In a foot-note he acknowledges this fact, but with the qualifying reservation, that the editor in question had stated that he could not vouch for the perfect accuracy of the drawings he gave; "and, indeed," continues Dr. Scoffern, "they will be found to differ from my drawings of the gun (obtained from a reliable source, and which I can depend upon) in some important particulars. To cite an example:—The breech-screw of the Armstrong gun is perforated, as described at page 37, whereas the journal referred to depicted it solid. Other particulars of discrepancy will be discovered by reference."

We have at the present writing both drawings before us; but, after a most careful scrutiny and comparison, we have failed to detect any other discrepancy than the one alluded to. This is rather provoking, after the italicised statement in our first extract:—"*I am able to supply, for the first time, a full explanation, accompanied by* CORRECT DRAWINGS, *of that gun.*" On again referring to Dr. Scoffern's drawing, we find in a foot-note that it is no drawing at all! "*This diagram*" he tells us, "is to be regarded in a *functional sense*, not as a copy to a scale!" So we must take the promise of "correct drawings" in a *functional sense*.

THE NEW PATENT LAW FOR INDIA.

(Concluded from p. 288.)

XXIV. It shall be lawful for any person to apply by motion to any of Her Majesty's Courts of Judicature for a rule to show cause why the Court should not declare that an exclusive privilege in respect of an invention has not been acquired under the provisions of this Act by reason of all or any of the objections following (to be specified in the rule); that is to say:—

That the said invention is of no utility; or

That the said invention was not, at the time of presenting the petition for leave to file the specification, a new invention within the meaning of this Act; or

That the petitioner was not the inventor thereof; or

That the specification filed, or the amended specification (if any) does not particularly describe

Digitized by Google

and ascertain the nature of the invention, or in what manner the same is to be performed, or

That the petitioner has knowingly or fraudulently included in the petition or specification, or amended specification, as part of his invention, something which was not new or whereof he was not the inventor, or

That the original or any subsequent petition relating to the invention, or the original or any amended specification, contains a wilful or fraudulent mis-statement, or

That some part of the invention, or the manner in which that part is to be performed, as described in the specification filed, or the amended specification, is not thereby sufficiently described and ascertained, and that such defect or insufficiency was fraudulent and is injurious to the public.

XXV. Any person may, in like manner, apply to any of Her Majesty's Courts of Judicature for a rule to show cause why the Court should not declare that an exclusive privilege has not been acquired under the invention to be specified in the rule by reason of all or any of the objections following (to be specified in the rule) that is to say:—

That such part of the invention is wholly distinct from the other part thereof, and is of no utility, or

That such part of the invention was not, at the date of the petition for leave to file the specification, a new invention within the meaning of this Act, or

That the petitioner was not the inventor of that part of the invention, or

That that part of the invention, and the manner in which it is to be performed, is not sufficiently described and ascertained in the specification filed or the amended specification, and that such defect or insufficiency is injurious to the public.

XXVI. It shall be lawful for the Advocate General at any of the Presidencies of Fort William in Bengal, Fort St. George, and Bombay, or any other person, by order of the Governor General in Council, to apply to any of the said Courts of Judicature for a rule calling upon the petitioner, his executors, administrators, or assigns, to show cause why the question of the breach of any special condition upon which the leave to file a specification has been granted, or any other question of fact on which the revocation of the exclusive privilege by the Governor General in Council under the power herein-before reserved may, in the judgment of the said Governor General in Council depend, should not be tried in the form of an issue directed by the said Court; and if the rule be made absolute, the Court, unless the breach or other matter of fact be admitted, may thereupon direct such issue to be tried, and certify the result of such trial to the Governor General in Council; the costs of such trial, and also the costs of any proceedings in any of the said Courts of Judicature under the provisions of this Act, shall be in the discretion of the Court.

XXVII. Notice of any rule obtained or proceeding taken under either of the last three preceding Sections shall be served on all persons appearing to be proprietors or to have shares or interests in the exclusive privilege under the provisions of Section XXXV. of this Act, and it shall not be necessary to serve such notice on any other persons.

XXVIII. Any of the said Courts of Judicature, if it think fit, may direct an issue for the trial, before the same Court or any other Courts of Judicature, or any principal Court of original jurisdiction in Civil cases of any question of fact arising upon an application under Sections XXIV., XXV., or XXVI. of this Act, and such issue shall be tried accordingly in a summary manner, and if the issue be directed to another Court, the finding shall be certified by the Court before which the same was tried, to the Court directing the issue. If the issue be directed to any Courts of Judicature, the Court by which the issue is tried may, before the finding is certified, direct a new trial of such issue according to the usual course and practice of such Court. If the issue be directed to any Court other than a Court of Judicature, the finding shall not be subject to appeal, but the evidence taken upon the trial shall be recorded, and a copy thereof, certified by the Judge, shall be transmitted together with any remarks he may think fit to make thereon, to the Court by which the issue was directed; and such Court may either act upon the decision of the Court which tried the issue, or direct a new trial if it should appear necessary.

XXIX. If it shall appear to any of the said Courts of Judicature at the hearing of any application under the provisions of Sections XXIV. or XXV. of this Act that, by reason of any of the objections therein mentioned, the said exclusive privilege in the invention or in any part thereof has not been acquired, the Court shall give judgment accordingly, and shall make such order as to the costs of and consequent upon the application as it may think just: and thereupon the petitioner, his executors, administrators, and assigns shall, so long as the judgment continues in force, cease to be entitled to such exclusive privilege.

XXX. If the Court, at the hearing of any such application as last aforesaid, shall think that the petitioner has, in the description of his invention in the petition or specification, or amended specification (if any) included something which at the date of the petition was not new or whereof he was not the inventor, or that the specification is in any particular defective or insufficient, but that the error, defect, or insufficiency was not frandulently intended, the Court may adjudge the said exclusive privilege to have been acquired and to be valid, save as to part thereof affected by such error, defect, or insufficiency, or if the Court shall think that the error, defect, or insufficiency can be amended without injury to the public, they may adjudge the exclusive privilege in the whole of the invention to be valid, and may upon such terms as shall appear reasonable, order the specification to be amended in any of the said particulars; and thereupon the petitioner, his executors, administrators, or assigns shall, within the time limited by the said Court for the purpose, file a specification amended according to such order. Provided that no such amended specification shall have the effect of extending or enlarging the exclusive privilege before acquired.

XXXI. An exclusive privilege shall not be defeated upon the ground that the petition contains a mis-statement, unless such mis-statement was wilful or fraudulent.

XXXII. Whenever it shall be adjudged by any of the said Courts of Judicature that an exclusive privilege as to the whole or any part of an invention has not been acquired, the said Secretary to the Government of India shall, upon the production of the judgment of order, cause an entry thereof to be made in the said book hereinbefore directed to be kept, and shall cause a reference to such entry to be made in the margin of the entry of the specification contained in such book.

XXXIII. If, upon proceedings instituted within two years from the date of a petition to file a specification, the actual inventor shall prove to the satisfaction of the principal Court having jurisdiction in Civil cases, within the local limits of whose jurisdiction the defendant shall reside as a fixed inhabitant, that the petitioner was not the actual inventor, and that at the time of the petition he knew or had good reason to believe that the knowledge of the invention was obtained by himself, or by some other person, surreptitiously or in fraud of the actual inventor, or by means of communication made in confidence by the actual inventor to him, or to any person through whom he derived such knowledge, the Court may compel the petitioner to assign to the actual inventor any exclusive privilege obtained under this Act, and to account for and pay over the profits thereof.

XXXIV. In any action for the infringement of such exclusive privilege the plaintiff shall deliver with his plaint particulars of the breaches complained of in the said action; and the defendant shall deliver a written statement of the particulars of the grounds (if any) upon which he means to contend that the plaintiff is not entitled to an exclusive privilege in the invention. In like manner, upon any application to any of the said Courts of Judicature under Sections XXIV., XXV., or XXVI. of this Act, the applicant shall deliver particulars of the objections on which he means to rely. At the trial of any such action or issue, no evidence shall be allowed to be given in support of any alleged infringement, or of any objection impeaching the validity of such exclusive privilege which shall not be contained in the particulars delivered as aforesaid. If it be alleged that the invention was publicly known or used prior to the date of the petition for leave to file such specification, the places where, and the manner in which the invention was so publicly known or used shall be stated in such particulars. Provided always, that it shall be lawful for any Court in which the action or proceeding is pending, or in which the issue is tried to allow the plaintiff or defendant respectively to amend the particulars delivered as aforesaid upon such terms as shall seem fit.

XXXV. A book shall be kept in the office of the Secretary to the Government of India in the Home Department (such book to be open to inspection without fee) wherein every person filing a specification under this Act, or any person to whom the exclusive privilege may be assigned, shall cause to be stated some place in India where service of any rule or proceedings for the purpose of cancelling or revoking his exclusive privilege may be made, and shall cause a reference to such entry to be made in the margin of the entry of the specification; and may from time to time cause any other place in India to be substituted by similar entry and reference. All such rules and proceedings as aforesaid shall be deemed sufficiently served if a copy thereof be left at the place entered in such book or (if any other place be substituted for the same by entry in the said book) at the place last substituted, by delivering the same to any person resident at, or in charge of, such place; or if there be no person resident at, or in charge of, such place; or if such place be not within the local limits of the jurisdiction of the Court, by causing such rule or proceeding to be sent by post, by a registered letter, directed to such person, at such place; and if any such person shall neglect to make or cause to be made such entry, then service of such rule or proceeding may be effected by affixing a copy thereof to some conspicuous part of the Court House, or in such other manner as the Court may direct.

XXXVI. Act VI. of 1856 shall be of the same force and effect in respect to every petition and specification filed under the provisions thereof before the Act was repealed, and in regard to all proceedings consequent thereon or in relation thereto, and for the purpose of everything done under that Act while it continued in force, as if previously to the passing of the said Act the sanction of Her Majesty to the passing thereof had been obtained and signified in pursuance of the Statute passed in the seventeenth year of the reign of Her Majesty, entitled, "An Act to provide for the Government of India," and as if the said Act had not been repealed, and the term of every exclusive privilege obtained under the said Act is hereby extended, and shall continue until the expiration of fourteen years from the time of the passing of this Act. No exclusive privilege obtained under the said Act by an importer, not being the actual inventor, shall cease to have effect by virtue of the provisions of Section XVI. of the said Act, if the invention be put in practice in India within the period of two years from the time of the passing of this Act.

XXXVII. Every petition for leave to file a specification under the provisions of this Act, or for the extension of the term of an exclusive privilege, shall be written or printed on stamped paper of the value of one hundred rupees.

XXXVIII. In the construction of this Act, the following words and expressions shall have the meanings hereby assigned to them, unless there be something in the subject or context repugnant to such construction.

Words importing the singular number shall include the plural number, and words importing the plural number shall include the singular number.

Words importing the masculine gender shall include females.

The word "invention" shall include an improvement.

The word "manufacture" shall be deemed to include any art, process, or manner of producing, preparing, or making an article, and also any article prepared or produced by manufacture.

The word "printed" shall include "lithographed."

The words "inventor" and "actual inventor" shall include the executors, administrators, or assigns of an inventor or actual inventor, as the case may be.

The word "assigns" shall include grantees of the sole use or benefit in India of an invention, or of the sole use of an exclusive privilege for a limited time.

The word "India" shall mean the territories which are or may become vested in Her Majesty by the statute 21 and 22 Vict. c. 106, entitled "An Act for the better Government of India."

The words "Governor-General in Council" shall include the "President in Council."

The words "Secretary to the Government of India" shall include any Under-Secretary to the said Government.

The expressions "Her Majesty's Courts of Judicature" and "Courts of Judicature" shall mean the courts established by Royal Charter.

Captain Connolly, R.N. (Captain Matthew Connolly, not "W. Connolly," as was printed in our last number), politely directs our attention to a misprint which, we regret to see, occurred in our article upon the rifle rest:—"You have made," he says, "one great misprint, viz., you say, 'for a *sportsman* firing from the kneeling position,' &c., whereas in my manuscript I wrote 'for a *short man*,' &c.; which you will at once see makes a great difference. For an average-size man, the ramrod used as a rest is exactly the proper height in the kneeling position, but for a short man it is rather too high; but in sloping it forward, and resting its head against the upper band, it can be raised or lowered at pleasure." We believe we are not mistaken in believing that Captain Connolly was last week appointed to the command of the Hannibal. We are pleased to see so fine a ship in the hands of so gallant and skilful an officer.

NOTICES.

The MECHANICS' MAGAZINE will be sent free by post to all subscribers of £1 1s. 8d., annually, *payable in advance*. Post Office Orders to be made payable to R. A. Brooman, at the Post Office, Fleet Street, London, E.C.

TO ADVERTISERS.

All Advertisements occupying less than half-a-column are charged at the rate of 5d. per line for any number of insertions less than 13; for 13 insertions, 4d. per line; and for 52 insertions, 3d. per line.

Each line consists of 10 words, the first line counting as two. Wood-cuts are charged at the same rate as type for the space occupied.

Special Arrangements for larger or Serial Advertisements. To ensure insertion, Advertisements must reach the Office by 5 o'clock on Thursday evening each week. None can be received after that time for the ensuing number.

THE demand for Mr. E. J. REED'S paper—

ON THE MODIFICATIONS WHICH THE SHIPS OF THE ROYAL NAVY HAVE UNDERGONE DURING THE PRESENT CENTURY, IN RESPECT OF DIMENSIONS, FORM, MEANS OF PROPULSION, AND POWER OF ATTACK AND DEFENCE,"

has been so great that the Journal of the Society of Arts, the MECHANICS' MAGAZINE, and all other Scientific Journals in which it appeared in December last, are now out of print. The demand still continuing, it has been deemed desirable to reprint it in a separate form. An 8vo. edition of it, in large type, and on fine paper, has, therefore, been prepared, and may now be had at the Office of this Magazine, price 1s.

Our Weekly Gossip.

IN a leading article, the *Morning Post* of Wednesday last makes the very gratifying announcement that the Woolwich Select Committee, the times of whose ignorance the authorities have so long winked at, has been commanded to resign its functions. Our aristocratical contemporary says:—"British inventors may now solace themselves by the reflection that the Select Committee at Woolwich has ceased to exist. It has perished by its own hands. Internal dissensions have been the cause: thus affording not a little countenance to the accusations so frequently brought against it." We further learn from the same source that in place of the Woolwich Select Committee, a "Coast Defence Committee" is to be organised in connection with a school of artillery at Shoeburyness, to the scrutiny of which all projects suggested for the use of the public service will be submitted. We understand that in the constitution of this body the fundamental rule will be recognised that no head of department in Woolwich, or any other arsenal, is to be eligible. Members of the Coast Defence Committee will be public servants, not public masters, as individuals composing the Woolwich Committee were heretofore; and care will be taken that inventions submitted in confidence shall not be appropriated without consent and acknowledgement. "A very expressive peculiarity of the new organisation has now to be announced. Artillery officers, heads of manufacturing departments, are to be called upon to elect either to be civilians or military men; they are either to retire on half-pay, or else to give up their positions. Inventors will have reason to be thankful for this change of organisation."

Admiral Bowles, C.B., the Commander-in-Chief at Portsmouth, has just most judiciously ordered that all steam-ships making trial of speed in Stokes' Bay shall carry a white and blue swallow-tail flag, to indicate the purpose on which they are employed, and to warn all ships to keep clear of their line of course, so that a recurrence of such accidents as occurred at the last trial of the Doris may be prevented. If the general adoption of an efficient means of lowering the boats is still to be delayed throughout the Navy, there is no reason why such should not be made imperative on board vessels during such trials, equally with the flag in question. There are other emergencies besides collisions when it might be wanted, and in the last trial of the ship mentioned its absence was painfully evident.

A correspondent, "Nauticus," sends us the following, which speaks for itself, and for which we thank him: "In an article in the 'Weekly Gossip' of your last number, you have drawn public attention to the late unfortunate collision of H.M.S. Doris, specially ascribing the melancholy loss of life which ensued to the fact of that ship not having been supplied with Clifford's boat-lowering apparatus. Now, however incontrovertible be this inference, permit me to observe that it admits of a wider field of extension, as I am desirous of showing. Some of your readers may call to mind that when this identical frigate made her first trial trip in the Channel some three months ago, during a fresh breeze and heavy swell, a boat temporarily fitted with Captain Kynaston's 'disengaging hooks,' containing a gallant admiral, a post captain, and a crew of 13 men, was successfully detached from the ship while steaming at the rate of nearly 12 knots per hour. Subsequently, when the Doris was commissioned by her present commander, the latter made special application for his quarter-boats to be fitted after the same plan, which was refused on the score that the ship being under sailing orders, there could be no time for completing the necessary arrangements. This was an error, inasmuch as these 'disengaging hooks,' may be fitted to any boat in half-an-hour; be this as it may, the Captain of the Doris, since the melancholy accident alluded to, has never ceased to deplore that his boats had not been fitted on Captain Kynaston's method. The evidence taken before the coroner at Portsmouth records the same feelings of regret, very fairly naming Mr. Clifford's invention in conjunction with the Captain's. With reference to another part of the article originally quoted, I would add that *two minutes* is ample time to allow for a vessel, which has any pretensions to a man-of-war, to detach her quarter-boats fitted with the ordinary tackles, after once her way is stopped, as was the case in the Perseverance's violent collision, but not in the comparatively gentle shock which the Doris sustained in brushing away the sloop's mast with her 'whisker.' Considering the present disabled condition of Captain Kynaston renders him dependent on the good offices of his friends, and the courtesy of the Press (and to none is he more indebted than to yourselves) to bring his invention fairly before the public, I shall be glad if you can devote a small space to the substance of this letter as an act of justice to that officer, which does not tend in any shape to qualify Mr. Clifford's claims on public consideration, and which cannot be said in any way to violate the well-known impartiality of your columns."

We have had a great deal of discussion lately respecting the invention of liquid-fire shells. Captain Norton's name has been very prominently connected with the subject, but we have the gallant officer's authority to state that he lays no claim whatever to the use of any specific chemical substance for the purpose, his improvements being confined to the appliances by means of which such substances may, in his belief, be safely and effectually used. Dr. Scoffern makes an ambiguous claim in respect to the use of such substances, but his language on the point is very indefinite, both as to the material and as to time. A letter from Mr. Macintosh, whose patent for such shells has been too much lost sight of, puts the matter in its proper light in so far as shells charged with bisulphuret of carbon and phosphorus is concerned. He says:—"Permit me to state that 'a shell filled with coal-tar naptha mixed with phosphorus and bisulphuret of carbon, having a bursting charge sufficient to open the shells, which, when exploded, scatters its contents in all directions—the shower of inflammable material falling among cavalry and troops ignites spontaneously, causing their immediate disorganisation and destruction. Fired into shipping, these shells, bursting on deck or below, cause the same results; fired into harbours, dockyards, or towns, the result is alike destructive and decisive.' The above is extracted from my patent—No. 1774. In 1853 I offered my invention to the Government, but Lord Panmure, when Minister of War, interdicted the sealing of my patent, on the grounds of its efficacy and great value, which interdict has since been removed by his lordship. The patent has been sealed and consequently made public."

A long and valuable letter on rifles, by Major W. F. Nuthall, of the Bengal Army, appeared in the *Morning Post* of Tuesday, April 26. We have not space to reproduce this letter, but we refer to it for the information of those of our readers who are especially interested in the rifle question. The following description of the Emperor's new cannon appeared in the French journals:—They are internally grooved, as in the rifles or carbines "*de précision*." The calibres are reduced to two dimensions only—12-pounders for siege guns, and 4-pounders for field batteries. For the navy the calibres remain unaltered. The solid ball is done away with, the projectile being one which strikes like a full shot and then bursts like a shell, thus having a double effect. It is fitted with waddings of lead, which enter into the grooves of the gun, and give the requisite precision to the aim. This new piece is equivalent to one of 24 of the old system, which is the size ordinarily used for opening a breach. Against a massive butt of masonry a battery of ancient 24-pounders was pointed, some weeks ago, at a distance of 35 metres, viz., that at which fire is generally opened against a rampart. A second mass of masonry, similar to the first, was breached by a battery of 12-pounder new guns, but at a distance of 70 metres. The experiments proved that fewer rounds from the rifled gun were required to open the breach than from the old 24, and at double the distance. The 4-pounder field piece is so small that it may be well termed the artillery rifle, weighing less than 300 kilogrammes. Six gunners can carry it on their shoulders without difficulty. The charge of powder is only 500 grammes, and sends the ball four kilometres.

The conversion of blotting-paper, or waterleaf, into a substance very nearly resembling parchment, is one of the scientific marvels of the day, and it promises to become, also, a very useful art. Vegetable parchment, as the new material is called, is simply unsized paper dipped into diluted sulphuric acid, and then carefully dried. The proper strength for the solution constitutes the only question in the process. Messrs. De La Rue are the patentees, and we have before us specimens of the material. It has an opaque and horny appearance, and is very strong. The paper of which bank notes is made are tested by having weights suspended to it, but blotting-paper parchment sustains a much greater strain than bank-note paper. For very many purposes it will undoubtedly supersede sheepskins.

The Royal Albert Bridge, across the Tamar, was opened by the Prince Consort in person, on Monday last. It consists of 19 spans or arches. Seventeen of these spans are wider than the widest arches of Westminster-bridge, while two, resting on a single cast-iron pier of four columns, cross the whole stream of the Tamar at one gigantic leap of upwards of 900 feet, or a greater distance than the breadth of the Thames at Westminster. The total length of the structure from end to end is 2,240 feet, very nearly half-a-mile, and 300 feet longer than the entire stretch of the Britannia-bridge. Its greatest width, as formed only for a single pair of rails, is 30 feet at basement, but its height from foundation to summit is no less than 260 feet, or more than 50 feet higher than the monument.

Patents for Inventions.

PROVISIONAL PROTECTIONS.

Dated April 7, 1859.

865. D. Moseley, of Ardwick, Manchester, Manufacturer. Improvements in the manufacture of cards for carding cotton and other fibrous materials.

867. R. Postlethwaite, of Liverpool, Saddler. An improvement in harness pads for horses.

869. G. Champney, of Halsham, York, Farmer. Improvements in reaping machines.

871. J. Garrett, of Arundel-place, Haymarket, Tinman. Improvements in the construction of goblets, jugs, and other like articles.

Dated April 8, 1859.

873. J. T. Pitman, of Gracechurch-st. Improvement in the construction and use of fire-works for signals. A communication from M. J. Coston.

875. J. Bindley, of Birmingham, Engineer, and J. L. Hinks, of Birmingham, Manufacturer. Improvements in rotatory steam-engines and pumps, a portion of which improvements may also be applied to the bearings of shafts or axles, and other rotating bodies.

877. M. Wheeldon, of Burslem, Glass Cutter. An improvement in looking-glasses and mirrors.

879. M. A. F. Mennons, of Paris. Improvements in the treatment of mineral phosphates of lime. A communication from B de Siebenthal.

881. W. Hooper, of Mitcham, India Rubber Manufacturer. Improvements in insulating and protecting telegraphic conductors.

883. W. Henderson, of Alderley Edge, Chester, Chemist. Improvements in treating certain ores and in obtaining products therefrom.

885. E. R. Handcock, of Norfolk-st., Strand, Esq. Improvements in steam and other motive power engines.

Dated April 9, 1859.

887. E. J. Hughes, of Manchester. Improvements in the manufacture of woven fabrics. A communication from E. Davies.

889 J. H. Young, of Great College-st., Camden Town. Improvements in setting-up (composing) and distributing types.

891. J. H. Johnson, of Lincoln's-inn-fields. Improvements in the manufacture or production of the ferrocyanide and cyanide of potassium. A communication from J. V. Lucas.

893. J. Martin, of Islington, Manufacturer. Improvements in the materials used in the manufacture of bonnet fronts and ruches.

895. W. E. Newton, of Chancery-lane. Improvements in steam engines and boilers. A communication from E. G. Boileau.

897. R. Brown, of St. Paul's Churchyard. Improvements in stoves and apparatus for warming and ventilating apartments and buildings.

Digitized by Google

Dated April 11, 1859.

899. R. Wappenstein, of Manchester, Medallion Engraver. Improvements in cop tubes, and in machinery or apparatus for placing the same on the spindles used for spinning and doubling fibrous materials.

901. J. Anderson, of Liverpool. Improvements in the construction of the furnaces of bakers' ovens for the purpose of consuming smoke, which improvements are also applicable to the consumption of smoke in other furnaces.

903. L. Wimmer, of Vienna, Baker. An improved preparation for killing beetles.

905. W. Rowan, of Belfast, Engineer. Improvements in spinning flax, hemp, and other fibrous materials.

907. W. S. Clark, of Aberdare, Glamorgan, Mining Engineer. Improved means of loading ships or vessels with coal, and of separating or removing small coal therefrom.

909. J. Marland, of Southport, Lancaster. An improvement in the manufacture of cop tubes.

Dated April 12, 1859.

913. G. J. Johnston, of Ashley, Cambridge, Machinist. Improvements in drills, for drilling of corn, seeds, and manure.

915. W. E. Newton, of Chancery-lane. Improvements in the manufacture of iron. A communication from W. Kelly.

917. C. Burrell, of Thetford, Engineer. Improvements in apparatus for screening corn and seeds.

919. J. Crossdale, of Islington, Boot Maker. Certain improvements in boots and shoes.

921. R. A. Brooman, of 166 Fleet-st., London, Patent Agent. Improvements in the preparation of red dyes. A communication from Messrs. Renard Frères.

Dated April 13, 1859.

923. R. Emery, of King-st., St. James's-sq., Gentleman. Certain improvements in carriages for common roads.

925. H. Eckhorn, of Cranbourne-st., Leicester-sq., Manufacturer. Improving and regulating the production of light in lamps, to which he gives the name of "Universal lamp regulator."

927. J. Apperly, Cloth Manufacturer, and W. Clissold, Engineer, of Dudbridge. An improved construction of fulling machine.

929. A. R. Johnson, of St. John's Wood, Gentleman. An instrument for damping, severing, and affixing postage and other like stamps.

931. W. A. Gilbee, of South-st., Finsbury. Improvements in the construction of the axles of railway and other carriages. A communication from M. Tenting aîné.

933. J. Hughes, W. Williams, and G. Leyshon, of Brierley-hill, Stafford. Improvements in the manufacture of tin and terne plates.

Dated April 14, 1859.

937. H. C. Coulthard, Engineer, and J. Jordan, Pattern Maker, of Blackburn. Certain improvements in steam engines.

939. E. Partridge, of Stourbridge, Engineer and Iron Founder. An improvement in the manufacture of 'pipe' boxes for cart and waggon axles.

941. E. Dowling, of Little Queen-st., Holborn, Scale Maker. Improvements in parts of scales or weighing machines, and in balance weights used for those articles, which are also applicable for other purposes.

943. A. McDougall, of Manchester, Chemist. Improvements in coating metallic surfaces.

945. S. Barnwell, of Coventry, Manufacturer, and A. Rollason, of Birmingham, Chemist. Improvements in the manufacture of umbrellas, parasols, hats or hat covers, caps, capes, coats, mantles, dresses, gloves, and other similar articles.

Dated April 15, 1859.

947. W. A. Gilbee, of South-st., Finsbury. Improvements in the construction of buffers for railway and other carriages, also applicable to other purposes where springs are employed. A communication from M. Tenting aîné.

949. G. Ashcroft, of Cardiff, Engineer. Improvements in working presses and other hydraulic machines.

951. H. A. Silver, of Cornhill, India Rubber Manufacturer. Improvements in insulating wire for electric telegraphs.

Dated April 16, 1859.

953. T. White, of Edgbaston, near Birmingham, Managing Clerk. An improvement or improvements in frames or stands for holding liquor bottles, pickle jars, cruets and castors, and for holding bottles and vessels generally.

955. L. Collier, of Rochdale, Machine Maker. An improved feeding apparatus, applicable to grain, loaf sugar, drugs, or other similar materials.

957. W. E. Newton, of Chancery-lane. Improvements in the manufacture of alumina. A communication from Mr. Le Chatelier, of Paris.

959. A. Courage, of Bagillt, Flint Smelter. An improved method of obtaining the metallic particles contained in fumes or vapours from lead and other smelting works.

961. J. Sidebottom, of Broadbottom, near Mottram, Cotton Spinner. Improvements in the construction of tubes and partial tubes, and in machinery or apparatus for placing them on the spindles of machines used in spinning, doubling, winding, and warping, also improvements in machinery for making such tubes and partial tubes.

963. N. Kenward, of Sutton. Improvements in machinery for obtaining motive power by fluids.

965. W. Walker, of Liverpool. Improvements in rocket guns. A communication from T. W. Roys.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

997. L. P. Porter, of New York. Improvements in knitting machinery. A communication from J. R. and E. Kilbourn. Dated April 20, 1859.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

(*From the London Gazette, May* 3, 1859.)

2910. J. Ronald. Spinning.

2917. W. S. Yates. Dragging bristles, &c.

2926. E. T. Dunn. Covering of floors, &c.

2933. J. Ronald. Ropes and cordage.

2945. D. Edleston. Textile fabrics.

2946. J. Railton. Looms.

2956. J. Smethurst. Metallic pistons.

2960. J. Davies. Lamp. A communication.

2965. B. Browne. Boots and shoes. A communication.

2971. J. H. Johnson. Boots and shoes. A communication.

2994. W. Burgess. Converting reciprocating into rotary motion. A communication.

2999. J. H. Johnson. Boots and shoes. A communication.

3003. J. Lees and W. Heap. Punching holes.

3006. L. A. Normandy, jun. Shaft tugs. A communication.

14. M. Wigzell. Nail.

37. F. Clark. Knobs and handles.

73. L. A. Normandy, jun. Resinous substances. A communication.

133. W. Betts. Capsules.

154. G. and J. Collier. Washing and drying.

202. B. Templar. Umbrellas and parasols.

238. D. Graham. Driving centrifugal machines. A communication.

242. J. Kerr. Fire-arms.

560. H. Brown. Fabrics.

641. R. A. Brooman. Threads. A communication.

651. G. B. Galloway. Fuel; steam engines.

680. A. Mein. Glass bottles.

740. B. Browne. Switches and signals. A communication.

745. P. P. Boll and H. Reger. Furnaces. A communication.

792. J. W. Hadwen. Threads.

858. F. M. Crichton. Time keepers.

866. A. Chaplin. Steam boilers.

867. R. Postlethwaite. Harness pads.

903. L. Wimmer. Killing beetles.

916. P. Hill and J. Moore. Pile fabrics.

919. J. Crossdale. Boots and shoes.

922. S. Tatton. Treating silk.

951. H. A. Silver. Insulating wire.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed April 29, 1859.

2418. J. Wright.
2419. G. Zanni.
2420. R. W. Chandler and T. Oliver.
2422. L. J. Lewis.
2423. J. Morris.
2428. F. Wrigley.
2431. H. H. and W. F. Henson.
2432. J. Dobson and D. Pearce.
2433. J. Cariss.
2491. J. Richmond, J. Quick, jun., and A. Fraser.
2679. C. Parker.
2711. W. E Newton.
2751. L. Bissell.
2871. A. V. Newton.
235. W. R. Alexander.
237. O. Hussey.
383. J. Evans.
581. J. Fraser.

Sealed May 3, 1859.

2453. V. Blumberg.
2458. J. Fowler, jun., R. Burton, and D. Greig.
2467. R. A. Brooman.
2471. T. Till.
2472. T. B. Smith.
2477. L. Schwartzkorf and F. C. Philippson.
2485. J. Cliff.
2489. J. Jackson, A. Fisher, and J. J. Harney.
2495. J. Wardill.
2510. W. Clark.
2544. J. Benyon and J. W. B. Bowden.
2570. J. H. Johnson.
2595. W. Clark.
2626. J. H. Johnson.
2738. E. Jones.
522. W. Burgess.
530. J. H. Johnson.

PATENTS ON WHICH THE THIRD YEAR'S STAMP DUTY HAS BEEN PAID.

928. U. Scott.
1009. T. Restell.
1020. J. H. Johnson.
1027. W. E. Newton.
1028. N. Defries and G. H. Bachhoffner.
1029. H. Mapple.
1033. R. A. Brooman.
1042. W. Naylor.
1059. A. Chadburn.
1087. A. C. L. Devaux.
1091. L. L. Jardin and J. Blamond.
1211. C. De Jongh.

LIST OF SPECIFICATIONS, &c.

Published during the week ending April 29, 1859.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

STEAM ENGINES, &c., 2142, 2150, 2152, 2153.
BOILERS AND THEIR FURNACES, 2138, 2144, 2147, 2174.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c. *None.*
SHIPS AND BOATS, including their fittings, 2131, 2173, 2181.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 2135, 2136, 2156 2165.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals. *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 2127, 2128, 2130, 2133, 2145, 2146, 2148, 2175, 2178, 2179.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c. *None.*
LIGHTING, HEATING, AND VENTILATING. *None.*
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 2129, 2158, 2159, 2160, 2164, 2171, 2177.
METALS, including apparatus for their manufacture, 2134, 2139, 2162, 2174.
CHEMISTRY AND PHOTOGRAPHY, 2157.
ELECTRICAL APPARATUS, 2168, 2180.
WARFARE, 2149, 2155.
LETTER PRESS PRINTING &c., 2140.
MISCELLANEOUS, 2124, 2125, 2129, 2132, 2137, 2141, 2143, 2151, 2161, 2163, 2166, 2167, 2169, 2170, 2172, 2176, 2182,

2124. A. M. PERKINS. *Improvements in surface condensers.* Dated Sept. 21, 1858.

The patentee employs upright pipes of wrought or cast iron, pairs of which are connected together by horizontal wrought iron tubes, the ends of which are screwed and tinned or soldered, and are screwed into tapped holes on the sides of the two upright pipes, which holes are also tinned or soldered. He then applies a trough for conducting water over these tubes in small streams, so that the evaporation of the water may keep the pipes sufficiently cool to condense the steam inside. In applying the condenser to a steam engine, one of the upright pipes is connected to the eduction pipe of the engine, while the other upright pipe is connected to the air-pump. *Patent completed.*

2125. J. JOHNSON. *Improvements in machinery or apparatus for washing, churning, colour-mixing, or similar purposes.* Dated Sept. 22, 1858.

The inventor places the peggy in the ordinary tub, and gives to it a to and fro curvilinear motion by placing its rod or shaft in the boss of a bevel wheel geared into another bevel wheel, which has an alternate curvilinear motion imparted to it by fixing on its shaft a lever, having a stud placed in a slot of one of the arms of a double lever working on a fixed stud, the other arm being connected by a rod to a crank pin or a toothed or other wheel, having motion given to it by gearing pulleys or other suitable pulleys. The shaft of the peggy moves to and fro, and also up and down, as required, by means of a key and slot in the bevel wheel placed upon it. *Patent abandoned.*

2126. T. B. HUBBELL. *An improvement in hooped petticoats.* (A communication.) Dated September 22, 1858.

Here eyelet-holes are formed above and below one, two, three, or more of the upper hoops in the horizontal tapes or webs, whereby the hoops are held together, and it will be found convenient to form these eyelet-holes in, say, the third tapes from the front. A lace is passed through and through these eyelets from one side web to the other, and when the petticoat is on the wearer the lace is passed behind and the ends brought round in front; by tightening the lace to the extent required the desired fulness will be obtained behind, and the petticoat will sit neatly and flatly over the stomach. *Patent abandoned.*

2127. J. HOPE. *An improved calico printing roller.* Dated Sept. 22, 1858.

This invention is not described apart from the drawings. *Patent completed.*

2128. F. F. EMERY. *An improved sewing machine.* (A communication.) Dated Sept. 22, 1858.

This consists in a mode of operating the hook about the bobbin, viz., with a compound motion produced by a crank and an arm, or by two cranks, whereby the point of the hook is made to travel either in an elliptical or a circular path, without being reversed or made to point upward and downward during its rotation. Also, in an arrangement of a back supporter and loop cast off separate from the hook, so as to operate with the said hook and the front supporter or nipper of the bobbin in a manner not only to support the bobbin, but to aid in discharging a loop from the hook. Also, in an arrangement of a guide lip to the back supporter. Also, in an arrangement of an auxiliary presser or spring with respect to the bobbin and its holder. Also, in a mode of constructing the hook. The invention is not described in detail apart from the drawings. *Patent completed.*

2129. T. HOWE. *Improvements in smiths' forges.* Dated Sept. 22, 1858.

This relates to portable and stationary forges, and consists in constructing cylindrical or other forms of metal vessels, sliding or moving one within the other, and fitted with valves for the admission of air at the atmospheric pressure, and for its escape at the degree of pressure which

Digitized by Google

may be required. These are substituted for the ordinary leather bellows. *Patent completed.*

2130. R. A. BROOMAN. *Improvements in apparatus for printing shawls and other articles.* (A communication.) Dated September 22, 1858.

Here impression tables and colouring tables are employed, one or more tables being fixed, and one or more moveable. The moveable tables are each supported upon a horizontal frame or platform which rests upon rollers carried at the extremities of levers. These levers are mounted eccentrically upon centres, and have their opposite extremities connected by links to other levers, which are again connected by levers to the end or ends of a beam or beams. When this beam or these beams is or are caused to rock by a hand lever or otherwise, the several links and levers impart an upward or downward motion to the platform or frame, and through it to the table, the motion being rendered smooth and easy by the rollers on which the platform immediately rests. The printing blocks are supported upon wheels which run on rails, and are successively passed over the colouring tables and the impression tables, which are successively forced up to them by the parts before described. Provision is made for fixing the printing surfaces before the shawl, &c., extended upon the impression table is brought up against it, and also for adjusting the shawl, and bringing the desired portions of it successively beneath the same printing surface. When the colouring table is fixed a colour roller is connected to it, and arranged so that it will turn when the printing surface moves over it in one direction, and remain at rest when that surface moves over it in the opposite direction. *Patent completed.*

2131. J. TYSSEN. *An improved apparatus for indicating the speed of ships and other vessels.* Dated Sept. 22, 1858.

This consists of an apparatus to be fitted to a ship to show inboard the speed at which the ship is passing through the water. The inventor fits on the axis of a three-bladed screw, which is placed outside the vessel, a wheel inboard, which wheel gears into one or more wheels, and causes the last in a train to make, say, one revolution when the vessel is progressing at a certain rate, say ten knots an hour, which revolution is shown upon an indicating dial.—*Patent abandoned.*

2132. C. W. HARRISON. *Improvements in filters for purifying air and liquids.* Dated September 22, 1858.

This consists in arrangements for purifying air and liquids by the agency of carbon. *Patent abandoned.*

2133. L. CASTELAIN. *Converting all vegetable fibre by aid of chemicals into form to resemble horsehair.* Dated September 22, 1858.

The chemicals used for the above purpose are liquid chlorid, chlorid of gaz, chlorid of lime, soda, and sulphate of iron. *Patent abandoned.*

2134. J. SPENCE. *Improvements in the manufacture of steel, and in the furnaces employed in such manufacture.* Dated September 22, 1858.

This consists, 1, in producing steel from pig-iron or other cast iron in a puddling furnace, by regulating the quality or chemical condition of the air passed into the furnace. 2, in an improvement in the puddling furnace, whereby each regulation is effected. We have given a detailed description of this invention on page 302. *Patent completed.*

2135. A. B. CHILDS. *Improvements in winnowing machinery.* Dated September 22, 1858.

Here the foul corn or grain is placed in a hopper, which has a long narrow opening at the bottom, so as to divide the corn or grain into a thin stream, which in descending meets with streams of air from a fan, by which much of the chaff, &c., is blown forward through a spout, and then the corn or grain falls on to a riddle or screen of sheet metal, the holes in which are of a size large enough to let the sound grains of wheat or grain pass through, but prevent the chaff and substances which are lighter, and also those which are larger, passing through, and such substances move on and are passed off at the front end of the machine, which is facilitated by a stream of air coming from the same fan as that from which the upper blast is derived, passing under and rising up through the holes in the riddle. The holes in the riddle are punched so as to produce a raised margin to each hole on the upper surface of the riddle. From the riddle the grain and seeds which have passed through receive a second winnowing, and descend on to an inclined screen, the holes of which are of such size as not to permit the sound grains of corn or grain to pass through, but allow seeds and the matters or substances less than the sound grain to pass through, and these matters fall on to and descend down an incline below the screen into a receiver at the bottom. *Patent completed.*

2136. EARL OF DUNDONALD. *An improved machine or apparatus for tilling and preparing land for cultivation.* Dated September 23, 1858.

Here a series of spades, prongs, cutters, &c., are caused to revolve on an axis driven by wheels and pinions or endless bands, from the supporting or carrying wheels of the machine or their axis, the contact of the periphery of the wheels with the ground producing the movement of the cutter frame. The mechanical movement which actuates the cutter frame is so proportioned as to give a relatively increased velocity to the spades or tilling instruments. By these means the tilling instruments are made to move the ground at a greater velocity than that at which the machine advances and at a favourable angle for penetrating the soil. *Patent abandoned.*

2137. A. F. JALOUREAU. *Improvements in the manufacture of pipes.* Dated Sept. 23, 1858.

This consists in making water or gas pipes, or pipes for enclosing electric telegraph wires, by rolling up in a cylindrical form thin sheets of paper, cloth, wire-gauze, metal, &c., which are cemented or soldered together by a waterproof cement or material. *Patent completed.*

2138. H. MCGRADY. *Improvements in the construction of flues, boiler and other furnaces, and in certain appliances thereto.* Dated September 23, 1858.

Here the inventor forms a bridge at the extreme end of the furnace, which may be called the flame-bridge; nearer the furnace mouth is another bridge perforated with a number of ports or passages through which the flame rushes; a third bridge stands a little way from the last-mentioned one, nearer to the furnace mouth, which may be called the fire-bridge, over which the flame plays in passing through the port-bridge. Passing across the front of the furnace mouth, under the plate, is a tube or pipe fixed transversely to the direction of the furnace, and having a number of small apertures which are opened and closed by a shutter. This tube, bending in a direction perpendicularly to its length, opens into and is connected at each end with two other tubes which pass alongside the furnace, and terminate each in a chamber beyond the flame-bridge, so that when the apertures of the front tube are open, the air rushing in will pass along the last-mentioned two tubes, and discharge itself into the flame at the flame-bridge. *Patent abandoned.*

2139. T. C. HINDE. *An improvement or improvements in the manufacture of iron and steel.* Dated September 23, 1858.

This consists in the use of hydro-chloric or muriatic acid or sulphuric acid, or nitric acid, applied in admixture with common salt or other analogous compound, the said mixture of acid and salt being mixed with the fused cast iron. *Patent completed.*

2140. D. GRANT. *Improvements in colour-printing presses.* Dated September 23, 1858.

This consists in making use of a circular bed upon which the blocks from which the printing is to be taken are placed, and for as many blocks as there are upon the bed the patentee arranges round the press inking-apparatuses, one for each block; each inking-apparatus is intended to supply ink of a different colour. Motion is communicated to each inking-apparatus to cause that part which supplies the colour to the block to travel over the block and back by a cam or eccentric worked by a pinion set in motion by a toothed-wheel or rack extending round the press. The tympan is circular with flaps in two compartments, and upon rotary motion being communicated thereto, it carries the paper successively over each block; the platten descends once for every successive onward motion of the tympan. The invention is not fully described apart from the drawings. *Patent completed.*

2141. J. WILSON. *Improvements in floating docks.* Dated September 23, 1858.

Here a floating vessel is constructed with parallel upright sides, the ends being at right angles to the sides, or otherwise, there being a grate or grates at one of the ends. The sides are each made hollow, with upright partitions, to separate the space between the two walls of each of the sides into several compartments. Provision is made for communications or water-ways being opened from one compartment to another. The upper compartments on each side are divided by one or more horizontal partitition, the upper horizontal partition on each side forming the floor for an engine-room and workshops. A steam-engine, or engines and boilers, with suitable pumps, are to be erected in each of the sides of the dock, with apparatus for steaming timber, the engines also working the sawing and other machinery in the workshops and dock when not used for the purposes of the dock. One end of the dock is also constructed hollow and divided into compartments, with water-passages and valves, so as thereby to be enabled to adjust the level of the bottom, notwithstanding an excess of weight being at any time at one end of the dock. There are other modifications. *Patent completed.*

2142. P. PICKERING. *An atmospheric engine.* Dated September 24, 1858.

This invention is not described apart from the drawings. *Patent abandoned.*

2143. R. and W. FORD. *Smoke consuming by means of a reciprocating or reversing fire.* Dated Sept. 24, 1858.

Here the furnace is divided into two compartments by a partition. This partition is placed on the level with the grate or bars of the furnace, reaching up to and touching the bottom surface of the boiler. In this partition a passage is left to allow the smoke to pass from one compartment to the other. The passage is close to the front of the furnace at the back of the furnace door, and the lower surface thereof is on a level with the bars. Each compartment has a separate furnace and damper at the back end of the grates. At the opening left in the partition, provision is made for the admission of atmospheric air from below, by small bars or a perforated plate. The supply of air is regulated by a shutter underneath. The furnaces are charged alternately, and the damper in connection with the chamber into which the fresh coal is introduced is shut down, thereby preventing the escape of smoke to the chimney. The smoke or gases emitted or generated from the fresh or green coal are retarded on the way into the other fireplace by the size of the opening in the division wall, and from confinement to an extent in the furnace attain the necessary temperature, which compels the gases to unite, and gradually lessens the bulk of the smoke, which, as it now moves through the opening in the partition, is mixed with a quantity of atmospheric air, when it ignites and passes over the other fire, burning with great rapidity, and yields a large extent of heating power. The consuming of the smoke is thereby completely obtained. *Patent abandoned.*

2144. E. T. WRIGHT. *A new or improved method of, and apparatus for, preventing the explosion of, or injury to steam boilers through deficiency of water.* Dated Sept. 24, 1858.

This consists in connecting a water buoy or float in the steam boiler with the furnace door, or with a door opening into the furnace, so that when the water in the boiler falls below a given level, the said door is opened. By the opening of the said door cold air is admitted into the furnace, whereby the boiler is cooled, and the draught through the fire to a great extent suspended. This invention is not completely described apart from the drawings. *Patent completed.*

2145. R. A. BROOMAN. *Improvements in the manufacture of pile and cut pile fabrics, and in machinery employed therein.* (A communication.) Dated September 24, 1858.

This consists in the manufacture of a new kind of pile fabrics, particularly carpets, whereby designs in all colours may be produced with great sharpness and distinctness whatever the length of pile. The machinery consists of a very simple loom. The most important feature in the manufacture is the arranging of the warp. The invention is not described apart from the drawings. *Patent completed.*

2146. H. H. and W. F. HENSON. *Improvements in water-proofing leather, woven fabrics, and other materials, and also for rendering them fire-proof, or partially fire-proof.* Dated September 24, 1858.

Here the materials are passed through a solution of chloride of zinc, and then through a mixture of solutions of hydrated protoxide of lead and sulphate or acetate of alumina, or both. The patentees also use a mixture of solutions of nitrate of lead, acetate of lead, and sulphate of alumina. *Patent completed.*

2147. R. BODMER. *An improved apparatus for preventing explosion in steam boilers.* (A communication.) Dated September 24, 1858.

This consists in the adaptation of a tube made of copper and of sufficient length to give the requisite amount of expansion necessary to actuate a depressing lever when the escape valve requires to be opened. *Patent completed.*

2148. C. F. VASSEROT. *Improvements in the construction of spinning cards.* (A communication.) Dated Sept. 24, 1858.

This relates to the manufacture of cards, the teeth of which are kept by their basis, and strengthened at the back by cloth or leather. The card has its fixed basis stuffed with fleece wool. The part adjoining the fixed part is formed of a piece of felt, coated before the teeth are put in with gutta percha. This felt must be sufficiently soft to allow the teeth to spring; joined to this latter, so as to make one body, is a box coated with gutta-percha, and in the front of this is a piece of cloth of the usual form. *Patent abandoned.*

2149. W. RICHARDS. *Improvements in fire-arms and cartridges.* Dated Sept. 24, 1858.

Here, in making breech-loading fire-arms wherein plugs or moveable pieces are used to close the breech ends, the patentee applies to such plugs or moving pieces hooks or instruments which enter into and hold wads or parts at the back ends of the cartridges, so that when the plugs or moveable pieces are moved back to admit of fresh charges being introduced at the breech-ends of the fire-arms, the hooks or instruments may withdraw the wads or exploded cartridges. The arrangement of plugs or sliding-pieces for the closing of the breech-ends of fire-arms which he prefers when using this part of his invention, is that described in the specification of his former patent dated the 25th of March, 1858. *Patent completed.*

2150. G. L. FULLER. *Improvements in steam-engines.* Dated Sept. 24, 1858.

This consists in such a combination of steam-chests or passages and steam valves as to enable two or more cylinders, working at different angles to one another, to be worked as may be required, either jointly at their full powers or on the continuous expansion system, wherein the steam admitted to the first of the series afterwards forms the supply to the others, thus giving to two or more cylinders, so arranged, as extensive a power (or nearly so) of expansion as could be attained in a single cylinder with a stroke equal in length to the sum of the strokes of such cylinder, and at the same time leaving their joint actual power intact. And the invention consists mainly in forming separate, or dividing the steam passages or chests for the valve openings to the tops and bottoms of such cylinders individually, but common as regards the tops and bottoms of the series respectively, and then arranging an expansion valve or valves common to the whole to govern the whole supply. It also consists in working the above expansion valve or valves, so as to render the same applicable to the purpose required, by enabling the cutting off of the steam from the different ends of the cylinders to be independent, and thus to permit of the rate of expansion being extensively varied while the engine is at work. *Patent completed.*

2151. G. L. TURNEY. *An improved mode of packing pins for sale.* Dated Sept. 24, 1858.

The patentee forms a kind of book consisting of a cover containing leaves of paper for receiving each a row of pins, and into these leaves he inserts the pins in the usual way of sticking pins into paper. *Patent completed.*

2152. A. F. DELACROIX. *Improvements in locomotive engines.* Dated Sept. 25, 1858.

These consist, 1, of a new system of transmitting the movement of the steam cylinder piston to the driving-wheels; 2, a particular system of brakes permitting the stopping of a train of carriages without shock at the third or fourth turn of the wheel. These features are not described in detail apart from the drawings. *Patent abandoned.*

2153. R. ROMAINE. *Improvements in the construction of steam cultivators, and in the means for operating such and other locomotive steam engines.* Dated Sept. 25, 1858.

This relates, 1, to various improvements in the details of construction of the cultivators for which the patentee has obtained letters patent; and, 2, to means of facilitating the working of such machines, and the turning of traction engines generally. The invention is not described apart from the drawings. *Patent completed.*

2154. M. A. F. MENNONS. *The separation of iron and steel from their combination with certain foreign bodies.* Dated Sept. 25, 1858.

This consists in economising the waste matters known as "grindstone sands." The oxides and earthy parts of this waste material being separated, the residue, which is composed of finely-divided iron or steel, is submitted to pressure for the double purpose of expelling the moisture and giving a certain amount of cohesion to the mass. The metal is then passed to the furnace and is either forged

Digitized by Google

directly or reduced to castings in the ordinary way. *Patent completed.*

2155. E. FARNCOMB. *Improvements in Lilliputian fire-arms.* Dated Sept. 25, 1858.

This applies to Lilliputian or toy fire-arms, and consists of various arrangements of detail to be used with very small percussion caps, and very small charges of gunpowder. *Patent abandoned.*

2156. C. HALL. *Improvements in apparatus for applying power to the cultivation of the soil.* Dated Sept. 25, 1858.

This invention was described and illustrated at page 218, No. 14, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2157. W. CLARK. *Improvements in purifying natural phosphates of lime.* (A communication.) Dated Sept. 25, 1858.

This consists, 1, in the purification of phosphates of lime for rendering them easier of transportation and assortment, by treating them with an acid, such as hydro-chloric acid, for eliminating the carbonates combined therewith; 2, in the purification of phosphates charged with silica or silicates, by agitating them in water, for precipitating the silica, and then decanting the muddy liquid which contains the phosphate of lime in a pure state, as described; 3, drying phosphates of lime purified in a stove, or in drying turbines or machines. *Patent completed.*

2158. J. C. DIEULAFAIT. *A kind of garment which may receive different forms according to the will of the wearer.* Dated Sept. 25, 1858.

This consists in making garments so that their shape may be changed or modified at will. *Patent abandoned.*

2159. S. H. GREAVES. *Improvements in the mode of manufacturing the blades of table and other knives.* Dated Sept. 27, 1858.

This consists in cutting the bar steel into short lengths, and before reducing it to shape, welding it to the iron which forms the bolster. The blade and tang are then drawn out, and the knife finished in the usual way. *Patent abandoned.*

2160. X. BOUTTEVILLE. *An improved neckcloth or tie, means of connecting ties to collars and bands, and an improved collar.* (A communication). Dated Sept. 27, 1858.

This consists of a band or collar, the ends of which are brought round to the front of the neck, and terminate in two loops, by preference of metal, which loops are attached to the band or collar. The tie or band which is used to form the bow consists of a strip of silk, &c., sufficiently long to form the bow or knot; it is passed through the two loops, and the ends brought back to tie the bow or knot. *Patent abandoned.*

2161. W. LANDER. *Improvements in engraving and printing for the purpose of ornamenting china and earthenware.* Dated Sept. 27, 1858.

This invention was described and illustrated at page 231, No. 15, of the MECHANICS' MAGAZINE (New Series). *Patent completed.*

2162. E. L. BENZON. *Improvements in the manufacture of steel.* (A communication.) Dated Sept. 27, 1858.

The patentee introduces into a reverbatory furnace crude pig iron, or refined metal, and in the first stage of the puddling process adopts the usual mode of operation, to bring the mass to a perfect state of boiling. He then makes up a good fire, and works with an open damper, to accumulate sufficient heat for subsequent operations. During the boiling and raising of the mass, globular grains begin to appear on the surface of the melted cinder, and these will increase gradually in number as the process continues. The elimination of the mechanically-combined carbon goes on very rapidly. As the decarbonisation continues, the grains will become pointed, and even elongated, and on touching each other, will now adhere, and, on uniting, will sink through the cylinder. This will indicate the presence of that percentage of carbon which constitutes the hardest weldable steel. This stage of the process having been attained, will form a starting point for the workman, and will enable him to produce steel of the different degrees of temper and hardness required for various applications and purposes. As soon as the proper amount of decarbonisation has been effected, and the further progress thereof stopped, the metal is to be formed into balls, care being taken always to keep the metal as much as possible immersed in or covered by the cinder, and when the balls are made, they must be removed from the furnace, and forged into blooms at the welding heat of steel. *Patent completed.*

2163. W. E. NEWTON. *Improvements in cigar holders, or mouth pieces for cigars, and in pipes for smoking tobacco.* (A communication.) Dated Sept. 27, 1858.

This consists in placing a chamber or bulb in the cigar-holder, between the cigar end of the cigar-holder, or the bowl of the pipe and the mouth-piece, and fitting into the bulb or chamber a piece of sponge, &c., to absorb and hold water, so that the sponge, &c., will pretty accurately fit the chamber or bulb, allowing the smoke to pass through the sponge, &c., and arresting and absorbing the empyreumatic oil arising from the burning tobacco, and at the same time cooling the smoke as it passes through; and in addition in placing a diaphragm filter across the bulb. *Patent abandoned.*

2164. E. LEWTHWAITE, and G. AMBLER. *Improvements in clocks, watches, chronometers, and other time-pieces.* Dated September 28, 1858.

This relates, 1, to the escapement, and consists in dispensing with the "pallet-wheel," and substituting in lieu thereof a "propeller" made of metal, stone, &c., with one or more very short arms, pins, or radii, which act upon the pallet as a "dead-beat," or otherwise. By this the inventor avoids the variations in time caused by the changes of temperature expanding and contracting the pallet-wheel. It relates, 2, to the fusee, and consists in having the driver, or first motion-wheel, formed with inverted cogs, in addition to the cogs now thereon, such wheel to be loose upon the axis, or spindle of the fusee, and gearing with a small pinion working in a stud attached to the fusee, which gears with a pinion affixed on the axis or spindle. By this means power or continuous action is maintained whilst winding-up. *Patent abandoned.*

2165. B. JONES. *Improvements in press wheel rollers, or clod crushers, which improvements are also applicable to rollers for crushing, bruising, and pulverising roots, and other substances.* Dated September 28, 1858.

Here two or more external rollers working in the same plane are fitted with internal rollers to correspond, the external rollers being formed with blades of hammered iron. When the rollers are set in motion, the internal rollers fit into the interstices between the blades, and are carried round in a direction contrary to that of the external rollers. The earth is thus prevented from adhering to the blades of the roller. *Patent completed.*

2166. J. H. LINSEY. *Certain improvements in binding or covering books.* Dated September 28, 1858.

This invention was described and illustrated at page 240, No. 15, of the MECHANICS' MAGAZINE (New Series). *Patent abandoned.*

2167. G. MEAD. *Improvements in the construction of tobacco pipes.* Dated September 28, 1858.

Here the bowl of the pipe has an internal reservoir for the reception of tobacco, communicating by a suitable aperture at the lower part thereof with a chamber at the bottom of the bowl, the chamber extending also between the internal surface of the bowl and the exterior of the reservoir, which latter is united to the bowl at the upper part thereof. The pipe or tube is so placed as to open into the upper part of the chamber between the bowl and the internal reservoir, the effect being that the oil descends through the aperture in the reservoir containing it into the lower part of the chamber, when the oil will be absorbed by the bowl, colouring the latter, and rendering the smoke cool and agreeable. *Patent abandoned.*

2168. J. L. CLARK. *Improvements in coiling and securing telegraph cables preparatory to laying them from ships or vessels.* Dated September 28, 1858.

In coiling an electric telegraph cable into the hold of a ship, strong cords or bands are used at intervals around the coils. The one end of each cord or band is to be made fast, and a loop is to be made therein, and such loop is to embrace a coil of the cable; then another loop is to be drawn through the previous one, and such loop is to embrace the next coil of the cable; then another loop is to be drawn through the previous one, which is to embrace the next coil of the cable, and in this manner each coil is to be embraced by a loop formed in each of the cords or bands, and so long as the last end of each cord or band is retained the loops will hold the coils securely together; but as the ends of the cords or bands are pulled, the succeeding loops formed in the length of the cord or band will be released, and the coils will be successively unlashed one from another. *Patent abandoned.*

2169. J. MANNING and T. PAUL. *An improved stone staff to be used in dressing millstones.* Dated Sept. 29, 1858.

This stone staff is more particularly adapted to "staffing" mill-stones. The staff is supported upon two metal discs, which rest one upon the other, the surfaces in contact with the discs being perfectly true. The upper disc carries the staff itself, with which it is made to revolve, so as to pass over the whole surface of the mill-stone in a true plane. It is, therefore, impossible that the face of the staff can touch, and consequently it cannot mark any other than the highest places on the millstone. These places, when indicated by the staff, are afterwards removed with the "stone-bill" in the ordinary way, and the process of marking and removing the projecting places is repeated until the whole surface is made perfectly true. *Patent completed.*

2170. J. LUIS. *A new method of fixing pastel pictures.* (A communication.) Dated September 29, 1858.

Here the pastel picture is executed in the ordinary manner, care being taken not to use unpasted paper, the thick printing paper for copper plates being best. On a smooth marble or wood slab a layer of almost liquid silicate of potash, or natron, about one-fifth of an inch in thickness, is spread. The back of the pastel picture is then placed upon the silicate surface, so that the liquid may be absorbed through the back of the paper. When the picture is well saturated, it is held so that the superfluous liquid may run off; after that the picture must be placed upon a paper to dry. This operation is repeated, and the picture is completely fixed. *Patent abandoned.*

2171. G. OLD and T. PENDLETON. *Improvements in dress fastenings, and in attaching dress-fastenings to articles of dress.* Dated September 29, 1858.

This consists of two pieces of sheet metal, each having a form resembling an anchor. The arms of one part of the fastening are bent a little upwards, and the arms of the other part are bent a little downwards out of the plane of the sheet metal of which they are made. When the parts are attached to the parts of dress, &c., to be fastened, the arms of one part may be engaged with, or hooked to the arms of the other part, and the two portions of the dress be held thereby together. There are modifications included. *Patent abandoned.*

2172. G. T. BOUSFIELD. *Improvements in apparatus for, and in the manufacture of paper bags, and other similar articles.* (A communication.) Dated September 29, 1858.

This consists in drawing a continuous sheet of paper (from a roll) around a rigid bar or former, pasting one edge of the paper, and pressing the other edge upon the pasted edge, so as to form a partially flattened tube. *Patent completed.*

2173. T. BRITT. *An improvement in the propelling of steam-boats.* Dated September 30, 1858.

This consists in the construction of a folding four-blade propeller, and the shafting for the same. This propeller is formed by four blades coupled together by a joint in the boss of the propeller. The two principal blades have the bearings. The centre part of the boss is taken out half-way along the boss, sufficient metal in the thick part of the blades to answer for the centre of the boss being taken out of the other two blades. The boss is taken out half-way along; it goes in the boss of the two principal blades, and the after-bearing is bolted on the two principal blades. In the two principal blades the fore-part of the boss is hollow. The shaft goes through that part to work the two centre blades; thus the joint is formed in the boss of the propeller. The object of this joint in the boss of the propeller is that it allows the propeller to close together, or open-out at right angles, as may be required, for the convenience of lowering the propeller down in its place, or hoisting it upon deck. When the propeller is down in its place, there are apparatus to open them out at right angles, and the shaft is made to couple them in that position, and work them in that position. *Patent completed.*

2174. J. WRIGHT. *Certain improvements in the mode of arranging and moving fire-bars for locomotive, puddling, and other furnaces.* Dated Sept. 30, 1858.

This consists, 1, in the mode of arranging fire-bars of furnaces in such a way that by acting on the alternate ends of a set or series of such bars they shall be raised or lowered in contrary directions. 2. In having the top edges of the bars of any regular or irregular form, and so arranging them that they shall possess a horizontal reciprocating motion, that is to say, that while one portion are receding from the mouth of the furnace the other portion advance towards the mouth, and at the same time the latter are coming forward they may be also elevated. *Patent completed.*

2175. J. MORRISON. *An improvement in or addition to sewing machines.* Dated Sept. 30, 1858.

This consists of an instrument to be attached to sewing machines for folding the edges of the fabric to be sewn, consisting essentially of two plates or strips of sheet metal, or one plate folded, the said plates or strips being situated parallel to one another, twisted into a screw-like form, and either grooved or plain on their inner or opposed surfaces. *Patent completed.*

2176. S. TAYLOR. *Certain improvements in apparatus to be used as a fire-escape, which improvements are also applicable to other similar purposes.* Dated September 30, 1858.

This consists in the use of a well-known arrangement or system of levers, which when suitably hinged and jointed are commonly called "lazy tongs." *Patent abandoned.*

2177. L. CECCONI. *Improvements in the construction of cornets, trumpets, horns, and other wind instruments of a like nature.* Dated September 30, 1858.

This invention was described at page 240, No. 15, of the MECHANICS' MAGAZINE. (New Series.) *Patent completed.*

2178. H. KINSEY, W. H. MORRISON, and S. SMITHARD. *Improvements in means or apparatus for the purpose of folding lace or other fabric, and also for cutting the same into lengths adapted to be used in the manufacture of bonnet and cap fronts, and for other purposes of millinery.* Dated September 30, 1858.

Here one end of the fabric to be folded is passed in between the parts of a plate or trough, the sides or opposite edges of which gradually incline towards or over one another, with a tendency to cause the edges of the fabric passed therethrough to fold in the direction desired. And one end of the fabric having been passed into such first folding means it is thence taken hold of by rollers in pairs, which act not only to draw the fabric through such first folding means, but also to flatten or fully crease the folded parts. In connection with rollers other rubbing surfaces may also be employed, as may also steam or other heat to such rollers or rubbing surfaces. The fabric thus folded with its two edges towards or over the centre thereof is then passed between other guides, having a tendency to cause it to fold again in the middle, and through this second folding means the fabric is drawn by other rollers to flatten it, and through other flattening means if desired to produce a perfect creasing to the fold obtained. The inventors also apply in connection with such folding means cutting apparatus governed to act at intervals desired, so as to cut the fabric into requisite lengths. *Patent abandoned.*

2179. R. LEVY. *Improvements in the manufacture of coats, ladies' riding habits, and other similar garments.* Dated September 30, 1858.

The inventor places under the arm pits or other parts a number of eyelet holes or ventilators to remove the excess of heat, and prevent excessive perspiration. *Patent abandoned.*

2180. C. W. SIEMENS. *Improvements in electric telegraphs.* (Party a communication.) Dated Sept. 30, 1858.

The specification of this invention contains a great amount of detail, and is too voluminous to admit of an intelligible abstract in our pages. *Patent abandoned.*

2181. A. NORMAND. *Improvements in constructing ships and vessels propelled by screw or such like propellers.* Dated Sept. 30, 1858.

Here the patentee gives to the part of the stern comprised between the two stern posts on each side of the central plan of the vessel, and on a proper extent, a segmental form, either convex or concave in cross section, or a plane surface. He closes the bottom opening of the well-hole by sliding lateral doors or shutters taking the form of the outside of the vessel and moveable either from within or from the deck of the vessel, so as to recede or approach each other. He also proposes to alter the usual shape of the opening of the well-hole, making it follow the profile figure of the screw when viewed from the stern, the screw being turned to bring the central part of its blades into a vertical line, which is the position it will be required to take when it is raised or lowered.—*Patent completed.*

2182. G. UHLHORN. *Improvements in applying motive power to give motion to machinery.* Dated Sept. 30, 1858.

This is applicable where two or more prime movers are employed to give motion to the same shaft, and the invention consists in so connecting together the shaft from the two or more prime movers that the shaft from the prime mover of the greatest power will not in rotating cause the shaft from the prime mover of lesser power to rotate, but the shafts from the prime mover of lesser power will, in rotating, cause the shaft from the prime mover of greater power to rotate. *Patent completed.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, MAY 13, 1859.

THE WAR RESOURCES OF ENGLAND.

"There is a sound of thunder afar,
Storm in the South that darkens the day,
Storm of battle and thunder of war,
Well, if it do not roll our way."
"T." in the *Times*.

THERE is no beauty in war that we should desire it; and, happily for us, we have lived to see England stand firm in a peaceful neutrality while continental emperors take each other by the beard. It will indeed be well if the storm "do not roll our way." It may, however; and lest it should we must prepare to sustain it. This is the feeling of the nation, and this is the meaning of that summons of the Poet Laureate's (if we mistake not)—

"Form! form! riflemen form!
Ready, be ready to meet the storm!
Riflemen, riflemen, riflemen form!"

The poet is justly impetuous, and his energy is not altogether misdirected in calling upon small-arms'-men to "look to their butts and take good aims." But his cry, and a thousand other cries of like nature, just now raise again the question, How far the existing appliances of warfare ought to be relied upon by England in this day?

War is unquestionably a barbarous pursuit. It is, we doubt not, destined to ultimate, although remote extinction. We believe that—as Mr. Buckle states in his magnificent "History of Civilisation"—every great increase in the activity of the human intellect has been a heavy blow to the warlike spirit; and that—as Sir Benjamin Brodie lately remarked at the Royal Society—there are very few of the discoveries which have been made in the physical sciences which have not, sooner or later, had the effect of promoting the well-being of mankind, in this respect. We may therefore reasonably anticipate a period in the history of human civilisation when men shall really beat their swords and spears into ploughshares and pruning-hooks—when future Mechis and Fowlers shall buy up the stocks of the Lancasters and Wilkinsons.

But meanwhile we *may*, as we have said, have to fight; and it is very important that we should know how to do that in the most effectual manner. Up to the present moment we are relying solely upon instruments and munitions of warfare which, so far as their leading qualities are concerned, have become old and universal. We thrust at the enemy with bayonets; we slash at him with swords; we let off pyrotechnic tubes at him; we blow little balls of lead and large balls of iron at him; and we sometimes make the balls of iron hollow, and put a combustible substance inside them. This is the sum of our warlike operations. We are improving the details of the various instruments used for these purposes it is true; but that is all. Sir William Armstrong's gun is, at the very best, only a means of throwing bolts and balls with greater accuracy, and to greater distances, than heretofore. No one can pretend that it is more. And yet that gun—which others already possess as well as ourselves—is the only improved weapon of offence that we are arming ourselves with for coming eventualities. And in respect of our defence, the expedient of covering the sides of ships with shell-proof iron—an expedient which the Admiralty have only *talked about* as yet, and which, however necessary, is after all a clumsy kind of business—is the only novelty we contemplate.

Now, this is not, in our judgment, as it ought to be. Science can befriend us in other and better ways than these; and we have no right to turn from her advances. She can enable us to broaden, and deepen, and heighten, and quicken our powers of hostility. There is—to go no further for an example—the Macintosh system, which cabinet ministers have inquired into, and witnessed, and trembled at, and tried to suppress, but which they have neither the courage to sanction nor the sagacity to adopt. Its efficacy is not, we believe, doubted; at any rate it has been tested officially more than once but never reported against, and if past experiments are deemed insufficient, the inventor is ready to repeat his proceedings at any place, on any scale, and in the presence of any appointed functionaries, at his own cost. And assuming (as we have therefore the right to assume) its efficacy, its power would make us most terrible. Masters of the seas as we are, there is not a sea fortress on the continent which it would not put safely, cheaply, and bloodlessly into our hands, should the need for taking it arise. There is no harbour that could hold an enemy secure from us. At the same time the system of warfare under notice is not necessarily destructive; it may be used simply to render innoxious—to *disarm*, as it were—the enemy if desired. "It is surely time," as we said on a former occasion, "for the country to inquire how it is that such an invention is not favoured by the guardians of the State. There is nothing secret, nothing illegitimate, nothing suspicious about it; the inventor has published his plans, courted investigation, and even invested much money in furtherance of his invention; there can be nothing absurd or preposterous in his proposals, for Lord Panmure took pains to keep them secret during the war, and thus pronounced even more strongly in their favour than if he had consented to adopt them. We have never yet known a word to proceed from any other official person against them; there is considerable anxiety in the nation respecting our defences; and Members of Parliament are threatening to tax us even yet more heavily in order to increase them. There can, therefore, be no good, no plausible reason, even for delay, and indecision, and circumlocution in the matter. The public should see that the invention is no longer neglected. They should also see that a better spirit is introduced into our War Department. It will not do for us to plod heedlessly on in this art of war, which we are so well able to improve."

As a matter of economy, this subject should be looked into, and studied, and pronounced upon by the nation. It cannot be denied that the existing systems of warfare are extravagantly costly. Let us take an illustration of this. In the naval attack upon Sebastopol, on the 17th of October, 1854, the Agamemnon and Sans-pareil were stationed at 800 yards from Fort Constantine. These two ships could bring about eighty-seven guns to bear upon the works, and the firing from them lasted four hours; yet the strength of the masonry of the fortress was not at all impaired! It has been estimated that some 7,700 shot and shell were fired; and since the effects produced were comparatively slight, most of this number must have been uselessly expended. Again, when the large Russian steamship Vladimir was fired upon by expert gunners, in the most deliberate manner, at a distance of twenty-five cables' length only, she was struck by only 10 shots out of 500! These facts indicate, however faintly, somewhat of the extravagant expenditure of means and money which is contingent upon the present modes of warfare.

It is high time, therefore, that we supplemented our present practice by something cheaper, more simple, and more effective. It is folly to shut our eyes and ears either to the defects of our present means, or to the practicability of improving and adding to them. And this, if ever, is the time to give the subject our attention. Our aim is to remain neutral and inoffensive, but our desire is to be strong as well as pacific; and while we contemplate nothing but self-defence, we are bound to perfect that defence by the readiest and best means at our command. It remains, therefore, for the nation to say whether, in the event of another war, we shall content ourselves with repeating the ineffective display made during the last war in the Russian waters, or whether we shall invest our fleets with such a power as that which the Macintosh system is admitted to possess.

EXPLOSION AT GUNPOWDER WORKS.

WE have to thank "Polvora" for the very temperate letter which appeared in our last number—temperate because "Polvora" evidently holds in his hands the artificial thunder which has sent so many of the innocent and guilty to perdition, and which he, as the champion of the gunpowder manufacturers, knows so well how to wield. The letter is, moreover, of value, as emanating from "the largest manufactory in England (perhaps in the world)."

Having, then, caught a gunpowder manufacturer, and one who "has not had *a fatal* (the italics are our own) accident for twenty years," we can do no other in courtesy than request him to accept our congratulations at so desirable a state of things in the district of his factory. In doing this, he must pardon us if we place him before his brethren as an example both to admire and to imitate. For has he not introduced and improved the machinery of the "mixing-houses," the "incorporating-mills," the "press-house," the "caming-house," the "drying-house," and the "dusting-house?" And "these," he *naively* adds, with a well-deserved "blow" at his brother manufacturers, "have not been *blazed* abroad to the world"—and, as a *non sequitur*—"there have been no fatal accidents." Are we, then—as he does not hint at what these improvements are—to conclude that secresy is a prevention, and that publicity is the cause of accidents? and are we likewise to conclude that it is only at ——— that these improvements in the machinery, and the consequent reduction of the number of hands, are to be found? If so, we at once enlist "Polvora" upon our side, and confidently appeal to our readers that so far from our strictures being "rather severe," they have not been strict enough. For where judicious thought and judgment have been exercised there, "no fatal accidents have occurred for twenty years." Then, say we to those who have turned their picturesque mills and grounds into slaughter-houses, "Go unto your neighbour, and profit by his council. Be thou no longer insensible to improvements, but learn wisdom and mercy in ———!" We may add, that we have heard the highest encomium passed upon the firm from which "Polvora" writes for their unselfish devotion to the welfare of their workpeople, and we can readily believe that the well-earned and merited payment he mentions is cheerfully accorded to men "amongst whom a case of drunkenness is never known;" and we are equally assured, from the most reliable source, that when the same firm thought they saw in the introduction of gun-cotton a less dangerous compound than gunpowder, they readily embarked a large fortune in it, and as conscientiously abandoned it with a heavy loss upon the discovery of their error in judgment.

But these are exceptional cases, and do not shake one jot the premises upon which we have taken our stand as a rule. We know full well that

Digitized by Google

the matter of wages is an irritating one, and as it may—indeed does—form a large element in the consideration of *safety*, we are not a little proud to add from so high an authority as "Polvora" —"Give men good wages, and you may generally get good men." Upon this point—the lowness of wages—"Polvora" "would fain hope there is some misinformation." *There is none.* Two and twopence a-day—and two and twopence only a-day—do the "black-men" get who are exposed in the mills to the first and worst consequences of an explosion. True, this amount before coroners' juries is made to assume a higher and less illiberal rate, by stating that "the 'black-men' can earn twenty-four or thirty shillings per week." But this is only done by over-work —by the sacrifice of two or more nights of rest —and by a consequent self-consignment to so many hours more of peril and risk.

It will thus be seen that "we do not grudge the manufacturers their due meed of praise" where praise is really due, and it would give us immeasurable satisfaction, even at this late hour to be shown that we were incorrect in our statements, and consequently to blame for our strictures. Nor do we "censure the manufacturers because they cannot cope with the elements;" but we certainly think that when the brewer, the home-made wine manufacturer, the vinegar maker, and the gin distiller, &c., have their practical and analytical chemist at their elbow, so treacherous a compound as gunpowder, (now —*only now*—discovered to be "not so simple in its elements as was formerly supposed, but can boast for its properties, besides the usual products of carbonic acid, carbonic oxide, nitrogen, and sulphide of potassium, the presence of hydrogen, oxides of nitrogen, cyanide of potassium, sulpho-cyanide of potassium, sulphate and carbonate of potash, and various other salts," the several quantities of which have been determined by Bunsen), ought not to be left without scientific espionage to watch its vagaries, and keep its dangerous idiosyncracies in check. Upon whom does the disgrace fall, if the men who accumulate large fortunes in its production, and ought to be the natural guardians of their assistants, are to be held immaculate and free from stricture?

THE ENGINES OF HER MAJESTY'S SHIPS OF WAR.

In returning to the Report on the Marine Engines of the Navy, to which we drew attention in our last number, we have to observe that the committee next directed their attention to the means that have been taken to preserve the engines and boilers of the vessels laid up in ordinary. On this subject, as on all others, the committee write with a solemn guardedness of language, which would have been very effective indeed if it had been associated with any researches or conclusions of importance, but which, as it is, looks very ridiculous, and only fails to be amusing because it is puerile. They think, for example, that steam-vessels of the first class —which are supposed to be ready for sea at twelve hours' notice—should not be taken on occasional trial trips, unless there be other than engineering reasons for the practice. And so with regard to the employment of the spare time of the steam-ship staff in ordinary, upon which they "twaddle"—(we dislike that word, but it expresses what we mean)—justifying their remarks by the sapient announcement that "nothing is trivial which conduces towards improving the system of public service." They conclude this part of their Report by making several recommendations, bearing mainly upon subjects discussed in our former article. Of these recommendations we shall here notice the first three only. They are elegantly expressed as follows:—"1. That the plan should be generally adopted for all gun-boats of taking away the mastic from under the boilers, and placing them upon iron crutches. 2. That in all new steam men-of-war, and in those whose boilers may require renewing, where there is sufficient space, mastic should not be used at all, but the boilers placed either upon iron crutches, sleepers, or the bearings should be rested upon putty, so that the bottoms of the boilers shall be completely accessible. 3. In cases where, from the build of the vessel, it is impossible to dispense with mastic, and where the boilers have to be placed by contractors, care should be taken that a well-qualified Government officer attends to see the work properly done."

In reply to these the Surveyor says, the evidence of the persons whose opinions were asked on this subject is by no means unanimous. To carry out the proposed arrangement the boilers must be placed higher in the ship, and it is with difficulty, even by reducing the steam space below what is desirable, and otherwise contracting their dimensions, that boilers can be kept sufficiently below the surface of the water to be reasonably protected from destruction by shot. Every effort has been made to keep them as low as possible, and except in special cases, the evils arising from raising them would most certainly outweigh the contemplated advantage; indeed, in a vast number of cases, the plan is altogether inapplicable. It is strange that any committee whatever could have forgotten this. The committee next consider that several changes might be advantageously adopted in the manner of proceeding with a steam-vessel arriving at a home port with defects, both as regards treatment before repairs are commenced, and also in the manner in which they are carried out. After proper surveys and reports upon the defective engines have been made by the authorities, it should be determined, they say, whether they are to be repaired by the steam-reserve or by the factory; if by the steam-reserve, the captain and inspector of machinery in that department will have to take the requisite measures, and on them should rest the whole responsibility. If heavy castings are required, application must be made to the chief engineer of the dockyard, who will have to give the necessary directions. The committee are of opinion that by following out this plan the dockyards will be relieved from a considerable amount of labour, which can be beneficially applied in a different direction, and the expenditure in making repairs will be reduced. "As the repairs will be effected by those artificers who have been to sea and witnessed the working of steam-engines under various circumstances, it therefore may be expected that the work will be better done by them than by workmen who are not conversant with engines at sea." To meet the necessities of the additional work thus entrusted to the artificers of the ship and the steam-reserve, a floating workshop (like those at Sheerness and Devonport) ought to be provided at Portsmouth; the one at Devonport ought to be enlarged and improved; "and all these floating factories, if at all deficient in their internal arrangements, ought to be at once furnished, and properly fitted up with simple but useful tools." (Let the reader conceive of an Admiralty report with such wise observations as this last abounding in it!) When extensive repairs are being carried out the chief engineer of the ship should be in constant communication with the chief engineer of the factory, to point out those defects of the engines that are most prominent, and most necessary to be remedied. "The committee consider the above a matter of importance, and are convinced that if carried out in a proper spirit much good will result from this intercourse." Another "matter of importance" is that "the engineer who conducts the construction and repairs of marine engines in a factory should have had experience of the working of engines at sea." To this the Surveyor replies that at present out of the chief engineers of the dockyards and their principal assistants, amounting altogether to eight, there are no less than four who have been naval engineers. "It is apprehended," by him, that "the Board would never think of laying down any fixed rule, such as that suggested by the committee, which would limit them in their selection of individuals to fill these important posts."

The purchase and cost of steam-machinery is the next topic touched by the committee. In compliance with the directions given to the committee by the Admiralty, they "have given special attention to the manner in which purchases should be entered into, and also into the cost, marking at the same time where there has been in these transactions any want of economy that ought in future to be avoided." As a preliminary remark, the committee observe that the improvements lately made in steam-engines and boilers have a tendency to increase their cost. The tubular boiler with brass tubes costs more than the flue boiler, and the direct-action engines for propelling the screw are not only more expensive to purchase than those used for the paddle-wheel, but require a greater expenditure of tallow and oil for facilitating the motion; it would be easy to state many more changes connected with the structure of engines which have at all events required, for the present, extra expense. It appears to the committee that this circumstance, by causing larger sums to be expended necessarily under special heads, may have a tendency, if not strictly guarded against, to check that proper economy which is so necessary, and so difficult to retain in all large concerns. "Impressed with this idea, the committee submit to their lordships' consideration a few cases of large sums spent without adequate results upon steam machinery, which they hope may act as beacons to guide future expenditure." We shall not follow the committee into the details of their charges under this head. They are neither very numerous nor very strong; and they are all sufficiently replied to by the Surveyor, who concludes his observations on this head in the following sentences, which we quote in justice to the Department:—

When a great and beneficial change has been effected, such as the change from the paddle to the screw, whereby steam has been rendered applicable to ships of war of all classes, it is generally easy to look back at the several efforts that were made to accomplish the object, and to point at some of them as having contributed to the result less than others. No doubt, with our present knowledge and experience, and as it were seeing at a glance the whole course pursued, and its successful termination, this may be done without much risk of error. But it should not be forgotten, as it sometimes is in this particular case, that many competent judges thought the screw system of propulsion could never be successfully carried out, and that the invention had to struggle against adverse opinion, and no small opposition; such opponents, however, would now probably admit that the comparative failures in effecting this great change were fewer than they themselves expected, and fewer than have generally attended the introduction of equally important changes from one mechanical system to another.

The committee next direct attention to the method adopted by the Admiralty when making their contracts for the purchase of engines and boilers. Years ago, when engines were wanted for the navy, it was the practice to apply to almost all the known respectable firms, giving very often a preference to those makers who could place the greatest amount of power in the smallest space. No doubt that was apparently the most economical manner of pro-

Digitized by Google

ceeding, but it introduced many bad engines into the service. At the commencement of the Russian war the Government saw that it was necessary for the rapid supply of machinery to confide their orders to a few first-rate makers, amongst whom Penn and Son and Maudslay and Field were amongst the principal, and they did the country ample justice, considering how little time was afforded to complete the orders entrusted to them. These eminent firms were forced, however, the committee allege, during that press of orders so unexpectedly coming upon them, to apply to other engineers for some of the items in their contracts. Thus several makers who had formerly supplied the Government with engines gradually were thrown out of the list, and at present the contracts are almost limited to Penn, Maudslay and Field, and Miller and Ravenhill. A good deal of trouble is thus saved, and the committee say they have reason to believe that the best steam-machinery that this country can produce has been lately received. Further, from every inquiry that the committee have made, after visiting most of the principal manufactories of steam-engines, as well as receiving important information from most of the great steam-companies, they have no reason to believe that the Government have generally paid a higher price for their engines and boilers than private individuals have done. These statements are succeeded by the following curious remarks :—

The committee are of opinion, that although this plan of purchasing engines has been adopted by several large steam companies, still they think that the Government could advantageously throw their contracts more open. A special advantage of this mode of conducting the contracts has offered itself to the committee. The Government would certainly gain a better and more extended knowledge of the real state of the engine market. It even appears doubtful to the committee whether the steam authorities at the Admiralty have been made aware that the factories for constructing marine engines at Glasgow, and its immediate vicinity, are of such a complete and extensive a nature, that from them, perhaps, could be furnished marine engines for the whole of Europe. The greater number of these Glasgow engineers have never had an opportunity afforded them of constructing steam machinery for our men-of-war, and of course may not be so well acquainted with all the requisites and limits that are necessary for that species of engine. In this case, therefore, and indeed in most cases, the steam department of the Admiralty ought to furnish their own plan of engine; but, at the same time, in order that they may be kept cognizant of all improvements, the parties tendering should be requested to send in plans and tenders for such engines as may appear to them superior. In time of war, and when sudden pressure of demand came upon the Government for work upon which they could depend, they would then have acquired such knowledge as would enable them to apply at once to new resources, by which the country could be kept supplied in almost the shortest possible time with engines for every variety of vessel.

The committee next refer to an extract from a letter from Sir Baldwin Walker, Surveyor of the Navy, on which they make a few very hostile remarks :—

That letter states, they say, that the difference between the steam machinery required for men-of-war and that which is suitable for mercantile steam-vessels is so great, that for large steam-engines entire trust ought to be given only to those makers who have been in the habit of supplying engines to the navy. Certainly this remark implies an argument, whether intended or not, for employing more engineering firms than is done at present. In that letter it also stated, "if the Admiralty did not employ, to a considerable extent, the very best makers in this country, foreign countries, and particularly those which may at a future time be our most powerful enemies, would be more benefited by the purchase of English engines than they have been within this last few years." Now, whilst the committee fully and entirely concur in the opinion that only the best makers for large engines ought to be employed by the Admiralty, they must protest against the reason assigned for that measure as wholly fallacious. It is in vain to expect, in these days of free and open commercial relations, that any purchase of steam-engines by the Admiralty from a few eminent firms will for any length of time prevent foreign countries from supplying themselves with the best steam machinery that this country can produce. Even if any such effect were the result to a partial degree, the only consequence would be to force foreign countries to manufacture their own engines. In the course of their inquiries, the committee have been led to the opinion that some improvements might be made in the mode of taking the contracts for providing steam-engines for the navy. The specifications do not appear to be sufficiently comprehensive; one deficiency has been referred to by Mr. Murray, chief engineer of Portsmouth Dockyard, who stated as follows:—"I have always been of opinion that the indicated horse power up to which the engines are to work, with a given supply of coal of average quality, should be inserted in the contracts."

The committee entirely agree in this opinion, and see no reason why a specific clause should not be inserted, embracing that point in all future contracts for steam-engines. They also agree with Mr. Murray that it would be highly advantageous, whenever the authorities have approved generally of the drawings, and accepted the tender sent in for any pair of engines, that a power should be reserved of arranging with the contractor for any minor improvements that might be considered advantageous after the general approval has been given. It appears that hitherto two reasons have prevented the steam professional advisers of the Admiralty from interfering with the contractors. The first is a fear of laying themselves open to a charge of favouritism, by preferring some particular party. The second reason is, that in the event of the engines failing, it has been considered advisable that the whole of the responsibility should be thrown upon the contractors. The committee cannot see any force in either of these reasons; and, indeed, they consider the second one to be entirely fallacious. They concur in the opinion given by Mr. Murray, that the responsibility of the contractors practically ceases as soon as the most important parts of the engine are passed, and the greater proportion of the instalments made. The professional advisers of the Admiralty are, practically speaking, the parties upon whom the responsibility rests. It is necessary that they should be well acquainted with every new improvement that has been found applicable to the marine steam-engine. And, further, they should not only take care that these improvements are adopted in all new machinery, but by careful supervision, as far as supervision can avail, should prevent either bad workmanship, the use of hot-blast iron, or any other inferior material.

To all this the Surveyor makes a very full reply, which deserves careful attention, but which can scarcely be considered sufficient. At first sight, he says, any extra condition in a contract seems calculated to secure a better bargain for the buyer; but whether it actually does so, depends mainly upon the feelings, interests, and character of the person undertaking it. Experience shows that it is not easy to ensure the faithful fulfilment of the simplest contract when a contractor is unprincipled and endeavours to evade the conditions, or barely to fulfil them to their strict letter instead of their spirit. With such a man it is presumed the Government would not desire to have any dealings at all. But men of the opposite character not unfrequently undertake to do more than can be performed; as, for instance, to build a ship with a given draught of water to realise a certain speed under certain conditions, or to make her engines work up to a certain amount of power with a given expenditure of fuel. Such failures generally end in a sort of compromise. Now, under ordinary circumstances, this does not seem to be the most suitable kind of contract for the Government to make, and accordingly it is very seldom had recourse to. The general system adopted by the Admiralty for obtaining engines, is to specify beforehand the minimum area of fire-grate, and of absorbing surface of the boiler, on which the power mainly depends, and to approve of the size of cylinder, length of stroke, and other particulars of the engines before the tender is accepted. That eminent marine engineers would do their very utmost, regardless of cost, to realise the best results which can be obtained is notorious; but it is not so generally known that even some time after an engine has been set to work, if they discover an improvement which can be introduced, or an indication that any part has not worked or may not continue to work in a perfectly satisfactory manner, they earnestly solicit, as a favour, permission to alter or renew them at their own cost; and with one or two solitary and not recent exceptions, they have never hesitated to remedy at their own cost every defect, apparent or real, which has been pointed out to them. No doubt, their own interest would alone prompt them to do all this, but it is right the fact should be known.

Such being the case, it may be asked (says the Surveyor) is it probable that if the proposed condition were inserted in future contracts, that with a certain quantity of coal of "average" quality—a vague definition—a certain amount of power must be realised, it would have the effect of eliciting greater skill or judgment on the part of the manufacturers? But further, if this amount of power were fixed at a point difficult to attain—and without so fixing it the condition would be simply useless—might it not be an inducement to them, rather than risk a failure, to endeavour to effect the object without due regard to permanent excellence, or the satisfactory working of engines and boilers under the ordinary requirements of the service? If, however, this condition is intended by the committee to be a part of their proposed system of having engines made on a Government plan, and of designing and manufacturing the boilers in a Government establishment, thus reducing the manufacturers to mere operatives acting under the directions and supervision of Government officers, it is evident the committee cannot have considered the subject with any degree of attention. The two recommendations are obviously incompatible. It may perhaps be unnecessary to add, that no condition which is not clear and specific ought to be inserted in a contract, unless indeed some paramount object is to be gained. In the present instance, however, such does not appear to be the case, for the committee do not even state the object which they have in view, and it may well be doubted whether an important one could be found. Now, as was before observed, coal of "average" quality is a vague definition, but this is not all. It is well known that the actual power developed by an engine, which is seldom two days alike, depends upon many circumstances other than its own merits and those of the coal and boiler; such as the draught of water of the ship, state of the weather, direction of wind as affecting the ventilation of the stoke-hole and the draught of the boiler, skill and energy of stokers, duration of trial, quantity of water blown out of the boilers to prevent incrustation, degree of expansion used, &c.; and when it is borne in mind that with a boiler of given size and construction, every experienced person can predicate within very narrow limits what power it will realise if the steam be made proper use of. The difference between the power specified in the contract and that realised would never be very great; hence the aggregate influence of the circumstances before referred to would become the chief point in dispute, and it is more than probable differences of opinion on this and on the mode of conducting the trials would lead to a want of harmony and co-operation between contractors and Government officers, than which nothing more detrimental to those public interests with which they are connected could possibly happen; while on the other hand no benefit whatever could possibly be gained.

The committee recommend, further, that in all future specifications for new engines a clause be inserted, excluding entirely the use of hot-blast iron. From various inquiries which have been made, the committee are convinced that even the engineers of our Government factories are not sufficiently impressed with the vast difference which exists between the strength of hot and cold-blast iron. When at Sheerness the committee witnessed the following trials, to

Digitized by Google

test the difference of strength between a pig of iron made by hot blast, and a similar one made by the cold blast. The difference was at once apparent: they found that a single blow with a small sledge hammer broke the pig of iron made by the hot blast, and that repeated blows very soon broke it up into fragments. The pig of iron made by the cold blast, on the other hand, resisted entirely the stroke of the same hammer by which the other had been broken so easily, and further, that it stood un injured even repeated blows with a very large sledge hammer before it broke. The difference was apparent also in this, when the hot-blast iron was thrown upon the ground it broke immediately from the effects of the fall, whereas the cold-blast iron bore a similar treatment without the slightest injury. The committee having witnessed these trials, having inquired carefully into the subject, and having ascertained that, on an average, if sixty represents the cost of hot-blast iron, 120 represents the cost of cold-blast iron, which also may be taken as their relative mechanical value, strongly urge upon their lordships the necessity (seeing the temptation is so great) of taking the most stringent steps to prevent the introduction of any portion of hot-blast iron into the castings required for the Government engines. They further add, that they believe a large proportion of the breakdowns that take place on board steam-vessels proceed from the use of this very inferior metal. By way of rejoinder to this, the Surveyor says it is but just to those manufacturers who have been employed by the Admiralty to say that there is no reason whatever to suppose, nor indeed is such an imputation made against them, that they have used it injudiciously. "The principle of prohibiting the use of a material which, when used with judgment, is unquestionably productive of benefit, because it is cheap, and may be improperly used by unscrupulous persons, cannot be defended. The adoption of such a principle would be calculated to discourage improvements and check advancement in the manufacturing and mechanical arts; indeed, in the present day it would be as anomalous as it certainly would be contrary to sound policy."

The committee next recommend that engines alone should be purchased, and that boilers, screw-propellers, and it may be presumed everything connected with them, should be manufactured in the dockyards; this would amount to nearly one-half of that which is now supplied under contract. If this recommendation were ordered to be carried out, no doubt many of the difficulties and objections which at once present themselves, and which appear of a serious character, would not be found insuperable; but, as the Surveyor says, a proposition to increase to such an extent the system of costly manufactures in the dockyards could not be decided in the affirmative without grave consideration, and a more close investigation and a fuller inquiry than it appears to have undergone by the committee. He further says, the general question of manufacturing in public establishments what can always be obtained by contract is not new; it has been frequently discussed, but without gaining many supporters. A strong feeling seemed to prevail in the minds of the Select Committee of Navy and Army Estimates in 1848, that even at that time the system required rather to be checked than extended, and whether right or wrong, persons in high position and of great judgment are now found, occasionally, to express in Parliament and elsewhere the same opinion. The committee's suggestion to have in progress of manufacture at each of the factories an engine, with the special or principal object of absorbing labour when not required for repairs, is one which, if adopted, would, in the opinion of the Surveyor, have the good effect of sometimes obviating the necessity of discharging men. But their further suggestion, that the boilers and screws for all new engines should be made in Government factories, and, in addition, that a large number of engines should also be made in these establishments, does not meet with his approbation. They also suggest that the remaining engines should not be obtained as heretofore from the eminent engineers whose plans they have decided to be the best and the most suitable for ships of war, but that two or more of these plans should be selected, or others invented by Government officers, and that complete working drawings and specifications should then be prepared and placed in the hands of such manufacturers as may be willing to undertake work under these conditions. Engines may, it is assumed, be thus obtained at a reduced price, and of the same or superior excellence. "Now, the only inquiry the committee seem to have made as to the expediency, or even practicability of adopting such a system, was," says the Surveyor, "by asking certain manufacturers if they would be willing to construct engines on a Government plan, not whether they would construct them on the plan of another manufacturer, and reduce themselves to mere operatives, having only to conform to detailed drawings, and to submit implicitly to the directions of Government officers: but it is worthy of remark that the two most eminent firms in this or any other country, Messrs. Maudslay and Messrs. Penn, were not asked even that question; their reply, if they had been, may be readily conjectured. Mr. Humphreys, whose engines, at least for small power, the committee consider the best adapted for the Royal Navy, was asked, and he said he would not. If therefore this engine is to be procured for the future, it must either be made by him as heretofore, or we must make drawings of it, and endeavour to induce manufacturers to adopt a course which it is hoped few people could reconcile to their views of right and wrong, unless they considered the moral responsibility rested with the Government. The patent right for Mr. Penn's engine it is understood will shortly expire, as in the case of Messrs. Humphreys, there would be no legal impediment to supplying manufacturers with drawings of Mr. Penn's engine, to enable them to make engines on his plan also. To expect, however, to obtain in this manner engines of the same excellence as those manufactured by the inventors themselves, at all events for some time to come, is altogether unreasonable. For every kind of engine there are particular adjustments and allowances required, and for certain parts a suitable selection and treatment of materials, a knowledge of which can be acquired only by long practice, and cannot be communicated by any drawings or instructions. It relates more especially to those practical details learned by experience in constructing a succession of engines on the same plan. Moreover, it would be difficult, if not impossible, to ensure the same excellence of workmanship in ordinary engineering establishments."

ALEXANDER VON HUMBOLDT.

THE great Humboldt is no more. Full of years and honour, he died in his native city of Berlin on Friday last. We should deem it a delight to write a worthy notice of one so illustrious, had we the leisure, and the faculty, and the culture essential to the task. But we have neither: it were mere charlatanry to pretend to it. Happily his fame needs no aid of ours. His memory is graven on the world for ever. The following few facts concerning him, from another source, may be repeated here. Alexander von Humboldt was born at Berlin on the 14th of September, 1769. He was an undergraduate at Göttingen, which university he left for Frankfort-on-the-Oder. Geography and geology where is chief studies. His intelligence and zeal were not overlooked by the Government. In 1795 he was sent by the Prussian Government to study the nature of the volcanic eruptions of Vesuvius. Humboldt's mind took a wider range. He aspired to investigate regions unknown. Africa was his object. He went to Marseilles and joined Bonpland, who was on the point of starting on a similar mission, with the intention of accompanying him. This plan failed, but through the interest of Baron Forell, the Saxon Ambassador, Humboldt obtained permission and authority to make a scientific tour of Spanish America. During 18 months Humboldt examined geologically and geographically every part of Venezuela, the Orinoco, and the Rio Negro. He afterwards visited Bogota, the Cordilleras, and Quito. At this latter place Humboldt, at great personal risk, investigated the volcanic mountains. He spent some time at Lima. In August, 1804, Humboldt landed at Havre, rich in experience, and with an invaluable collection of specimens of geological and botanical interest. Humboldt fixed his residence at Paris, taking an occasional trip to London; but Prussia could not spare so valuable a man, and the King requested Humboldt to return. The King made him a Privy Councillor, and offered him various diplomatic missions. But mountains, not men, were Humboldt's object. He wished to explore the Andes and the Himalayas, to make a comparison of their respective dimensions. This plan failed. He, however, succeeded in another. He started for Siberia, and then visited the chief cities of Russia. There is not one branch of science to which Humboldt has not contributed something—nay, much. The powers of his mind seemed to increase as they produced. The friend of Kings, he was a Liberal. He took a large view of the world in a political sense while investigating with the utmost minuteness the conformation of some unknown substance. Doubtless we shall shortly receive from some German pen a worthier notice of one of Germany's greatest celebrities.

The following telegram from Berlin on Tuesday last tells enough of what remains:—"The solemn funeral procession of Alexander von Humboldt is now on its way to the Cathedral. All that represents science, art, and intelligence in Berlin joins in the procession. Three Chamberlains in gold costume, bearing the orders of the illustrious deceased, precede the funeral car, which is drawn by six horses from the Royal stables. Upon the car is a simple uncovered coffin of oak adorned with flowers and laurel. On either side of the car are students, bearing green palm branches. A line of carriages of immense length closes the procession. The Prince Regent and all the Princes and Princesses are assembled in the Cathedral, awaiting the arrival of the great philosopher's mortal remains. A mournful aspect overspreads the whole town."

DR. LARDNER.

ON the 4th inst. at Naples (not Paris, as has been said), died Dr. Dionysius Lardner, the best popular scientific writer in the English language. His labours were as useful to the nation as they were honourable to himself. He was born at Dublin in 1793, and after some time spent in the office of his father, who was a solicitor, he was entered at Trinity College, Cambridge, and devoted himself to scientific studies. He soon showed that he had now chosen the right path in life, and rapidly gained an extraordinary number of prizes in pure mathematics, as well as in natural philosophy, astronomy, and other branches of study. In 1817 he obtained a B.A. degree, and for ten years remained at the University, publishing at first various treatises on mathematics, including the differential and integral calculus, and subsequently on the steam-engine. For this he obtained a gold medal from the Royal Dublin Society; and his reputation being now in a great measure esta-

Digitized by Google

blished, he began to contribute to the *Edinburgh Encyclopædia* and the *Encyclopædia Metropolitana*, writing elaborate articles on pure mathematics, as well as on the applied sciences. In 1827, on the establishment of the London University, Dr. Lardner accepted the chair of Natural Philosophy and Astronomy, and removing to London, he set on foot a scheme for a *Cabinet Encyclopædia*, which he gradually perfected, obtaining the co-operation of many eminent men. Sir John Herschell wrote a paper for this book which attained considerable celebrity, "The Preliminary Discourse upon Natural Philosophy," but most of the scientific articles are due to Dr. Lardner himself. In 1840 Dr. Lardner went to the United States, and delivered with much success a series of lectures, which have since been published. After devoting much time to "Railway Economy," and writing a good deal on this and other subjects, Dr. Lardner started his last important work, the *Museum of Science and Art*, which contains many of the best popular treatises on science which have ever been written. He was for manyyears a contributor, to a greater or less extent, to the MECHANICS' MAGAZINE. His last communication was upon the vexed question of the moons' rotation, and appeared a year or two since. Dr. Lardner has left one son, a commissary-general of the British army, and two daughters, the issue of two marriages.

Proceedings of Societies.

INSTITUTION OF CIVIL ENGINEERS.

April 19.—Joseph Locke, Esq., M.P., President, in the chair. The Paper read was "Description of the Entrance, Entrance Lock, and Jetty Walls, with the Wrough-iron Gates and Caisson, &c., of the Victoria (London) Docks," by Mr. W. J. Kingsbury, Assoc. Inst. C.E. This Paper had chiefly for its object, to bring forward an account of some special works, which from their magnitude and peculiarity presented novelty and interest; it was, therefore, rather a contribution to the history of the Victoria Docks, than an attempt to convey a complete idea of that undertaking. The Victoria (London) Docks were briefly described as being situnted in that part of the Plaistow Marshes, Essex, which, projecting forward towards the south-east was bounded on three sides by the River Thames, which there formed a loop, or bend, extending from Bugsby's Reach, just below Blackwall, to Galleon's Reech, below Woolwich. The entire area comprised within the dock was shown to be about 200 acres, of which one-half, or 100 acres, was water space. This consisted of the entrance, with its lock, the tidal chamber of 18 acres, and the main dock of 74 acres. In general terms, the basin and dock together were 4,050 feet in length, and 1,050 feet in width at the level of high-water mark. In addition to the quay room afforded by the sides of the basin and dock, four jetties, each 581 feet long, and 140 feet wide, were projected from the north side into the dock; these jetties, with the sides of the dock and of the basin, provided a length of three miles of quay space. The descriptive portion of the paper was too technical to be usefully described without engravings.

May 3.—P. Bidder, Esq., Vice-President, in the chair. The paper read was "On the Tyne Docks at South Shields, and on the Mode adopted for shipping Coals," by Mr. T. E. Harrison, M. Inst. C.E. These docks had been constructed on the banks of the River Tyne, at the upper end of South Shields, on a large area called Jarrow Slake, which was covered with water at spring tides, to a depth of from 5 feet to 8 feet. The area so covered amounted to about 350 acres, and of this quantity 179 acres were now inclosed. The area of water in the dock, as executed, was 50 acres, the depth of water being 24 feet 6 inches at an average spring tide. The entrance basin was 9½ acres in extent, with a depth of water of 25 feet, for a width of 200 feet in the centre of the channel, gradually shoaling to the sides. One entrance had a width of 80 feet, and there was a lock of 300 feet in length and 100 feet in width, with gates 60 feet in width; the cills in each case were laid 24 feet 6 inches below high water of average spring tides—such spring tides having a lift of 14 feet 6 inches. The total quantity of excavation in the docks was 1,783,452 cubic yards, and in forming the standage ground 281,305 cubic yards. The total quantity of masonry of all descriptions was 2,000,000 cubic feet. The cost, up to the date of the opening for public traffic, was £140,476. This sum included all the standage and railway approaches, the shipping jetties, the purchase of land, and all the dockworks, but it excluded Parliamentary and other charges, not engineering. The works were under the immediate superintendence of Mr. Robert Hodgson, as Resident Engineer; and the contract for their execution was let to Mr. James Gow. A brief account was then given of the different methods of shipping coals, used at the Northern coal ports, during the last forty-seven years. The system of "keels" was first described; and it was stated that it still existed, to a limited extent, both on the River Wear and on the River Tyne, in the case of those collieries not having direct railway communication to a place of shipment. Where the vessels could reach the shipping places, as at the Wall's End Colliery, the mode of shipment was by spouts, in general principle the same as those adopted at the Tyne Docks; but without, for a long time, any arrangement for allowing for the difference in the level of the tide and in the size of the vessel. The first innovation on the "spout" system took place in 1812, when a coal-drop was erected at Pelaw Main Spout, on the River Tyne, by Mr. B. Thompson, further improved by him in 1813, and since generally followed, with various modifications. The principle of all these drops was, that the loaded waggon, in its descent, raised a counterbalance weight; and when the coals were let out of the waggon, the counterbalance weight brought the waggon back to its previous position. The system of tubs, fitted into "keels," in order to avoid the breakage of the coal, was then alluded to, and the machinery by which they were transferred to the vessel was briefly described. It was stated, that after mature deliberation, and careful examination of all the different plans, it was decided to adopt, in the Tyne Docks, the system of shipping by spouts. The angle of inclination of the spouts was 50°, that having been found by experiment to be the angle at which coals would slide on smooth iron plates, without rolling. In order to allow for the varying level of the ship's deck, which it was shown might amount, under certain circumstances, to 20 feet, arrangements were made to deliver the coals at four different levels. The coals were directed into any one of four divisions, by the opening or shutting of trap-doors, turning on hinges, and well balanced, so as to be easily moved. The spout was also raised, or lowered, in guides, and was operated by winches, the men standing on the level at which they worked when shipping coals. Traps were also provided for regulating the descent of the coals into the ship. In some cases, the spouts were made to slide in a frame turning on a pivot, the object being to give a greater range into the ship's hold, particularly with screw colliers, and thus avoid the necessity of moving the ship. In practice, the plan was to keep the spout nearly full, merely letting the coals slide sufficiently down to allow of the next waggon being teamed; so that, although in the first filling of the spout, or on altering the level of the spout, the coal had a few feet to fall, yet this only applied to a small quantity of coal. Afterwards the whole mass slowly descended, and no further breakage took place. Two jetties, on which there were twenty shipping places, were already at work. The shipping places were 100 feet apart from centre to centre, and were so arranged, that the vessels overlapped each other. Arrangements were made, so that the number of shipping places could be increased to fifty, as the trade required. In laying out the ground, the saving of manual labour had been a primary consideration, and gravity had been called into operation to the utmost possible extent. In order to ship the quantity of coals now transferred to, and being shipped in the Tyne Docks, there were employed last year at South Shields thirty-four horses and four pilot engines, and the work was carried on throughout the whole twenty-four hours. Under the present arrangement not a single horse was employed, and only two pilot engines, and the work was done generally in fifteen hours. At present there was rather a deficiency of standage for light waggons, but this was in course of remedy, and when completed no pilot engine would be necessary. The cost of labour for carrying the coal along the jetty, a distance of 1,050 yards, for the shipment, and for returning the empty waggons to the point where the engine took them up, was about seven-sixteenths of a penny per ton.

INSTITUTION OF MECHANICAL ENGINEERS.

May 4.—Henry Maudslay, Esq., Vice-President, in the chair. The Secretary (Mr. W. P. Marshall) read the minutes of the previous meeting, and a large number of new members were elected.

The first paper read was a "Description of the Pumping Engine at the Newcastle Water Works," by Mr. Robert Morrison, of Newcastle-upon-Tyne. This is a horizontal high-pressure expansive and non-condensing engine, working direct a double-acting pump placed opposite the steam cylinder, and controlled by a crank and fly-wheel. The water is drawn from a pure water basin, supplied by a filter bed, and is forced by the pump into a high reservoir for supplying the town by gravitation. The pump valves are rectangular flap valves of india-rubber, the delivery valves being placed immediately over the suction valves at each end of the pump; and a small air vessel is fixed over each of the delivery valves for the purpose of slightly easing their action, in addition to the large air vessel upon the main. The steam cylinder has an expansion slide, working on the back of the ordinary slide valve.

The next paper was "On the construction of Hot Blast Ovens for Iron Furnaces," by Mr. Henry Marten, of Wolverhampton; commencing with the origination and early development of the idea of hot blast by Mr. Neilson, of Glasgow, thirty years ago, and giving a description of the principal modifications and improvements that have been successively effected in the construction of hot-blast ovens. To remedy the defects still experienced, after many modifications, from expansion of the pipes the round form of oven was then contrived, having the fire-grate in the centre and surrounded by a circular main pipe, divided by a diaphragm all round into an outer and inner portion, on the top of which were placed a number of upright heating pipes, each consisting of two pipes cast in one piece, and communicating with each other at the top, one leg of the pipe opening into the outer division of the main, and the other into the inner; the two sockets of each pipe being close together and cast all in one piece were thus freed from the injurious effects of expansion experienced in the previous arched pipes. The blast passed up one half and down the other half of each pipe; and the top of the oven was built in a dome shape, so as to reverberate the heat from the fire upon the pipes. These round ovens have since been elongated into an oval form, to contain a greater number of heating pipes; and a central core of fire-brick has been added, filling up the vacant space in the centre of the oven, bringing the heat into closer contact with the pipes arranged round the sides of the oven, and acting also as a regulator of the temperature of the blast, by absorbing any excess of heat from irregularity of firing, and giving it out again an any diminution of temperature. Hot-blast ovens on this construction, with some further improvements in the arrangements for cleaning out without stopping, have now been in constant work for some time at the writer's works, and have proved thoroughly satisfactory, being quite free from any trouble, either from expansion or burning of the pipes, or from leakage at the joints; the blast is maintained uniformly at a temperature of about 800° Fahrenheit, producing an important increase in the yield of the iron furnace.

The last paper was "On Jenson's Marine Engine Governor," by Mr. Henry Maudslay, of London; the object of which is to prevent the engine from running off at an excessive speed, when the resistance of the water to the screw propeller or paddle wheel is suddenly removed by the pitching or rolling motion of the vessel in stormy weather. The governor consists of a piston working in a cylinder, the bottom of which communicates with an opening through the side of the vessel, as near as possible to the propeller or paddle wheel; the pressure of water in the bottom of the cylinder thus corresponds exactly with the depth of immersion of the propeller, and tends to raise the piston, which is loaded on the top by an adjustable spring, and connected by bell-crank levers and links with a throttle valve in the steam pipe of the engine. When the motion of the vessel causes the propeller to be less deeply immersed, the pressure of water in the cylinder is diminished, and the piston is forced down by the spring above, closing the throttle valve to the required extent, and preventing the speed of the engine from increasing; and, on the other hand, when the propeller is more deeply immersed, the pressure in the cylinder is increased, and raises the piston, opening the throttle valve and admitting more steam to the engine, so as to maintain the required speed; the object being to control the speed of the engine before it has time to change sensibly, instead of waiting for a change of speed in the engine to bring the governor into action, as in the case of the ordinary engine governor.

ASSOCIATION OF FOREMEN ENGINEERS.

May 7.—At the monthly meeting of the Association of Foremen Engineers, held at the Bay Tree Assembly Rooms, City, on the 7th inst., a paper was read by Mr. John Briggs on the "Concussion of Water." Mr. Joseph Newton presided on the occa-

Digitized by Google

sion, and a full attendence of members encouraged the reader in his task. The difficulties which beset the path of the hydrostatic engineer, were in the first instance referred to, and the more particularly, as regarded the working of forcing and lifting pumps. The methods of overcoming those difficulties, by attaching to the suction and delivery pipes air vessels, and attending to the proportionate sizes of the pipes themselves, as compared with those of the working barrels, were next described; Mr. Briggs' own practical experience in such matters making his explanations the more clear and valuable. It is not improbable that at a further period, and when our columns are less crowded than at present, we may give more extendedly the substance of this important contribution to the transactions of the Society. The discussion which followed the reading of the paper, and in which Messrs. Keyte, Stabler, M. Jones, Ferguson and the Chairman took part, was protracted till nearly 11 o'clock, when its adjournment till the meeting on the first Saturday was put and carried. The meeting soon afterwards came to an end.

ROYAL AGRICULTURAL OF ENGLAND.

May 4.—Monthly Council. The Duke of Marlborough, President, in the chair. Mr. R. Barker, chairman of Finance Committee, presented the report, by which it appeared that the current cash balance in hand was £1,583 1s. 8d. The report of the Inspection Committee having been read and deputations received from Canterbury, Croydon, Guildford, and Reigate, the Council decided that the Country Meeting in 1860 should be held at Canterbury, on condition that the Mayor of that city entered into the usual agreement with the Secretary of the Society by the next Monthly Council on the 1st of June. Mr. Wren Hoskyns, chairman of Chemical Committee, presented the report recommending that the wording of the rule regulating the members' privilege of analysis be altered so as to meet the intention of the Council, viz., so as to exclude all but analyses "required for the *bonâ fide* personal use of farmers." The following subjects of investigation by the Society's Consulting Chemist were recommended:—1. The changes that take place in liquid manure in passing through different soils. 2. Experiments on top-dressings for Wheat and Barley. 3. The continuation of his experiments on the nature and physiology of cultivated turnips. 4. The different modes of applying manure in autumn and in spring. Mr. E. Pope was elected one of the Stewards of Implements, in the place of Lieut.-Colonel Towneley. Mr. Fisher Hobbs was elected Steward of Live Stock. On the motion of Mr. Brandreth Gibbs, a communication from the Secretary of the Crystal Palace, inquiring relative to the Society's proposed Metropolitan Meeting in the year 1861, was referred to the "Metropolitan Sites Committee."

MEETINGS FOR THE ENSUING WEEK.

MON.—*Royal Geographical Soc.*, Anniversary Meeting, at 1 p.m.

TUES.—*Royal Inst.*, "General facts and leading principles of Geological Science," by John Morris, F.G.S., at 3 p.m.

Statistical Society—1. Mr. Welton—"On the Occupations of the People of England and Wales." Part II. 2. Mr. Acton—"On Illegitimate Births in Marylebone, St. Pancras, and St. George's, Southwark," at 8 p.m.

Inst. Civil Engineers, "Short account of the Wrought-iron Girder Bridge over the Spey, on the Aberdeen and Inverness Railway," by Mr. W. Fairbairn, M. Inst., C.E. "Description of the Government Water Works, Trafalgar Square," by Mr. C. E. Amos, M. Inst., C.E., at 8 p.m.

WED.—*Society of Arts*, "On the relative values of Coal and Coke in Locomotive Engines," by Mr. Benjamin Fothergill, at 8 p.m.

Geological Society—I. "On the Nomenclature of the old Red Fishes," by Sir P. Egerton, M.P., F.G.S. II. "On the Yellow Sandstone of Dura Den, and some of the old Red Fishes," by the Rev. J. Anderson, F.G.S., at 8 p.m.

Royal Agric. Society, Weekly Council, at 12 a.m.

THUR.—*Society of Antiquaries*, at 8 p.m.

Royal Society, at 8 p.m.

Chemical, at 8 p.m.

Royal Inst., "On the seven periods of Art," by A. H. Layard, Esq., at 3 p.m.

Linnæan, at 8 p.m.

FRID.—*Royal Inst.*, "On the colours of shooting Stars and Meteors," by John Hall Gladstone, Esq., F.R.S., at 8 p.m.

Royal Geographical Society, Audit of Accounts, at 11 a.m.

SAT.—*Royal Inst.*, "On Modern Italian Literature," by J. P. Lacaita, Esq., at 3 p.m.

Literature.

The Life of James Watt, with Selections from his Correspondence. By JAMES PATRICK MUIRHEAD, M.A., &c., with Portraits and Woodcuts. Second Edition. London: John Murray, Albemarle-street. 1859.

(SECOND NOTICE.)

LITTLE Scotland has played a grand part in world-history. Her earliest ages produced the finest types of physical courage and personal independence. Out of these, as out of a brawny frame, she developed, at last, intelligence and soul. She gave the world that sublimest of all spectacles, a whole nation raised to a glow and white heat of insight and pious fervour, when in every village and town her people signed their sacred covenant to defend the truth and one another. And she it was that last century gave to the world an instrument that, more than any other material thing, has metamorphosed the stage of human activities. In Great Britain alone, the steam-engine at this hour is achieving what would demand the manual labour of four hundred millions of men, or more than double the number of males supposed to inhabit the globe! Altogether, the history of the steam-engine is a romance, and makes us of these prosy years conscious that miracle and poetry are not dead.

To call James Watt the creator of the steam-engine seems only his fair portion of renown. Before he directed his mind to it, the sole use to which it was applied was to pump water from mines; but he, by his separate condenser, so transformed it that he made its uses universal.

Watt was another fine instance of the law that the hand cannot say to the brain, "I have no need of thee." The rude, hard, loud, practical, go-a-head world has to wait on and repair to the thinker as the well-head of all its life. Watt was a man of immensely preponderating brain. As a boy he had poor physical health; had little taste for most of boys' sports; but read books, especially of an imaginative cast, greedily, and was already of a meditative bent. And he grew up to be a sensitive, contemplative, imaginative person; shy and modest to an excess, and almost morbidly averse to practical life. "I find myself out of my sphere," he writes, "when I have anything to do with mankind; it is enough for an engineer to force nature, and to bear the vexation of her getting the better of him. I declare I had rather face a loaded cannon than settle an account or make a bargain."

The story of Watt's invention is the story of a pure birth of genius. And how alike is the working of genius, whatever its bent be, whether toward physical nature, or metaphysics and poetry; genius is so different from talent, reflection, and labour, though always allied and co-operating with these. How happy are our common names for her workings! The word "invention" means an accidental coming upon, alighting on a thing. "Discovery" means the lifting-up the lid that concealed one of nature's secrets. The blest Eureka comes by long waiting and looking. The search exacts great labour, and the discovery is the parent of yet more labour, but no labour ever procured the prize. How long James Watt brooded over his problem! "But I continued," he says, "to grope in the dark, misled by many an *ignis fatuus*. At length, as I was walking one Sunday afternoon, in the spring of 1765, the solution of the problem suddenly flashed upon my mind." Long years of labour and difficulty and sorrow it costs him to realise his idea; but necessity is laid upon him, and woe be to him if he obey not his vision. Once he writes:—"I have now brought the engine near a conclusion, yet I am not in idea nearer that rest I wish for than I was four years ago. However, I am resolved to do all I can to carry on this business; and, if it does not thrive with me, I will lay aside the burden I cannot carry. Of all things in life there is nothing more foolish than inventing." And long after, when somebody was expressing his admiration at his great achievements, he replied:—"The public only look at my success, and not on the intermediate failures and uncouth constructions which have served as steps to climb to the top of the ladder."

Take the following as a glimpse of his sly humour: he is describing, in a letter to a friend, the impression produced by one of his earliest engines, when he says—"The velocity, violence, magnitude, and horrible noise of the engine, gives unusual satisfaction to all beholders, believers or not. I have once or twice trimmed the engine to end its strokes gently and make less noise; but Mr. ——— cannot sleep unless it seems quite furious, so I have left it to the engineman. And, by-the-by, the noise seems to convey great ideas of its power to the ignorant, who seem to be no more taken with modest merit in an engine than in a man."

To those who only knew Watt as an *engineer*, how touching are these words of the *man!* Writing about his wife's death, he says—"I know that grief has its period; but I have much to suffer first." And again, writing on "the loss of friends," he says—"Like other evils, it must be endured with patience. The most powerful remedy is to apply to business, or amusements, which call the mind from its sorrows, and prevents it from preying on itself. In the fulness of our grief we are apt to think that allowing ourselves to pursue objects which may turn our minds from the object it is but too much occupied with, is like a kind of insult or want of affection for the deceased, but we do not then argue fairly: our duty to the departed has come to a period, but our duty to our living family, to ourselves, and to the world, still subsists; and the sooner we can bring ourselves to attend to it the more meritorious." And as strongly as he attached himself were others attached to him. Dr. Black (his old friend) sheds tears of delight over his success: "It's very foolish, but I can't help it when I hear of anything good to Jamie Watt." Watt lived to be nearly 83 years old, though of frail health from his childhood—another proof that the intellect is the life of the body, and not the consumer of it.

Directions for Laying Off Ships on the Mould-Loft Floor. With some Instructions for Drawing Ships in Perspective. By JOHN FINCHAM. *Third Edition.* London: Published by Whittaker and Co., Ave Maria Lane. 1859.

THIS work—which, in its former editions, is well known as the standard work on Laying Off throughout H.M.'s Dockyards—was first written for the use of the pupils of the late schools of Naval Architecture, and of shipwrights in the various mould-lofts. The applications made for copies after the second edition was out of print were so numerous as to induce the author to print a third. We are not quite sure, as we write, that this third edition has not been out some time; indeed, we have reason to believe that the new issue is, properly speaking, no more than a re-appearance of the third edition; but we cannot at the moment lay our hand upon our former copies, to see if it be so; and the matter is really of no importance. The author's age and health have unfortunately been such for some time as to preclude him from adding anything to the volume on its present appearance. But in its old form it will prove of the greatest value to young shipbuilders, at least until some more complete and comprehensive work, for which there is certainly room, makes its appearance. There must be many young men, we should think, to whom Mr. Fincham's book would be invaluable.

Beeton's Dictionary of Universal Information. By S. O. BEETON and JOHN SHEREER. Parts 1—6. London: S. O. Beeton, 18 Bouverie-street, E.C.

THIS is another of those marvels of cheap and excellent literature which we have lately had occasion to notice. We are told that this work, which is to be completed in 24 parts, at 3d. each, is to contain a complete gazeteer of geography—a perfect cyclopædia of history—a comprehensive compendium of biography—an interesting epitome of mythology—an inestimable treasury of Bible

Digitized by Google

knowledge—a reliable chronological record—and the correct pronunciation of every proper name: and we really believe the promise will be very fairly fulfilled. In the six parts before us we have four very good maps, a plate of coins, a tabular calendar for 150 years, numerous good woodcuts, and 192 pages of well-written and well-printed matter. In order to test the value of the latter we have turned to several names not very well known until recently. The first we looked for was "Bangkok," the name of the capital of Siam, and under that name we found a very excellent summary of the characteristics of that little-known city. Other words were turned to with like result. It may also be mentioned that prizes, gold-watches, works of art, &c., are to be distributed among the subscribers to this work.

LIST OF NEW BOOKS.

Craig (W.) Influence of Electric Tension as the Cause of Epidemic, &c., Diseases, 10s.
Dickson's (J. R.) School Perspective, Illustrated, 5s.
Glenny's (G.) Manual of Practical Gardening, new ed., 5s.
James's Naval History of Great Britain, new edit., Vol. I., 5s.
Johnston's Map of the Seat of War in North Italy, 1s. 6d., sheet.
Jaeger's (B.) Life of North American Insects, with illustrations, crown 8vo, 8s. 6d., cloth.
Knight's (C.) English Cyclopædia: Arts and Sciences, Vol. I., 12s.
Lloyd's Map of the Seat of War, 2s., sheet.
Muirhead's (J. P.) Life of James Watt, 2nd edit., 16s.
Mitchell's (C. M.) Planetary and Stellar Worlds, new edit., 3s. 6d.
Monroe's (J.) Science and Art of Chess, 6s.
Nelson and Davies's New Atlas of the World, 12s.
Royal Blue-book, April, 1859, 5s.
Ruckard's (W.) Miner's Manual of Arithmetic and Surveying, &c., 10s. 6d.
Stanford's New Library Map of Europe, £3, in case.
Stanford's Map of Italy, 3s. 6d., sheet.
Stevens (R. W.) on the Stowage of Ships, and their Cargoes, Freights, &c., 2nd edit., 7s.
Webster's Royal Red-book, April, 1859, 12mo, 4s., cloth.
Wilson's (Rev. J. M.) Earth, Sea, and Sky, new edit., fcp. 8vo., 5s., cloth.

AN INVENTOR *v.* THE GOVERNMENT.

MR. GOSLING'S IMPROVEMENTS UPON THE ARMSTRONG GUN, &c.

TO THE EDITORS OF THE "MECHANICS' MAGAZINE."

GENTLEMEN,—In the *Journal of the Society of Arts*, Jan. 30, 1857, will be found the following announcement:—

"PIER AND HYDRAULIC CRANES, &c.—Of the miscellaneous services carried out during the war, one of the most important was the erection of a pier at the wharf of the Royal Arsenal, extending out into deep water, by means of which four of the largest class of vessels can be alongside during all conditions of the tide; and in connection with this pier is the application of hydraulic power to work the cranes. Hitherto, ships had to lie off in the river, and to be loaded or unloaded by means of barges, which were floated alongside, and to or from the wharf. By the new arrangement, four ships can draw up to the pier at one time, and by means of the hydraulic cranes the work of a week is reduced to ten hours, the limit to speed being the time required to stow away, or sling the articles within the hold of the vessel. During the six months ending the 30th November, 113 transports, representing a tonnage of 67,975 tons, were unloaded, which is exclusive of the ships that brought home the Land Transport Corps, the troops, horses, and their equipments. The whole expense of this service, including the steam-engine and hydraulic accumulator apparatus, and the cranes, amounting to nearly £33,500, *was cleared off in the saving of time of vessels alone during the first six weeks that it was in operation*, an important consideration, although secondary to the far higher advantage which it affords the War Department in the rapidity with which it can embark war materials and stores."

Such, gentlemen, is the testimony of Mr. John Anderson, chief engineer of the Royal Arsenal, in a paper which he read before the above Society in January, 1857, as before stated. And before entering upon an account of my improvements upon the Armstrong gun, I ask that justice may be administered in this matter; for the credit of the undertaking above set forth is due to me. If the Government will afford me an opportunity of confronting the select committee who examined and reported upon my plans to Lord Panmure, I shall be able to prove to them that the important advantages above enumerated were brought about entirely by my exertions. In the early part of the late war with Russia, I observed vessels lying in the river waiting to receive their cargoes, and found on inquiry that some of them had been detained at least 30 days, at a cost of nearly £100 per diem, in consequence of the very unbusinesslike system they had in conveying stores to these vessels, which was accomplished by barges being rowed from the wharf, whilst horses were conveyed by boats, and this could only be accomplished when tide and weather would permit. Unknown to the authorities, I at once furnished myself with the necessary data, by personal examination, and prepared my plans for a pier, in order that troops, horses, and stores might be transmitted to the decks of vessels as fast as they could be stowed. I then wrote to the Board of Ordnance, asking to be allowed to lay my plans before them. The Board immediately requested me to forward them. They were then sent to the Royal Arsenal for inspection and report of the select committee. The committee were convened, the merits of my plan were fairly discussed, a sum of money was named as the probable cost of carrying them out, and the report forwarded to the War Department. Not hearing anything from the Board for three weeks, I wrote a letter to Lord Panmure, pointing out the advantages which would be derived, should my plans be adopted, in reply to which I had the honour of receiving a letter, in which his lordship was pleased to say that *he had found on inquiry that my plans would be very useful, and that they should have his lordship's further attention.* Soon after the receipt of this letter, I found that several contractors had been applied to for tenders, and also that one had been accepted, and had commenced the works, whilst I was not so much as allowed to furnish a tender, although the committee knew that I was in a position at that time so to do. I found also that my plans had been altered, without the slightest improvement, but, on the contrary, involving a larger outlay, and requiring more time in transmitting stores. For I find from the foregoing quotation, that no less a sum than £33,500 has been expended, whereas £10,000 only was named as the probable cost of a structure such as I had proposed, which would have been far superior in appearance, and much more becoming this important manufactory and depôt of our country. Having thus stated the facts of the case, all I ask is a fair and impartial investigation. "Truth fears nothing but concealment." If the House of Commons will allow a special committee to be convened, so that the whole of the correspondence and plans may be laid before them, I have no doubt as regards the issue.

I have also another cause for complaint. It is now nearly four years ago since I first saw the advantages of a similar contrivance to that which I proposed for the Arsenal, if adopted at Her Majesty's Victualling Yard, Deptford. I saw that a vast amount of money must be unnecessarily expended annually for want of a better method of transmitting stores. I also found that a pier would not affect the navigation of the river any more than the pier now in use at the Commercial Docks adjoining. I therefore wrote to the Lords of the Admiralty upon the subject, and, at their lordships' request, forwarded my plans. Subsequently I received a letter from Mr. Osborne, announcing that their lordships were "not prepared to adopt the ingenious pier proposed by [you] me." But why should it not be adopted? Is the country so overstocked with cash that she can afford to waste some thousands annually because the plan proposed did not emanate from one of their own engineers? But surely after such an announcement as that which was made by Mr. Anderson in reference to the advantages realised at the Arsenal pier, I may yet hope that the Government will for once deviate from their usual course of routine, and allow the humble inventor the happiness and advantage of carrying out his own designs, and thereby afford him an opportunity of showing the superiority of his plans to those which he must ever look upon as pirated.

In the month of May, 1858, having some business to transact at the Royal Military Academy, and whilst waiting for the arrival of the Governor, my attention was directed by an officer present to a small brass cannon which is used for the purpose of drilling the cadets. In the course of conversation I was informed by that gentleman that the elevation screw employed in the service was not to be depended upon in consequence of its liability to slip after the gun is set; and so great is the inconvenience arising from these defects, that the drill sergeant is obliged to request the gentleman stationed on the left of the breech to press down with his hand upon it, in order that he may take off the weight from the screw till he has ascertained whether the elevation was correctly taken. Such being the facts, I prepared a drawing, and employed an engineer to manufacture an improved screw, supplying it with an auxiliary nut, so that by simply pressing it upon nut No. 1, the screw becomes instantly secured, nor can it possibly escape until it is intentionally relieved. Having made this discovery, I wrote to Major General Peel, Secretary at War, describing the particulars of my invention, and also pointing out to him the advantages which would be derived by its adoption. On the receipt of my letter, the General wrote to the Ordnance Select Committee, requesting them to examine the model, and report thereon. After a lapse of six months, not having heard anything either from the War Department or the Committee, I wrote again to General Peel, when I was informed by that gentleman that a 24-pounder brass howitzer had been fitted with the screw, and had been sent to Shoeburyness, where it would undergo a fair trial; and although a few hours' severe test would be sufficient to prove its superiority over those now employed in the service, yet to this moment nothing has been reported regarding its results, whilst the gun before alluded to at the Military Academy, as well as many others, still remain in the same wretchedly defective state, and, to say the least of it, reflect the greatest discredit on those in authority, who have been provided with a remedy, but who are either too reckless or too obstinate to apply it.

I now come to the main subject of my letter—the Armstrong Gun. In the early part of March last, having heard of the arrival at the Royal Artillery barracks of the gun invented by Sir William Armstrong, I hastened to the shed in which it had been deposited for the purpose of examining it, not knowing at the time that any order had been issued to prohibit strangers from so doing. On my arrival I found a man engaged in cleaning the gun; I also found that the screw and portable breech pieces were withdrawn, so that I had an excellent opportunity of examining it in all its details. Having discovered several defects, which I have enumerated in my specification, I commenced a correspondence with Major-General Peel, which has issued in a series of letters on both sides, as well as leading me to submit models and drawings for inspection and report of the Ordnance Select Committee; the result of which is, General Peel has declined to entertain my application for the Government to manufacture a gun with my proposed improvements, assigning as a reason that he cannot put the country to the expense, although I have been the means of saving the country an incalculable amount of money through the introduction of the pier already alluded to. If General Peel was desirous of concealing the principles of the construction of Sir Wm. Armstrong's gun, he has had ample opportunity so to do during the last two months which my drawings have been before him; but, as he has thought proper to return them, accompanied with an insulting letter, in which he has uttered language which he knows is void of truth, namely —"that I do not understand the principles of the construction of Sir Wm. Armstrong's gun," I now and here beg to inform him and the world at large that I not only understand the principles of the construction of the gun in question, but that I am so fully acquainted with it in all its details that I can not only produce its counterpart but also a superior article, which will accomplish twice the amount of work in any given time with a less number of men than are now employed, and which will be less liable to accident to those who may be so engaged.

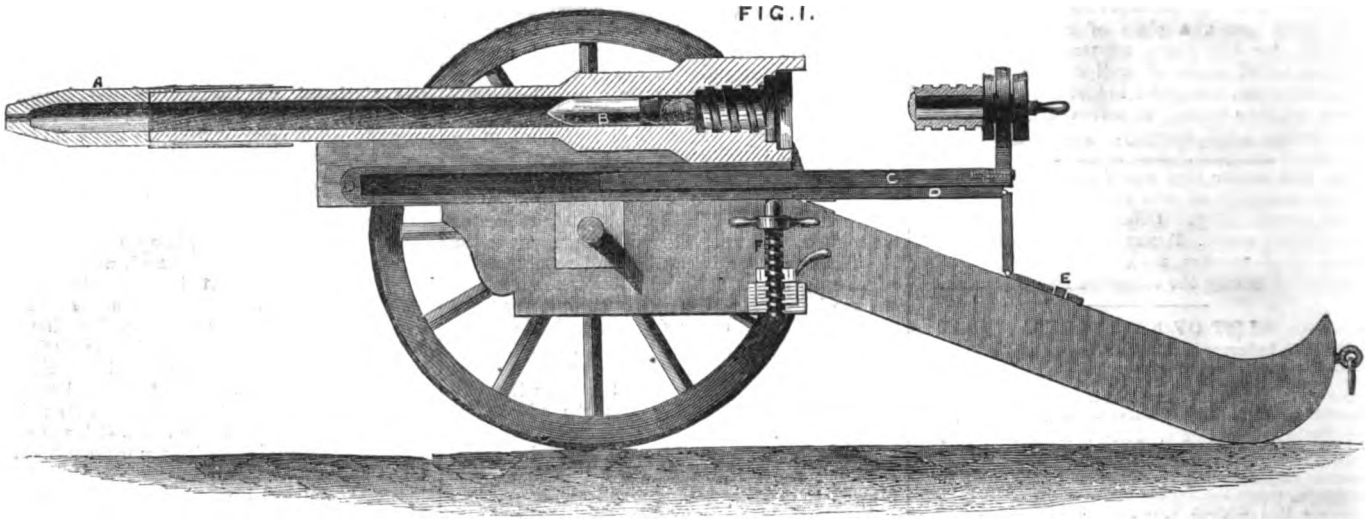
MR. GOSLING'S IMPROVEMENT UPON THE ARMSTRONG GUN, &c.

FIG. 1.



I append a copy of my specification and drawings, and beg that you will, if possible, publish both this letter and them in your Magazine.

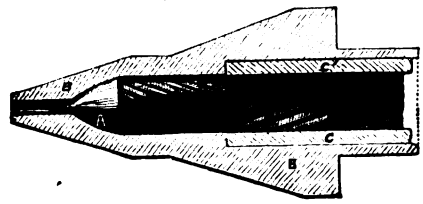
I remain, Gentlemen,
Your obliged and obedient servant,
WM. GOSLING.

82 Wellington-street, Woolwich, 11th May, 1859.

"GOSLING'S PROPOSED IMPROVEMENTS ON SIR WM. ARMSTRONG'S GUN.

"Specification of proposed improvements to be made to a rifle-cannon projectile, &c., &c., the invention of Sir Wm. Armstrong, whereby it may be made doubly efficient by delivering twice the number of shots, in any given time, than in its present state; dispensing with the sponge now used by causing each shot to cleanse the gun in its passage through the bore, and also throwing shots, varying from 32lbs to 200lbs, without increasing the size of the bore or charge of powder; by Mr. Wm. Gosling, Architect, Civil Engineer and Surveyor, 82 Wellington-street, Woolwich. In order to point out the advantages to be derived by the proposed invention it will be necessary to state that the inventor does not wish to alter the gun in question, either as regards its dimensions or calibre, but simply to correct its defects, with a view to render it a more efficient weapon for military and naval service. The defects discovered in the gun, and for which provision is hereby made, are as follows:—The portable breech-piece now employed, and which has to be removed for the purpose of charging the gun, is liable to be missing under peculiar circumstances, and, therefore, it is submitted that an improvement is of the utmost importance; hence, should the men at the gun, by accident, sudden surprise of the enemy, or any other casualty, lose the piece, of which there is considerable danger, the gun would be rendered useless; or, should the breech-screw not be sufficiently turned before the firing takes places, it would be shattered, or blown away, and could not be recovered again. Should a shot strike the handles which are used for the purpose of removing the breech-piece they would be instantly destroyed, so that the piece could not be used; or should a well-directed aim be taken by the enemy, so that the winch or lever which is employed for the purpose of working the breech-screw, the probability is, that it would be broken off, or the screw would become deranged so that it could not be worked. Another disadvantage in connection with the gun arises from the fact that the bore has to be sponged at every discharge, and after firing five times it has to be sponged *with water* in consequence of the shreds from the lead-coated shot clogging the grooves, for which purpose two water-tanks are provided and placed on either side of the gun. Now it may occur, that the army may be so circumstanced that water cannot be obtained, and, therefore, the efficiency of the gun, as now constituted, must inevitably fail; and, therefore, to send the gun into the battle-field in its present state would not only reflect the greatest discredit on the science of the British nation, but it would be a disgrace to the Government, whilst it would be attended with the most disastrous consequences to the men employed.

FIG. 2.



"Now in order to remedy the defects here enumerated, it is proposed, and also shown, in the accompanying drawings, *that everything connected with the gun shall be attached*, and therefore none of the casualties here enumerated can occur. 1st. It is proposed that the portable breech-piece shall be dispensed with, and the charge shall be entered from the end of the breech by withdrawing the screw. In order to effect this, the screw will be so constructed that by a quarter turn of the handles attached to the head of the screw and connected with the slide, it will instantly recede from the breech; by this means—namely, the screw being withdrawn at each discharge of the gun—*a current of air will pass through the bore, so that it will be kept constantly cool*. 2nd. That the sponge now in use, as well as the water-tanks, shall be superseded by the elongated shot being grooved at the end, and packed with tow, flannel, or other flexible substance, so that at each discharge of the gun, the bore will be made perfectly clean, thereby effecting a great saving of time; in fact, the gun can be fired as fast as it can be supplied with ammunition without an instant's delay, whilst a less number of men will be required to work the gun in consequence of the sponging being dispensed with, which takes the same amount of time as that employed in charging and firing the gun. 3rd. A moveable platform, constructed of oak, and strengthened with iron plates, will be hinged to the trail, so that when the gun is to be discharged by raising the platform, a traverse will be instantly formed for the slide and screw. 4th. The elevating screw by being furnished with an auxiliary nut, will be found of very great advantage, especially in night-firing; hence, when the gun is once elevated by a single turn of the nut, the screw will be instantly fixed, and the firing may be carried on during the night with the greatest precision. 5th. In order that the gun may be made available for the discharge of shots of different sizes, it is proposed that an elongated shell shall be prepared as follows:—A cylinder will be made the exact dimensions of the projectile; on this cylinder will be formed the intended shell by bending diagonally red hot bar iron 1½ by ½ over each joint of the several underlayers until it assumes the shape set forth in the drawings; the inside of the shell when cold will be coated with lead seven pounds to the square foot, so that when the lead-coated shot enters the shell, they will amalgamate, and constitute but one shot; thus, a gun of 3½ inches bore may be made available for the discharge of shots varying from 32 pounds to 200 pounds, thereby giving the gun an advantage over every other gun yet submitted, and when used in the naval service, instead of an incision being made in an enemy's vessel of 3½ in. in diameter, an aperture of 12 inches may be effected without increasing the size of the bore of the gun or charge of powder.

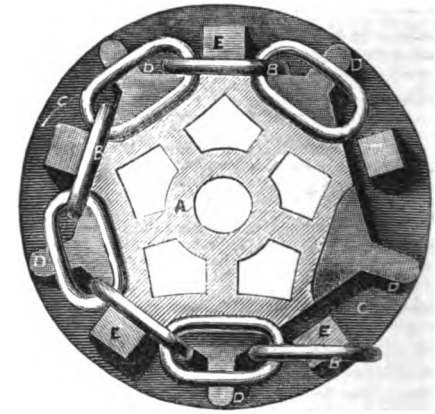
DESCRIPTION OF THE ENGRAVINGS.

FIG. 1.—*A section of shell for reception of shot to increase weight and destructiveness, also telescope slide attached; B improved sponge-tail shot; C slide and screw attached; D elevation of platform; E stop to support platform; F improved elevating screw, with its tightening nut.*

FIG. 2 *is a separate view of a portion of the muzzle C of the cannon with the ordinary shot A quitting it, and with it the large shot B for naval purposes.*

WARDILL'S IMPROVEMENTS IN CAPSTANS AND WINDLASSES.

MR. JONATHAN WARDILL, of Commercial-road-east, London, has patented an invention which consists in constructing purchases in such manner that a bite is afforded for both the horizontal and vertical links of the chain, or those links which alternately assume a vertical and horizontal position when being passed or wound over a windlass or drum. For this purpose he takes a central



piece or core, and forms round the periphery thereof, say, five concave spaces, intended to receive those links which, when the purchase itself is used vertically, pass in a vertical position. He bolts this central core between two flat-sided plates, provided on their inner faces each with as many radial chocks or blocks as there are concave spaces in the core. These radial blocks come opposite each other, and over, or in a line with, the centre of each concave space; then between the radial blocks are laid on each plate flat blocks, which form, with the radial blocks, hollow chambers, and when the chains are passing, receive those links which are presented horizontally. The radial blocks are curved or sloped off at bottom where they join the discs. In the case of open

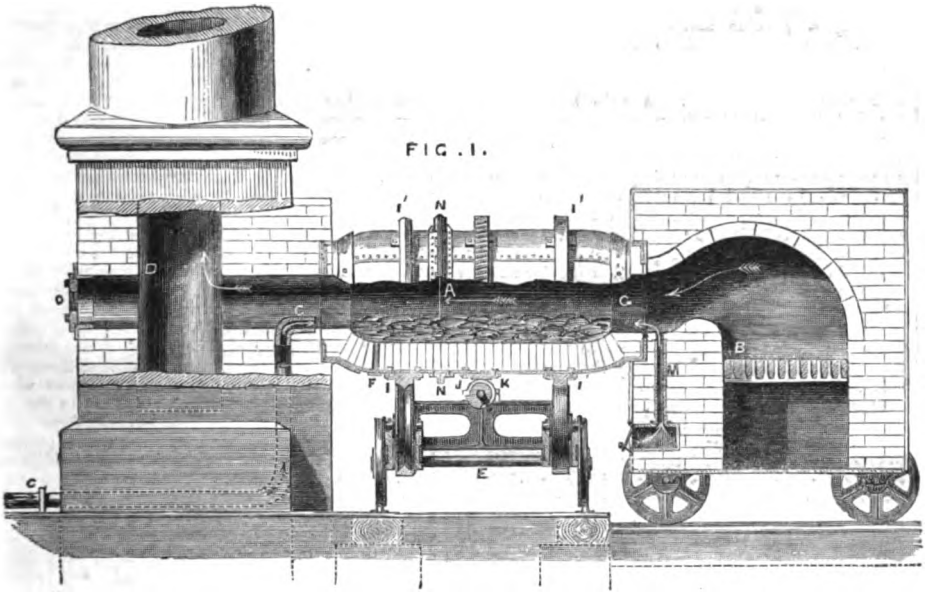
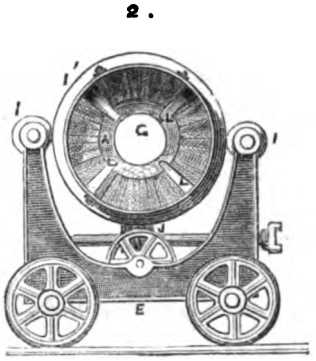
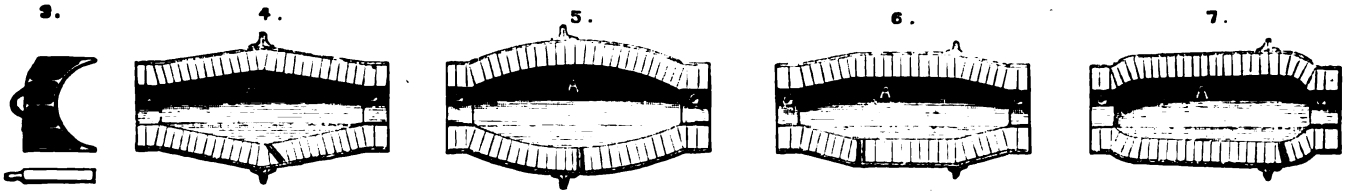
BESSEMER'S IMPROVED FURNACE FOR THE MANUFACTURE OF IRON AND STEEL.







link chains, an additional grip may be obtained by means of a tongue or projection carried up from that portion of the periphery of the core which divides or separates one concave space from another. The accompanying engraving is a section of a capstan thus formed. *A* is the centre piece or core; *B B* are the concave spaces formed round the periphery of the core; *C C* are flat-sided discs, having radial chocks or blocks *D D* formed on them; *E E* are flat blocks placed between the radial blocks. Although five concave spaces and blocks are shown, he does not limit himself to that number, as the same may be varied without departing from the essential features of the invention.

BESSEMER'S

IMPROVED FURNACES FOR THE MANUFACTURE OF IRON AND STEEL.

MR. ANTHONY BESSEMER, of Upper Holloway, has patented a set of improvements which are intended to cleanse the pig or crude iron from all its impurities, such as sulphur, phosphorus, silica, carbon, &c., and all other foreign matters, so as to produce steel and malleable iron. To effect this purpose he constructs a revolving reverberatory furnace or cylinder which is to contain the iron. This furnace or cylinder is composed of a cylindrical iron vessel made in two halves if requisite, and bolted together; both ends are to be contracted, so as to form a neck at each end, of about two-thirds or so of the diameter of the body part of the cylinder, and open at both ends. The whole interior is to be lined with segmental fire-bricks; one or more rows of bricks can be raised five or six inches higher than the rest to form a projection or projections to assist in dividing and changing the surface of the metal. The cylinder is mounted on a moveable frame capable of being moved backwards and forwards between that part of the furnace which contains the fire and the shaft or chimney. The cylindrical vessel is made to revolve the whole time the metal is under operation; the neck at each end may form the bearings. The cylinder which contains the metal, and the part of the furnace which contains the fire, form a complete revolving reverberatory furnace. The furnace part proper is of the usual reverberatory kind, and is likewise to be mounted on wheels capable of being drawn backwards and forwards. During the whole time the metal is under operation, the inventor blows atmospheric air or steam into the furnace, in such manner as to act upon the surface of the metal, so that the carbon, sulphur, phosphorous, &c., uniting with the oxygen of the air or steam may be carried off. The air or steam can be supplied by a fan or any other convenient means, and may be either hot or cold, and supplied at either end or at both ends of the revolving furnace. Although air and steam are mentioned on account of their economy, yet pure oxygen gas, or any fluid or solid matter containing oxygen gas, may be used in his process of converting crude iron into steel and malleable iron in his revolving furnace. In addition to these means of supplying the furnace with air, steam, &c., he places an air passage or pipe in the neck of the furnace proper, as near as possible to the neck of the revolving cylinder, which air passage or pipe can be made to open or shut as required Should it be requisite a rake or tool may be passed through the shaft into the revolving vessel to agitate or stir the melted metal, until the whole is converted into steel or malleable iron, as may be desired. In his revolving furnace, the usual fluxes, such as lime, silica, metallic manganese, oxide of manganese, salts, &c., may be used to advantage to assist in the separation of the various impurities which the crude iron contains.

In the annexed engravings, Fig. 1 is an elevation, partly in section, of the improved reverberatory furnace complete, and Fig. 2 is a transverse section through the cylinder. *A* is the cylinder; *B* is the furnace proper or fire-place; *C* is the pipe or tube through which the air, steam, or other like gas or vapour enters the cylinder; *D* is the shaft or chimney; *E* is the carriage on which the cylinder *A* is supported and rotates; *F* is a tap-hole, through which the metal may be drawn off from the cylinder *A*, but, if preferred, it may be drawn off through the neck *G*; *I I* are friction rollers, upon and between which the rings *I' I'* upon the exterior of the cylinder *A* run. *J* is a worm, which imparts rotary motion to the cylinder *A* through the wheel *K*, which is fixed around and upon the cylinder; *L L* (Fig. 2) are raised projections to assist in turning and stirring over the metal as the cylinder rotates; *M* is the air-passage near the neck of the furnace proper. The joint *N* shows how the two parts of the cylinder are united, when the cylinder is not formed in one. The cylinder *A* comes against the shaft or chimney on the side; *O* is a hole through which the interior of the furnace may be seen or the metal within it stirred by means of a rake or tool. Fig. 3 shows two views of a slide or plate, which fits half round the neck of the cylinder after it has been wheeled into place. Figs. 4, 5, 6, and 7 illustrate several modified forms which may be given, if desired, to the cylinder A. The operation is performed as follows:—Make the revolving cylinder moderately hot, then draw back the part that contains the fire to make room to put the crude iron through the neck into the body part of the revolving cylinder, then draw forward the fire furnace to its proper place, the fire then can be urged on as fast as possible. When the iron is red hot, or before, begin to blow into the revolving cylinder the air or steam through the pipe *C*, so as to distribute it over the surface of the fluid metal, which surface is always changing as the furnace revolves, the metal continually presenting a fresh surface for the oxygen to act upon during the whole time the metal is under operation. When the metal is in a fit state to pour, the fire furnace is to be drawn back, and the revolving cylinder is brought forward on its moveable carriage to where the moulds are placed. The metal is then to be drawn off through the tap-hole *F*, or through the neck *G*; to assist the pouring the cylinder is sometimes raised at one end. Where requisite, before pouring, the inventor places an air-tight cover on each end of the cylinder, connected by a pipe with an exhausted chamber, so as to draw off any gaseous matter that may have remained among the metal during the conversion.

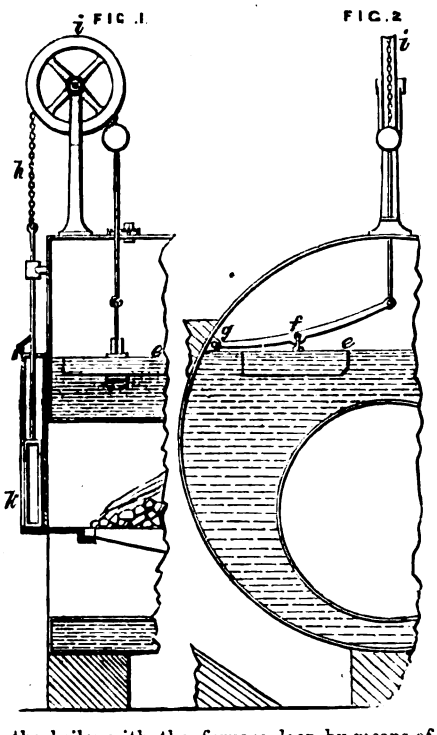
WRIGHT'S METHOD OF PREVENTING BOILER EXPLOSIONS.

MR. E. T. WRIGHT, Engineer, of Wolverhampton, has just patented the method of preventing boiler explosions by connecting a water buoy or float in the steam boiler with the furnace door, or with a door opening into the furnace, so that when the water in the boiler falls below a given level the door is opened, and cold air is admitted into the furnace, "whereby the boiler is cooled, and the draught through the fire to a great extent suspended; the overheating and consequent danger of explosion of the boiler is thereby prevented, and the attendant on proceeding to fire is warned of the state of the water in the boiler by the open door." The inventor sometimes connects the float

FIG. 1. FIG. 2.



in the boiler with the furnace-door by means of a chain and pulley, as illustrated in the engravings, Figs. 1 and 2; *e* is the float hung to the lever *f* in the boiler. The said lever *f* turns upon a fulcrum at *g*; a chain *h* passing over the pulley *i* connects the float *e* with the furnace-door *k*. By the descent of the float *e* the furnace-door *k* is raised. In boilers of the kind represented the distance between the water level and the furnace flue is sometimes insufficient to allow of the descent of the float through the requisite distance when the said float is immediately over the said flue. On this account the float is placed on one side as shown.

ON TIMBER FOR SHIP-BUILDING.

BY LEONARD WRAY.*

FROM time to time during my life I have had a great deal to do with a number of the principal timber woods of Europe, Asia, Africa, and America, which are known and classed by the timber-merchants and ship-builders of Europe; and I may moreover say, that I am very fairly acquainted with several timber woods which are almost wholly unknown in this country. With such a knowledge of these timbers, I have long been struck with the fact that, when used in the construction of ships, their accredited durability seems woefully at variance with that which we find possessed by the same descriptions of woods when they are used in various ways on shore. Timber which has the reputation of remaining perfectly sound for a hundred years and more in various structures, such as noblemen's mansions, churches, cathedrals, &c., when, for the purpose of ship-building, it is brought under the rigid classification of "*Lloyd's!*" is classed no higher, in any case, than thirteen years (in the first instance), even with all the well-defined advantages of copper fastening and other requirements indispensable in a firstclass ship! True, this term may be renewed for a further period of five years by effecting a genuine and complete "*restoration!*" but this is in general so troublesome and so expensive a course, that in nine cases out of ten the owner had better build an entirely new vessel than have recourse to it. A ship being once off the first letter at Lloyd's, very rapidly runs down the scale of her classification, unless kept up to a certain letter by constant surveys and expensive repairs; but through these I do not purpose following her. We have had instances, and those tolerably numerous, of ships, constructed of teak, mahogany, and even oak, lasting for a very long series of years, and being comparatively sound in their timbers when wrecked or broken up. On the other hand, cases are by no means rare of vessels, built even in the Government dock-yards, being—so to speak—unsound from the day they first entered the water. Indeed, we can recal instances, and might give the names of men-of-war which were said to be thoroughly rotton before they were ever launched. These speaking facts may well arrest our attention, and demand an earnest unprejudiced investigation.

No sane man will, for a moment, call in question the justice or wisdom of those rules established by Lloyd's for the building and classification of ships. But I nevertheless feel convinced that any useful and judicious experiments, tried by individuals, would always be fairly viewed and fairly encouraged by Lloyd's.

TIMBERS USED IN SHIP-BUILDING.

According to Lloyd's classification of timbers, we find that first-class comprises only the following:—The English and the African oak, the live oak of America, the mora and greenheart of Guiana, the teak and saul of India, and the iron-bark of Australia—being eight in all—of which number America supplies three; India two; and Europe, Africa, and Australia, only one each. These timbers are all close-grained and compact; hard, strong, heavy, and durable, being more or less naturally impregnated with certain oily, resinous, or astringent matters. The oaks (containing an acid and an astringent principle) are indubitably more liable to "rot" than the other named woods which abound in oily or resinous matter; hence we find ships built of the best English oak destroyed very speedily by "dry rot." I do not, however, say that even a wood so abounding in oil as the teak does not occasionally exhibit "decay;" on the contrary, experience has shown that this timber sometimes exhibits decay to an unexpected degree. On this point, however, I must beg of you to remark, that the varieties of teak are numerous, and that the character of the wood is very materially influenced by the peculiarities of climate, soil, and seasons in the locality from which it is obtained. Thus, we have the finest description of teak from Malabar; that from Travancore, from Ceylon, from Java, from the Malayan Peninsula, from the Burmese territories, and from the Tenassarim provinces. Of all these the Burmese and Tenassarim varieties are held to be the most inferior, simply because the great proportion of that shipped both at Rangoon and at Maulmain is timber grown on the rich, low, alluvial soils formed by the great rivers on whose waters they are eventually floated to market. In justice, however, to these ports of supply, I must state the fact that, both in Burmah and Tenassarim, the quality of teak, as a matter of course, varies according to the locality and soil on which it is grown. And we may therefore very fairly class the timber obtained from them as being good, better, and best. We find teak grown on high, dry, and open land, of a fine quality, being closer and more compact, and abounding in a mild, bland oil, which scarcely affects the iron bolts that may be driven into it. Whereas that grown in the dense forests of the wet, low-lying alluvials, is lighter, coarser grained, and contains an acrid oil, which not only affects iron very materially, but even, to a certain extent, poisons and inflames the hand which has been pierced by its splinters. We find also the weight and consequent specific gravity of teak varying in a most remarkable manner, viz., from a minimum of ·583 to a maximum of 1·056 (according to the experiments by Mr. Seppings;) although for all practical purposes we may take the range to be from ·600 to ·750. You are all, of course, aware that differences in situation and soil create corresponding differences in oak, in elm, and in all other English timber woods; but because teak happens to have its *habitat* in the "nethermost parts of the earth," this simple law of nature seems to be overlooked by all save by those few who have made these subjects their especial study. The greenheart, the mora, the saul, and the iron-bark, have likewise their differences, both of kind and locality, but they are by no means of so important a nature as to demand the same marked notice as I have taken in respect to the varieties of teak. These eight descriptions of timber hold, then, a very high and deserved character from Lloyd's classification, for with either of them may a first-class ship be built without the admixture of any other wood. But upwards of twenty other kinds of timber are permitted to be used in certain specified portions of a first-class ship; and some of these, at least, are no doubt working themselves up into a place amongst the highest-class woods. At first sight it may appear somewhat harsh, and even unreasonable, to place such a magnificent timber as the mahogany in the category of second-rate woods, the more so as we have had many well-authenticated instances of the extraordinary strength and durability of ships built almost entirely of mahogany; amongst which I may mention the oft-quoted case of the Spanish 80-gun ship named Gibraltar, captured by the English in 1757, and broken up at the age of 100 years, when all her timbers were found to be perfectly sound. But we must, in relation to these particular cases, bear in mind two circumstances which are in themselves all-important, viz., that in the first place, only the choicest and most superior description of mahogany was employed by the Spanish Government in the construction of the Gibraltar (which was built at the Havannah), and that no expense whatever was spared in the selection. Secondly, that such a selection of choice mahogany for the entire construction of a merchant ship at the present day would be far too expensive to suit even our princely ship-owners; whilst I need scarcely add that "swamp mahogany," or, indeed, any of inferior quality, would be highly unsafe, and, consequently, inadmissible for the "timbering" of a ship, however far it might be allowed for "inside" and "outside planking," &c. What the Crown of Spain so wisely did in days of yore has been, in my estimation, wisely imitated but a few years since by our own Government in the case of the Queen's beautiful steam-yacht the Victoria and Albert, which is, I believe, almost wholly constructed of choice mahogany, and may, with ordinary care, continue in existence long enough to carry in pleasure and safety her Majesty's great-great-grandchildren.

In ships of war, it is evidently extremely desirable to attain the highest possible range of durability; for in the peculiar circumstances of ships built for the Crown and of those built for the merchant service, there is this wide difference, that the former know not Lloyd's or its underwriters, whereas, the latter must "live, move, and have their being" according to Lloyd's, or that great body would certainly not know them or insure them. "Mahogany of hard texture" is, however, so far admitted in the construction of A 1 ships as to include beams and hooks, knees, rudder, and windlass, main pieces, outside planking to light mark, and the whole of the inside planking. As there is a pretty general misconception in respect to the specific gravity of this wood, I may observe that "superior northern Honduras is as heavy as Travancore teak, and even heavier than Malabar teak or English oak; the inferior qualities of mahogany alone being so very light and buoyant. I should be very pleased to see good mahogany enter more largely than it now does into the construction of ships; but I am persuaded that its more extended employment must be regulated with judgment and discrimination."

As may well be supposed, the cost of first-class woods is high, and the supply is not at all times equal to the demand. It is desirable, therefore, to know how the supply can be largely increased, and the cost considerably diminished. But previously to entering on that part of my subject, I must not omit to notice the silent but rapid revolution which is taking place in ship-building for the merchant service. This is not only in the increased and increasing proportion of iron used in the bracing, strengthening, and general framework of ships, but in the decided preference which even the most cautious men are gradually showing for ships built wholly of iron! Ships have been built comprising full fifty per cent. of iron, but such half-measures do not seem to satisfy the minds of men now. The great cause of "iron versus wood" is not, however, yet gained; the triumph may still be long in coming! The disastrous influence of iron upon the compasses—the treacherous character of iron plates and iron rivets—the pertinacious partiality of barnacles for iron bottoms—all these still exercise great influence upon many minds; but last, and above all, it is not the habit of our sturdy, sure-going countrymen to make any great change in a hurry. I do not hesitate to declare my own full belief that the compasses will traverse correctly—that both plates and rivets will prove steadfast, firm, and faithful, and even that the "barnacles" may be

* From the paper read at the Society of Arts on May 3rd.

Digitized by Google

effectually kept off!—yet, I should not wish to see so great a change progress otherwise than calmly, carefully, and safely;—which it can only do under the guidance of further experience and the practical success of many years. As I have expressed my belief in the undeniable suitability of iron ships for mercantile pursuits, I must, at the same time, state my opinion against them, if applied to warlike purposes. Next to the entire non-existence of a navy, I can conceive nothing so perilous to the interest and safety of this country, as having our ships of war constructed of iron! Nor can I, at present, conceive how the inventive faculties of man—aided by all the science of the age—can afford any adequate safeguard against the disastrous liabilities of a thin iron structure, such as a ship exposed on the ocean to the terrible effects of a cannonade! It is quite probable, and indeed almost essential, that the partial use of iron in the construction of men-of-war should be very largely extended, as it would add considerably to their strength, lightness, and internal dimensions; but notwitstanding this increased and increasing employment of iron, I do not see any likelihood of the demand for ship-building timber abating for many years to come; on the contrary, I fancy that I can distinctly foresee a very enormous increase for the purposes of our navy alone; not merely for the contemplated addition and conversion of our war-ships, but for the continual building of new ones, to replace those which are now being converted into screw steamers. I hold it, as the inevitable result of such conversion, that dry-rot will make swift havoc amongst them, unless the only preventive measures possible have been timely effected; but as I shall have to refer to this important point again, we will now return to the more immediate matter from which I digressed.

Increased Supplies of Ship-Building Timber.

It is not sufficient that we discover forests of timber, even of the finest quality; for before they can be turned to profitable account, we require a pupulation to fell and trim the timber, a good shipping port, and the cheapest possible means of bringing the timber from its native forests down to the port of shipment. But we require even more than this, in the majority of cases, viz., a climate such as the European Superintendents can not only exist in, but be able to expose themselves in with some degree of impunity. As a summary, then, we may consider to be essential: 1. A tolerable climate; 2. abundance of good timber; 3. A sufficient amount of cheap labour; 4. Numerous intersecting creeks and rivers to float down the timbers; and lastly, a safe and eligible port for their shipment. It is quite in vain for visionaries or enthusiasts to call attention to vast forests of stately timber, existing in regions where these essentials are not co-existing; for every man who has had any experience in such matters knows full well the numerous difficulties that beset the labours of timber-cutting gangs. Leaving, then, all the beautiful and undoubtedly valuable woods which have their *habitat* in impracticable and impossible localities, I shall bring before you those that are easy of access, and that may be transported with facility to eligible seaports. Confining myself to those woods which are, or which may yet become first class on Lloyd's books, I will first present to your notice the extraordinary capabilities of Honduras.

Even before the time of the celebrated Dampier, the cutting of logwood and mahogany had become an important business in that colony. More than 180 years have since elapsed, and still it is almost wholly known to the world for its large exports of mahogany and logwood, and for these only! During this long series of years, Honduras has had its organised bands of wood-cutters, whose peculiar occupation has descended from father to son through so many generations, that it has become a part and parcel of their very natures. From childhood to the grave, the sole business of their lives is hunting for and cutting timber in the dry season; floating it down to Belize during the rains; and enlivening that seething town with their fantastic dances and drunken revels, until their money being exhausted, they once more are obliged to betake themselves to their occupation in the dense forest. Hard and laborious indeed is their life in the bush; the felling and squaring up of the vast logs of mahogany being really the lightest portion of their task; for they have to clear away the thick and thorny underwood, cut down and remove thousands of immense trees, in order to form roads, whereon their trucks can pass with their heavy loads to some creek or river. These main and bye-roads are often miles in length, all carefully graded and rendered complete by numerous temporary bridges strongly constructed. To make these roads and bridges, a party of 50 to 60 men are detached, whilst the remaining number are preparing the mahogany for trucking. Such gangs are usually provided with from 6 to 10 ponderous trucks, having 14 oxen to each truck; and as these work only at night, by torch-light, we can readily imagine how carefully the roads must be cleared of all obstacles. When the rains set in, and their logs are floating down towards the coast, these hardy fellows follow each batch in their little pitpans, and exercise all their amphibious dexterity in securing the safe and unimpeded passage of their property. Now, I have not given you this slight sketch for the purpose of mere amusement, but because I wish in the most emphatic manner to point out the important fact that, in this colony of Honduras, we have the largest and most practical body of tropical lumberers that exist on the face of the earth. That there is now exported from that colony about 25,000 tons of mahogany and about 6,000 tons of logwood per annum. That these woodsmen, in the pursuit of these two staple products, continually pass and repass vast quantities of fine and valuable timbers, in every way suitable for ship-building. The forests in which they live and work contain some of the finest quality timber in the world, and that in extraordinary profusion. I do not pretend to know many of these woods, but the following I am well acquainted with: the greenheart, the live oak (*Bignonia*), and other oaks; the mahoe, the bullet tree, the Neesberry bullet tree, the iron-wood, the locust (used for ships' planking and tree-nails), the dogwood, the red pine, the pitch pine (much superior to that of Carolina and the other Southern States of America), the cedar (*Cedrela odorata*), a light and durable wood, not liable to dry rot nor subject to the attack of insects. The trunk of this tree is 70 to 80 feet long, with a diameter of from 4 to 7 feet. I am sure I need not dwell upon the great value of these fine timber woods, but I must again observe that there are numerous others, perhaps equally valuable, which I cannot now enumerate. It is quite clear to my mind that the Honduras woodsmen could realise a very great deal more money, and with infinitely less labour, by preparing for market these timbers than they now do from their mahogany and logwood; but as the gangs are always hired under contract by some merchant or mercantile firm in Belize, it is evident that the initiative must be taken by those enterprising gentlemen. The safest course, perhaps, would be to commence the attempt by combining the two objects, for the same roads necessary for the trucking of mahogany would serve for the transport of the other timbers selected. There is a distinguished member of this society, Chief Justice Temple, still residing in Honduras, to whom we are all indebted for the indefatigable exertions he has made to attract attention to the capabilities and resources of this fine colony, and I am sure that his advice in relation to the course I have just suggested would be particularly valuable and instructive.
